Mr. Rawlings pointed out what he considered the defect in the tubular system as exhibited by Mr. Bathurst—viz., that the tubes themselves were not flexible. Another very important point which they should remember was that they were not nail proof beneath the plaster. Testing did not find a nail unless it was in a damp place. He thought it was the duty of the Institution to stamp out the workmen who were going about—the scum of all the other trades—who called themselves wiremen. The Institution should have a method of registering men who should be supported by the members. He understood the City and Guilds Institute of London were doing something in this direction.

Mr. Human spoke from the point of view of the insurance inspectors, and devoted his remarks chiefly to a criticism of Major-General Webber's views. He admitted that many of the inspections were more or less a farce—four in nine of such inspections might well be dispensed with.

Mr. Shoolbred was very glad to see that in the table appended to his paper Mr. Bathurst had adopted an ampere test. The adoption of a lamp test was unsatisfactory, because there were not only 8-c.p. and 16-c.p. lamps, but motors and arcs to be considered. He had prepared a table on the subject, which he would hand to the secretary.

Mr. Dykes said the question of the best system of wiring was like the best engine or the best boiler—it entirely depended on circumstances of the case. Used with proper care as good insulation could be obtained with wood casing as with any other system, provided the building was suitable for it. If necessary, different systems might be used in different parts of the same house.

Mr. Crompton said it was a matter of regret that more had not been contributed to the discussion by those who had used concentric wiring.

Mr. Bathurst commenced his reply, and insisted that his system was really cheaper than wood casing. The greater part of his reply, however, he would not read, but would hand it in for publication, in order to allow of the reading of Mr. Addenbrooke's paper on high-voltage lamps, which was then proceeded with.

WHAT, WHEN, AND WHERE.

Physical Society.

February 28, 5 p.m.—At Burlington House. "Experiments with Incandescent Lamps," by Sir D. Salomons. "The Alternating-Current Arc," by Messrs. Fleming and Petavel.

Institution of Electrical Engineers.

March 4, 6 p.m.—Students' visit to the central stations of St. Pancras Vestry; meet at Stanhope-street central station, near Gower-street or Portland-road stations.

City and Guilds of London Institute.

March 5, 8 p.m.—At the Finsbury Technical College, Leonard-street, E.C. "Recent Discoveries in Electro-Optics," by Prof. Silvanus P. Thompson.

Society of Arts.

March 4, 8 p.m.—Thirteenth ordinary meeting. "Röntgen's Photography of the Invisible," by A. A. Campbell Swinton.

Electro-Harmonic Society.

February 28, 8 p.m.—At St. James's Hall Restaurant. Concert; ladies' night.

Carpenters' Hall Lectures.

March 4, 8 p.m.—At the Hall, London-wall. "Electricity in Connection with Building," by W. H. Preece, C.B.

Engineering Society.

March 6, 4 p.m.—At King's College, London. "Aluminium Extraction," by Mr. Hackman.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE TELEPHONE SERVICE.

The information elicited by Mr. Tully in the House of Commons on Monday, "that it is not the intention of the Government to take over the entire telephone service before the expiration of the present license," probably marks a new era in the telephonic history of the United Kingdom. The announcement, we have reason to know, has caused a flutter in certain quarters where the acquisition of the whole system by the Government at the next break in the license—December 31, 1897—has been looked forward to with considerable confidence. That expectation can no longer be entertained.

For reasons which we have from time to time placed before our readers, we have consistently recommended the Post Office as the only proper organisation to own and work the telephones. Admitting that the control of the telegraphs has been wisely vested in the Post Office, any other view appears illogical, seeing how closely the twin inventions are linked by their nature and practical applications. But the fiat has gone forth: it is not to be; and it behoves us to look the fact in the face, and examine with some degree of curiosity the vista which the new turn of the telephonic teetotum has opened up. From January 1, 1896, to December 31, 1911, the date of the expiry of the current license, is sixteen years. It is a long time. Within a like period the French Revolution sprung up, raged, decayed, and died. Is it expected that the present monopoly, undiluted, is to co-exist with the license? If so, we hasten to assure the authorities concerned that they are labouring under an error of no inconsiderable magnitude. Indications of rebellion against the "inefficiency and expensiveness," as Mr. Tully put it, of the National Telephone Company's service multiply apace. The city of Glasgow has renewed its demand for a license to construct and work a telephonic exchange system of its own, and Edinburgh, Aberdeen, and other Scottish towns are understood to entertain longings in the same direction. Nearly three thousand ratepayers of Manchester have expressed a desire for a municipal exchange, and although the movement has received a check, the existence of such a numerous body of malcontents is too significant to be ignored. Dover and other places are likewise in arms.

It is consequently certain that something more than a policy of quiescence must be forthcoming. The intimation that the Post Office itself will compete with its license in places where the existence of an unsatisfactory service can be demonstrated can only be regarded as of moment provided the Department is prepared to reduce its tariff by more than half. Mr. Tully's description of the present service comprises the word "expensiveness" as well as "inefficiency." Now, except in London, the National Telephone Company's charges, heavy as they are esteemed, nowhere approach the tariff for telephone exchange communication set up by the Post Office, and it seems to us ridiculous for the Department to say to a man who complains of having to pay £8 or £10 for a mile of wire, "Come over to our exchange; we will give you a

Digitized by Google

metallic circuit and charge you—£14." A more common-sense view of the situation must, we are convinced, prevail. If the National Telephone Company, which is admittedly heavily over-capitalised, pays 6 per cent. dividends on £8 or £10 rates, the Post Office, with no such drawbacks, can surely flourish on rentals of £5 or £5. 10s. per annum. It is in evidence that more than one British telephone company has made ends meet on such charges as these, even when metallic circuits have been supplied; while on the Continent £5 per annum, and even less, rewards telephone undertakers with substantial profits.

If Post Office competition cannot be made to march with low rates it will meet with neither success nor tolerance, and, dismissing it from practical consideration, it will be necessary to clear the line for municipal or private enterprise, or both. Private undertakers will, however, have to be jealously watched and all possible safeguards against a repetition of the old absorbing and "water"-creating tactics imposed. There may be difficulties in framing a license so as to prevent transfers of business, but they are surely not insuperable.

We consider, therefore, that the Government's decision leaves but three paths logically open. These are: (1) maintenance of the existing monopoly; (2) active and business-like competition by the Post Office at reasonable rates; (3) issue of new licenses, under adequate guarantees, to municipalities and local companies. The first is impracticable unless public opinion is to be openly flouted and defied; the second, in view of Post Office lassitude in the past, is unlikely; the third appears, under the circumstances, the only reasonable solution.

The insignificance of the telephone industry at home as compared with the vast proportions which it has assumed in some other countries, constitutes a standing reproach to our national character for business intelligence and enterprise which we trust is now in a fair way to be wiped out.

RESULTS AT COLOGNE.

Elsewhere we give a brief account of the results obtained by the combined working of the waterworks and electric light station at Cologne. The two works, as well as the gasworks, are under the control of the Municipality. The buildings of the waterworks pumping station and the electric light station are close together, the new boiler-house serving either or both sets of engines. Of course, the circumstances at Cologne are exceptional; but there may be cases even in England where a similar combination might be beneficial. Messrs. Feldmann and Froitzheim point out the maximum output of the two works never coincides: "The largest consumption of water takes place during the day and the summer months; the maximum output of the electric station is attained in the evening and during the winter months. The boiler plant is therefore worked at a nearly constant rate of steam production throughout the year." This is a consummation desired by all electrical engineers, though the realisation is only for the few. There may be but a small number of places where the pumping plant is the complement of the electric light plant, and where extensive reservoirs do not intervene between the pumping plant and the mains; but the success at Cologne should, where possible, lead to a consideration of a similar combination. With all due respect to electrical engineers, we none of us really believe in a system which requires machinery for a maximum output for a couple of hours out of the twenty-four, and from 60 to 80 per cent. of which is idle during the remainder of the time. Interest and dividends may be paid, but that only proves the inherent value of the system of artificial illumination, and not the perfection of apparatus employed. The cry is, Add to the day load, level up the load curve, till the machinery is blessed with a constant load; but at present, with the exception of such places as Cologne, the blessing has not been attained.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

RONTGEN RAYS.

SIR,—I do not remember having read anything referring to the following point in connection with the above subject.

It has occurred to me that possibly under powerful inductive influences the molecules of a body may undergo some rearrangement, perhaps a symmetrical or polar arrangement such as obtains in soft iron as a result of magnetic induction.

A body with its molecules thus arranged may allow certain rays to pass through it which it otherwise would not do, and possibly under these conditions the body would allow some of the rays of ordinary light to pass through it.

It has been stated, I believe, that the X rays are not refrangible, and are not, therefore, included in ordinary light rays; but is it not possible that some of the latter rays may refuse to undergo refraction?

Perhaps some of your readers can give some interesting information on these points.—Yours, etc.,

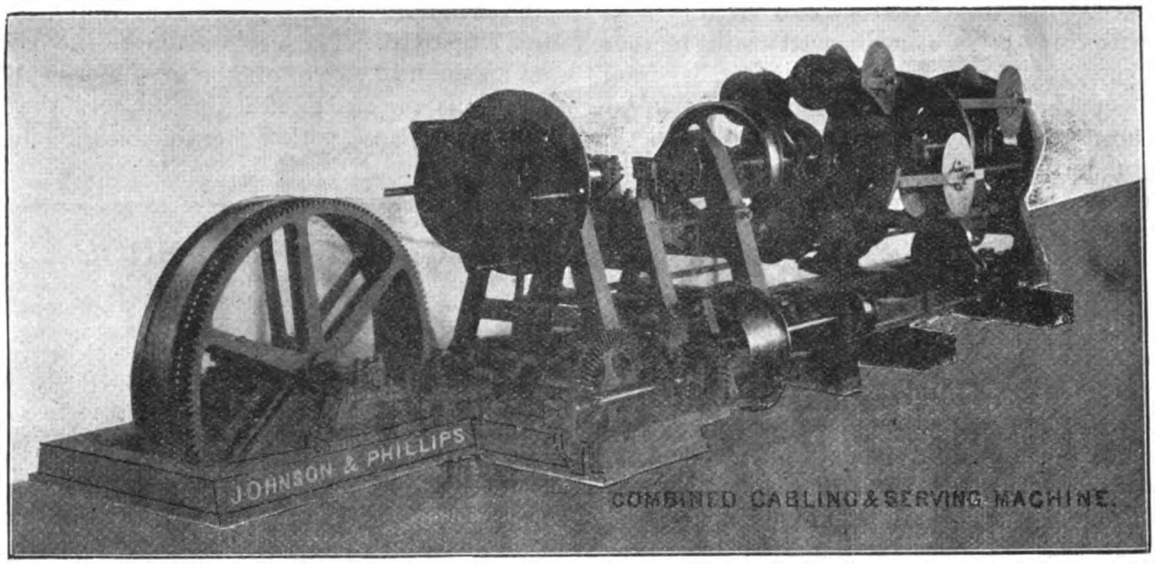
O. J. PRESTON.

COMBINED CABLING AND SERVING MACHINE.

Some time ago we promised our readers particulars of a machine of this description as supplied by Messrs. Johnson and Phillips, of Charlton, to H.M. Postal Telegraph Department for cabling their guttapercha-covered cables and at the same time serving them with compounded tape. This machine, which we now illustrate, is arranged for cabling seven wires—*i.e.*, laying six wires round one, and at the same time laying a yarn in the recess formed between each pair of wires, so that when the cable is taped it forms a more perfect round. The machine is erected on a strong cast-iron bedplate, and the six wire bobbins (arranged in two bays) are carried in forged wrought-iron flyers between three discs, the third disc also carrying the six yarn bobbins. The central hollow steel shaft runs in a large gunmetal stepped bearing at one end, and the "lay-head" end and the centre disc run on anti-friction rollers. The draw-gear is driven from the "lay-head" end of this shaft by means of a belt driving on to a countershaft carried from the bedplate of the machine. The motion is transmitted to the draw-through drum by means of spur and bevel gearing, change wheels being provided to give the requisite length of "lay" for the different sizes of wires. The taping head is designed to serve various widths of tapes, and for that purpose is driven by means of coned pulleys, which allow the "lay" and "lap" of the tape to be adjusted very minutely. The bobbin of tape, as will be seen, is arranged concentrically with the cable, the tape

Digitized by Google

being led from the bobbin by means of a series of rollers, etc., down through a slotted guide on to the cable. The wire bobbins are each arranged to hold one mile of gutta-percha-covered wire, and the yarn and tape bobbins respectively hold sufficient tape to "worm" and "serve" this length of cable. The diameter of the tape bobbin is 21in.; the radius described by the taping head, measured over the guide-rollers, is 16in.; and the speed of this head is about 500 revolutions per minute. The central hollow shaft is 3in. diameter, and runs in large gunmetal stepped plummer blocks having bearings 2½ diameters long. All the bobbins are provided with means for adjusting the tension on the various wires, yarns, etc., as may be desired. The finished cable is led from the draw-through drum on to a receiving drum placed a few feet distant from the cabling machine, from which it is driven by means of a belt. This apparatus is provided with an automatic guiding-on and flaking gear, which is not shown in the illustration.



Besides the above-described machine, we understand that Messrs. Johnson and Phillips have supplied H.M. Postal Telegraph Department with a four-wire combined cabling and serving machine all complete with the necessary bobbin winders, swifts, and automatic winding and coiling gear for making the finished cable up into coils, and have fitted it up at the Mount Pleasant factory.

THE DEVELOPMENT OF ELECTRIC LIGHTING ENGINES.

BY H. LINDLEY.

This paper, which was read on Monday last before the Northern Society of Electrical Engineers, is an interesting account of the varous difficulties overcome in the development of high-speed engines. Mr. Lindley commenced by dividing electric lighting engines into three classes—viz., slow-speed, moderate-speed, and high-speed. The engines to which this paper refers are what may be called ordinary engines—viz., having cylinders, pistons, etc.—and the speed referred to is the speed of rotation of the crankshaft.

The author proceeded to point out that the piston speed in these three classes of engines mentioned does not vary much. The old method of choosing engines for a given work by trial and error was then discussed, with the improvements demanded by the Lancashire millowners. As soon as it became evident that electric lighting was likely to require the services of a large number of small-sized steam-engines, nearly every maker of them suddenly awoke to the fact that his particular make of engine was particularly suited for electric lighting work, and advertised the fact. The wish, however, was but father to the thought, and as soon as one of these engines was set to do the work that by calculation it should be equal to doing, and which also by exact calculation it was known to have to do, the crank-pin got hot. An extra large-sized lubricator was fitted to the crank-pin, and the engine was advertised as being specially designed and equipped for electric light work. But still it did not do. Why then did engine builders still persevere till they did produce an engine that would do the work it should do, when all the time there was the slow-speed mill engine waiting and willing to do it? The author's opinion was that, apart from other obvious reasons, there was the great question of cost; the slow-speed engine was too dear.

The author then discussed the modification introduced in the modern engines, such as the shortening of the stroke, the increased surface in the bearings, improved lubrication, the almost universal adoption of white metal in the bearings, etc. He also referred at length to troubles arising from the use of thin lock nuts for adjusting the big end bolts of the connecting-rods and the slide-valves, and to the mechanical details of the cross-heads and pistons.

Another point that deserved attention was the valve. That might be either of the flat or piston type. The flat valve had the advantage of cheapness and steam tightness, but it took more power to drive than the piston-valve, which was a consideration where automatic expansion by means of a shaft governor was used. The author then took up the important question of engine governing, and after careful consideration advocated a crankshaft governor on the grounds of safety and efficiency. He then returned to the question of speed, and explained that a high speed was a great advantage, and for the simple reason that direct communication with the dynamo was possible, and all other means of transmission were avoided. Although direct coupling was used with moderate-speed engines, the dynamos were then large and expensive. On account of centrifugal strains he did not think that any great increase in speed would be attained over the present practice.

The high-speed engine could, no doubt, be made very economical, if only on account of its high speed and the consequent higher temperature of its cylinder walls, but it was more susceptible to derangement from careless use, and if a breakdown of any part should occur the results would be more disastrous than in a slow-speed engine. Water, in particular, was a source of the greatest danger, and a separator was therefore usually fitted to that class of engine.

One point to which Mr. Lindley called attention in concluding the paper was that the electrical industry had created a demand for new and improved types of engine attendants, and that the old easy-going mill-engine tender, with hardly a care to trouble him, had in central electric light stations to give way to a man who was constantly on the watch lest anything should go wrong, and who was alive to the importance of maintaining a steady and uninterrupted working of the plant under his charge. Marine engineers knew what that meant better than those in charge of stationary engines; but the advent of high-speed steam and dynamo-electric machinery that must be kept going, had necessitated vastly increased watchfulness and care from those in charge, to what obtained only a few years ago.

The paper was well received, and is worthy of careful reading.

NOTES ON STEAM SUPERHEATING.*

BY WILLIAM H. PATCHELL.

Nature of Steam Superheating.—Superheated steam is steam of any pressure at a temperature higher than the temperature of its evaporation from water at that pressure. Saturated steam may be superheated by imparting additional heat to it at a constant pressure, during which process its volume increases. By permitting saturated steam of a given pressure to expand

* A paper read at the Institution of Mechanical Engineers. [We regret that we are obliged to condense this valuable paper.—ED. *E. E.*]

Digitized by Google

without doing work superheated steam at a lower pressure may be formed. Steam cannot be superheated in the presence of the water from which it was evaporated, owing to the fact that the water takes up the heat and evaporates into further saturated steam. The corollary follows that water cannot exist in the presence of superheated steam; either the surplus heat in the steam will evaporate the water, or, if there be too little surplus heat to evaporate all the water, the steam will immediately become saturated by evaporating as much of the water as it can.

Messrs. Fairbairn and Tate, Hirn and Siemens, all found that saturated steam was not a true gas, but that when a temperature of about 20deg. F. above that of the saturated steam was reached the volume increased at about the same rate as that of a perfect gas. A marked feature in the use of superheated steam is the rapid fall in the superheat from radiation, etc. The reason of this more rapid fall in temperature as compared with saturated steam seems to be that the latter owes its heat-retaining properties to the water spray carried in it. It is only after this water spray has been evaporated that the steam becomes a true gas.

Aim of Superheating.—The greatest advantage to be gained by the use of superheated steam in engine cylinders is due to the immediate absorption of the film of water on the metal surfaces by the surplus heat, thereby counteracting cylinder condensation, which is the heaviest loss in the expansive working of steam. In this connection superheated steam would appear to have an advantage over steam-jackets, inasmuch as the heat is applied exactly where it is wanted, and during the period that it is wanted—that is, up to the point of cut-off—whereas a steam jacket wastes a considerable part of its heat n warming up the exhaust.

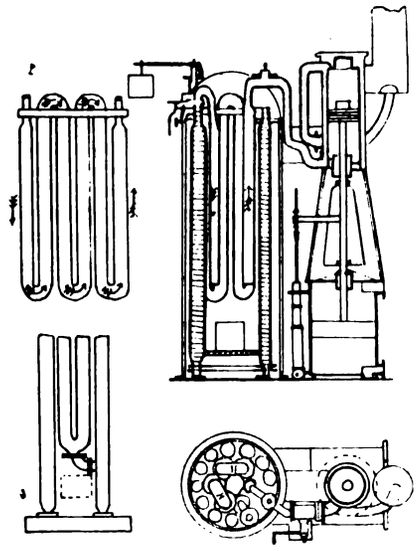


FIG. 1.—Trevithick Superheater.

Early Attempts at Superheating.—That economy attends the use of superheated steam in engine cylinders has been known at least since 1828, when Richard Trevithick reported on the engines at Binner Downs Mine in Cornwall. The engineer of the mine, Captain Gregor, built in his cylinders and steam-pipes with brickwork, making a fire-grate underneath them and flues around. The results were unexpected, and the duty of the engine was raised from 41 to 63 million foot-pounds per bushel (84lb.) of coal. Trevithick tested the 70in. cylinder engine, which when five bushels of coal was burned in 24 hours under the cylinder took 67 bushels under the boiler; when no coal was burned under the cylinder 108 bushels of coal was used under the boiler for the same work, showing a saving of one-third of the coal by superheating. The steam presssure was 45lb. per square inch, and the strokes eight per minute. Trevithick followed this up by inventing in 1832 a tubular boiler combined with a superheater between the boiler and the engine cylinder; he also jacketed the cylinder with the waste gases from the furnace. In Fig. 1 is shown the arrangement, copied from his patent No. 6,308 of 1832. The external series of vertical pipes, connected top and bottom to a hollow ring, constitute the boiler; the superheating pipes inside it are formed like inverted syphons, so as to avoid jointing at the lower end next the fire. Owing, doubtless, to the difficulty in controlling the temperature imparted to the steam, superheating made but little headway till 1850, when it came to the front again. Many plans were then proposed for superheaters and steam-driers in various forms, both attached to boiler flues and separately fired. Asbestos packings and brass bushes with plumbago plugs were then introduced to meet the demand for steam-tight glands under superheated steam.

More Recent Efforts.—Some results then obtained were reported to this institution by Mr. John Penn in 1859 (*Proceedings*, p. 195), followed by Mr. John N. Ryder in 1860 (p. 22). Mr. Penn described the apparatus employed by him in the Valetta steamer of the Peninsular and Oriental Company, with engines of 260 nominal horse-power, where the saving in fuel due to superheating was 20 per cent. Mr. John N. Ryder dealt with Messrs. Parson and Pilgrim's apparatus as fitted on marine boilers, and also Mr. David Patridge's superheater. The Parson and Pilgrim apparatus consisted of two horseshoe pipes fixed over the fire-grate in the internal flue of the boiler. Tests on the steamers "Osprey" and "Swift" showed a saving over saturated steam of 30 to 40 per cent. in fuel. Following closely on Mr. Ryder's paper was one read by the Hon. John Wethered, of the United States, at the Institution of Civil Engineers (*Proceedings*, 1860, vol. xix., p. 462), wherein he animadverted on the futility of the common kinds of superheater, and strongly advised mixed or combined steam, which he claimed to have introduced from America four years previously.

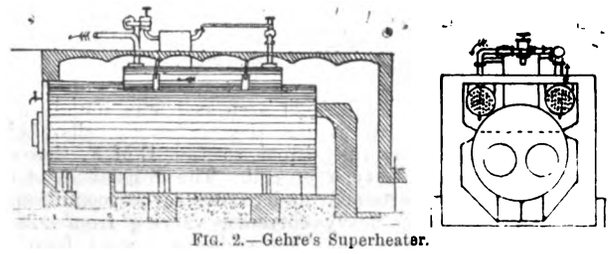

FIG. 2.—Gehre's Superheater.

Reasons for Former Abandonment.—If superheating was so common and of such manifest importance and efficiency in the saving of fuel some 40 years ago, the question arises why was it given up, and what factors that led to its abandonment have been eliminated in modern practice? Trouble was formerly experienced at the valve faces and in the cylinders from the decomposition and destruction, at the high temperatures of superheated steam, of the tallow and the low-class lubricants then in vogue. On this score, however, no trouble need now be anticipated at any degree of superheat likely to be attained where good hydrocarbon oils are used. Much of the trouble that has been attributed to the effects of superheat, in respect of cut cylinders and valve faces, has in the author's opinion been due in reality to the effect of alternate superheat and water in the steam, owing to want of proper control of the superheaters. The majority of the old troubles were met with in the engines; but the superheaters themselves do not appear to have been always above reproach.

Reintroduction of Superheating Apparatus. — Concurrently with the increased efficiencies gained in late years in both boilers and engines, competition has also increased; and with it has arisen the continual cry for cheaper power, cheaper transport, cheaper means of production. The result is that engineers cannot afford to dismiss without careful examination the claims of any plan the adoption of which may diminish their consumption of fuel. It is this fact which has again brought superheating to the front, and has made it the subject of close enquiry in many quarters. Several kinds of superheater are now in more or less extensive use; but only one of them is a radical departure from those of 40 years ago. Any change in the others is rather in manufacture than in design.

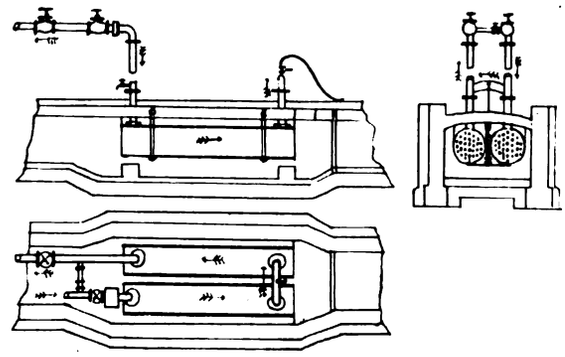

FIG. 3.—Gehre's Superheater

Gehre's Superheater.—This is in extensive use on the Continent, and has been introduced into this country by Messrs. B. Donkin and Co., of Bermondsey. It is shown in Figs. 2 and 3, and may be either fitted in the boiler flue or separately fired. Mr. Bryan Donkin kindly gave the author a copy of a test made in Germany, of eight hours' duration, on a water-tube boiler with and without the superheater. The heating surface of the boiler was 861 square feet, and of the superheater 646 square feet. The superheater was placed directly behind the boiler in a special flue. The result of the tests, which were carried out at 110lb. pressure, show a saving of 34 per cent. of coal, but 5 per cent. more steam was used on the trial without the superheater.

(To be continued.)

DR. LESSING'S DRY BATTERY.

The following is abstracted from reports by Dr. R. Mullineux Walmsley, F.R.S.E., M.I.E.E., on tests made on the Lessing battery :

Dr. Lessing's cells belong to the well-known type of modified Leclanché cells, the depolariser being black oxide of manganese and the exciting fluid sal-ammoniac. Each cell is contained in a neat porcelain outer cylinder or jar highly glazed, and is securely sealed up. Lugs on the carbon and zinc plates project through the seal, and are provided with convenient binding screws for making connections. The height of each cell is 6·3in., and its external diameter 3·1in., whilst the weight averages about 3lb. 2oz. The arrangements for so sealing the cell that the moisture cannot creep or escape, and the necessary vent for the gases that may be set free, appear to be admirably adapted to the objects in view, and have responded very well to the preliminary tests. Further tests designed to break down these arrangements tried them still more severely.

The tests were made upon three cells taken at random from a large parcel. The E.M.F. of each cell was found to be 1·470 volts, the variations on the different cells being inappreciable. This is fully equal to the E.M.F. that can be expected from this type of cell. The resistances of the cells were next ascertained under very severe conditions—viz., when generating heavy currents, varying from 2·25 to as much as 3·75 amperes. The resistances were found to have the following very low values for the above size of cell: No. 1 cell = ·222 ohm, No. 2 cell = ·166 ohm, No. 3 cell = ·121 ohm. Each resistance given is the mean of four measurements taken with currents varying within the above-named limits.

The cells were then discharged in series through a constant external resistance for 45 hours continuously, the currents given varying from 113 milliamperes at the start to 36 milliamperes at the end of the test. These currents are much larger than the cells would ordinarily be called upon to give, and the fact that they were maintained for such a long period without the cells being allowed to recuperate by intervals of rest augurs well for the practical use of the cells. Measurements of E.M.F. and resistance were made at intervals during the discharge. The details need not be given in this preliminary note, but it may be stated that at the end the E.M.F.'s were 76·2, 78·7, and 74·7 per cent. of their respective values at the beginning of the test, whilst the average resistance had only risen to a little over 0·4 ohm per cell.

The cells were next allowed to rest for five days, during which the E.M.F.'s returned to 99·0, 99·4, and 92·9 per cent. respectively of the before-named initial values. On discharging continuously for a further period of 24 hours through the same resistance as before, the current fell from 108 milliamperes at the start to 80 milliamperes at the end of the time. Simultaneously the E.M.F.'s had fallen to 72·3, 74·0, and 68·8 per cent. respectively of the value at the commencement of the first test.

In the next test three cells were discharged through a constant external resistance, which was such that the current at starting was 435 milliamperes, a very large current to take from cells of this size. Notwithstanding this, the cells maintained the current for rather more than six hours, during which time the fall of the current was less than 7 per cent. Shortly afterwards the cells fell off very rapidly, but their resistance at the end of the six hours was less than 0·2 ohm per cell.

Three fresh cells were then discharged through a larger constant external resistance, such that the value of the current, after the cells had been at work a few minutes, was 42·5 milliamperes, a value approximating to the currents usually required from cells of this kind. At 27·2 hours from the commencement of the test the current had fallen to 39·4 milliamperes (92·7 per cent. of the above starting value); at 48·7 hours it was still 39·4 milliamperes; at 71·1 hours it had fallen to 37·3 (87·7 per cent.); and at 95·5 hours to 27·6 milliamperes. This last low value was due to the fact that one of the cells had become exhausted. This cell was, therefore, now cut out of circuit and the external resistance reduced to two-thirds of its value for the three cells. The current from the two cells then rose to 37·6 milliamperes (88·5 per cent. of the first value), and only fell to 26 milliamperes at 170 hours from the start. The two cells were now practically equal in E.M.F. and resistance, and though the discharge was continued for nearly 22 hours longer it is unnecessary to quote further measurements, as for all practical purposes the cells were exhausted.

In the set of tests now being described the resistance was less than 0·2 ohm for each cell at starting, and remained at that value for over 24 hours. It then began to rise irregularly and in different ways in each cell till at the end of 48 hours it was about 0·5 ohm per cell. At the end of 72 hours it had fallen in two cells, but had risen to over one ohm in the third, which was the cell cut out 24 hours later. In a general way, it may be said that the resistance fluctuated about the value of 0·5 ohm per cell until the cells were exhausted, and that the rise of resistance was a sign of approaching exhaustion more marked at first than the fall of E.M.F.

Further tests showed that with cells in good condition currents of from 25 to 28 milliamperes may be taken continuously and without breaking circuit for 260 hours or longer, a result which may certainly be regarded as very satisfactory.

Intermittent-Current Tests.—One of the chief uses of this type of battery is not for the supply of continuous currents, but for generating intermittent currents. It was therefore desirable to examine the behaviour of the cells when supplying such currents, but still under conditions more rigorous than would probably be exacted in actual practice. A piece of simple apparatus driven by clockwork, but which it is unnecessary to describe in detail, was therefore constructed, by which the circuit of a battery could be kept closed for four minutes, and then opened for the six following minutes, to be again closed for four minutes and opened for six, and so on for as long as was considered desirable. Two tests were made with this apparatus with different internal conditions. The results were as follows: In the first series the cells were allowed to discharge through a constant external resistance, such that the current at the end of the second four minutes was 258 milliamperes—a heavy current to take from such a battery for any extended period. The tests were continued for 96 hours. Before any current had been taken from the cells their E.M.F.'s were 1·505, 1·490, and 1·476 volts respectively, and the resistances after the above current had flowed for a few minutes were 0·54, 0·49, and 0·10 ohm respectively. At the end of 49 hours the E.M.F.'s had fallen to 79·8, 78·8, and 83·0 per cent. of their initial values, whilst the resistances had increased some 50 per cent.; at the end of the 96 hours the E.M.F.'s were 71·0, 62·7, and 52 per cent. of their initial values. It is evident that at this time the battery was practically exhausted for this method of working.

In the second test the resistance was such that the commencing current was 27·6 milliamperes. At the end of 167½ hours, throughout which currents of four minutes' duration were followed by rest intervals of six minutes, the current had only fallen to 26·4 milliamperes. The cells were next allowed to rest for some days and were then again discharged through the same resistance. The current started at 27·2 milliamperes, and at the end of 213·4 hours' further work had only fallen to 25·0 milliamperes. Thus, after 380 hours of intermittent working, the current from the three cells through a constant resistance had only fallen 9·6 per cent. of its initial value.

Comparing, however, with the corresponding continuous-current tests, we find that about the same percentage fall of current occurred after 308 hours' intermittent working as after 70 hours' continuous working. In 308 hours the current is actually on for 123 hours. Now, in the "continuous" tests the cells continued to give a good current for about 280 hours, or 4 × 70. If we assume the proportion to hold, it would have taken 1,200 consecutive hours to exhaust the cells by the intermittent working. The calculation, though on a probable basis, must only be taken as approximate. Returning to the "intermittent" tests, it was found that the percentage fall of E.M.F. was fractionally (but very slightly) greater than the fall of current, because of the falling off in resistance referred to below.

The above tests show conclusively that these cells are admirably adapted for generating intermittent currents of the magnitude usually required for many purposes, such as telegraphy, telephony, ringing electric bells, and for medical and other uses. The cells, for their size, have, as a rule, a very low internal resistance, and consequently a high efficiency, since only a small proportion of the electric energy is lost in working against the internal resistance. They also have good recuperative power, and if the outside be kept dry the terminals are very well insulated.

One other important property of Dr. Lessing's cells may be referred to in conclusion. Throughout the tests, even when the heaviest continuous currents were being taken, in no instance did a cell show any sign of bursting or of mechanical leakage. In this respect they compare favourably with some similar cells on the market which the writer has seen burst open by the expansion of the materials caused by the heat generated by heavy currents.

Dr. Walmsley concludes the report by acknowledging the help of three of his students (Messrs. J. H. Hughes, C. A. Henderson, and M. Thomson) at the Heriot-Watt College, for the care taken in making the experiments, and to the two first-named for constructing the special apparatus required for the intermittent tests.

The agents for the battery in this country are Messrs. Krupka and Jacoby, 15, Queen-street, E.C.

THE PHYSICAL SOCIETY.

The annual general meeting of this society was held on the 14th inst., Captain W. de W. Abney, president, in the chair.

After a discussion on the financial status of the society, the officers and council for the ensuing year were elected as follow: President; Captain W. de W. Abney, R.E., C.B., D.C.L.,

Digitized by Google

F.R.S. Vice presidents: Mr. Shelford Bidwell, M.A., LL B, F.R.S.; Major-General E. R Festing, R E., F.R S; Prof. J. Perry, D.Sc., F.R S; Mr. G. Johnstone Stoney, M.A., F.R.S Secretaries: Messrs. T. H. Blakesley, M.A., M.I.C E, 3, Eliot-hill, Lewisham, S E, and H. M. Elder, 50, City-road, E C. Treasurer: Dr. E Atkinson, Camberley, Surrey. Demonstrator: Mr. C. Vernon Boys F.R.S The other members of council are: Messrs. Walter Baily, M.A., C. V. Burton, D Sc., L Fletcher, M A., F.R.S. R. T. Glazebrook M A, F.R.S., and Prof. A. Gray, M.A., Mr. G. Griffith, M.A., Profs G. M Minchin, M A., F.R S., W. Ramsay, Ph.D., F.R.S, S. P. Thompson, D.Sc., F.R S, and S. Young, D.Sc., F.R S.

The **Chairman** having read an obituary notice of the late Right Hon. T. H. Huxley, the meeting was resolved into an ordinary science meeting, and a paper on "**The Determination of High Temperatures by the Meldometer,**" by **Prof. Ramsay** and **Mr. Eumorfopoulos**, was read by the latter. The meldometer, an instrument invented by Dr. Joly, of Dublin, consists essentially of a thin platinum strip which can be heated by the passage of an electric current. Small fragments of a solid substance are placed on the platinum strip, and the temperature at which they melt is deduced from the length of the platinum strip, which has been previously calibrated by means of solids of known melting point. The authors have used gold for the purpose of calibrating the strip, and have assumed Violle's value—1,045deg. C.—for the melting point. A number of measurements have been made of the melting point of salts of sodium, lithium, strontium, barium, calcium, and lead The results obtained, however, differ considerably from those of Haycock and Neville, and the authors have not been able to account for these differences.

Prof. Ramsay said the chief advantage of the meldometer was that only a very minute fragment of the substance was required for the measurement, so that extreme purity of the sample could be secured. There was the disadvantage, however, that many substances underwent some change when heated in air. In reply to a question from Mr. Blakesley, Prof. Ramsay said that the property of the platinum which was used to measure the temperature was its expansion.

Mr. Campbell asked whether the zero of the instrument was found to be constant. In Cardew voltmeters it often took several hours for the needle to come back to zero after heating.

Mr. Eumorfopoulos, in reply, said that the zero was constant to within ½deg.

COMPANIES' MEETINGS AND REPORTS.

CITY OF LONDON ELECTRIC LIGHTING COMPANY, LIMITED.

The annual general meeting of this Company was held on Friday last at Winchester House, E.C., Sir David Salomons, chairman of the Company, presiding.

The **Chairman**, in moving the adoption of the report and accounts (a copy of which appeared in our last issue), remarked that 3½ years had barely gone over their heads since the Company had started. It was in September, 1892, that they took over the pioneer company, with its unexpended capital and a few street lamps erected in Queen Victoria-street and other parts of the City, but no private lamps. By the end of that year, however, they had connected and were supplying with current 20,000 private lamps with the pioneer company's machinery. During the first two years the demand for lamps was so great that they had considerable difficulty in meeting it, and, besides, they were placed at the disadvantage of having to learn the peculiarities of the district they supplied. This experience had now been obtained, and they were able to tell almost from hour to hour what was likely to be required of their plant. The first two years might properly be regarded as the construction period, and although the whole of their machinery was not yet in place, they were in a very different position last year from what they were in the two preceding years. At the present time they had under one roof the largest installation in existence, and he had every reason to believe it was of a thoroughly satisfactory character. Their machinery would be no longer working under the disadvantages of a temporary roof and the dust and dirt incidental to unfinished buildings. From the support they had received there would be no doubt that the Company would be a success, and it might now be regarded as established upon a thoroughly sound basis. With reference to their treatment of the depreciation fund, the strength of their position was that they had done work which could not earn them any money during the year, but which rendered it certain that they would be able next year to meet the parliamentary depreciation fund without calling upon their premiums again, and would probably have a surplus over. They had erected a much larger installation than had been as yet taken advantage of and it would be scarcely fair to charge the whole of the depreciation of that installation to the profits of a single year. The money had not been spent, but only transferred so as to meet the parliamentary requirements. After referring to further items in the accounts, the Chairman said the question of the telephone tubes was gradually settling itself. Owing to the great demand for the supply of current in the City it had been necessary to use a good many of these tubes for their wires, but they had still some they would be pleased to sell or lease to the Telephone Company. But for these tubes it might have been necessary to open the streets a second time. An action against the Company for vibration had been settled by the purchase of the property out of which the complaint arose, and every effort was made to prevent annoyance to their neighbours at the generating station. As to a suggestion which had been made by certain shareholders respecting the payment of an interim dividend on the ordinary shares, he said that at present the directors were unable to adopt such a course, and he himself thought it might be some years before such a proceeding would be thoroughly safe so far as the ordinary shares were concerned. Their accounts were made up to December 31, and it would be very inconvenient if, after paying a dividend on the first half-year, they subsequently discovered that it had not been earned. In electric light working the second half-year was a better one than the first. The Board, however, realised that the shareholders might desire to know how the Company was progressing, and the Board would therefore be quite willing to issue to them a circular giving that information at the half-year. It was proposed to increase the auditors' fee from 100 guineas to 125 guineas, and he might say that suggestion had come from the Board, and not from the auditors.

The **Earl of Suffolk and Berkshire** seconded the adoption of the report.

Mr. Waller asked if anything had been done as to lighting the lesser streets of the City; and **Mr. Herring** pressed the subject of an interim dividend, as to which some conversation followed.

In reply the **Chairman** said that, as he had explained, fixed charges and other expenses absorbed nearly all the money earned during the first six months, and that their dividend was really earned in the second half of the year. The question of lighting the minor streets of the City was still under consideration. Their engineer (Mr. Bailey) was in negotiation with the City authorities on the subject, and the Board were anxious to get the contract settled.

The resolution was then carried unanimously, as well as formal resolutions for the dividends at the rate of 6 per cent. on the preference and 5 per cent. on the ordinary shares for the year.

A motion to change the hour of the general meeting from 2.30 to 12.30 was lost, and the retiring directors and auditors having been re-elected the meeting ended with the usual votes of thanks.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION, LIMITED.

The annual general meeting of this Company was held on Monday at 2, Craig's-court, W.C., Mr. G. H. Brougham Glasier, chairman of the Company, presiding.

The **Chairman**, in moving the adoption of the report and accounts a copy of which appeared in our last issue, said that if shareholders compared these with the accounts of the previous year they would find that their business had been a continually prosperous one. In all items where a decrease of expenditure was desirable there had been a decrease, and as regards the output of the Company the increase had been a most satisfactory one. The actual increase in their business was equal to 25 per cent. of the number of lamps supplied, and in this respect it had almost doubled itself in the past two years. As they were aware, the price per unit had been reduced, but no doubt this reduction had commended itself to their consumers, and was not without its influence in the popularising of the light. One point about the Company's supply the speaker called attention to was the regularity of the pressure maintained; their pressure did not jump about as did some of the London supply companies, and it was very satisfactory to the Charing Cross Company to find it so. This was a matter of very great importance in connection with electric lighting, because if the pressure jumped about, not only was the light uncertain, but the lamps would not stand for so long. Notwithstanding the competition they had had to contend with, not a single customer had left them to go to their competitors. The station had been maintained in a high condition of efficiency. Out of the past year's earnings they had transferred £3,000 to depreciation account, which now amounted to £5,300. This transfer had had to be made, to comply with the Board of Trade regulations, before arriving at their net revenue With regard to the provisional order which they had applied for, for a very much larger area, it was granted by the Board of Trade, and their Bill for confirming the grant passed the House of Lords last year. Owing, however, to the dissolution of Parliament, it did not get into the House of Commons, but he believed that it would be in that House in about a fortnight. They had had to meet rather strenuous opposition in connection with it from the Metropolitan Company, but they had little doubt they would obtain their Bill. They wanted more room in order to be able to deal properly with the amount of electric energy they had to supply, and they had obtained new premises in Commercial-road, Lambeth. These occupied an area of nearly three-quarters of an acre. The site was a very eligible one for a generating station, as it had a river frontage, so they would be able to deliver their coal and other things alongside, and they anticipated that they would be able to effect a saving in the cost of production. The Chairman then moved the resolution for the report, accounts, and payment of a dividend of 6 per cent. for the half-year, making with the interim dividend, a payment of 5 per cent. on the year.

Mr. Hillhouse seconded the resolution.

In reply to questions from shareholders, the **Chairman** added that the Board did not at present know what the expenditure would be in connection with the new station, but it would be kept down to the lowest possible sum, having due regard to the efficiency and stability of the work. They had arranged for the new capital they would require to be advanced at 4 per cent., and they would receive the money from time to time as it was wanted, so that a large sum would not be lying idle. As to the conversion of the

Digitized by Google

debentures, it was not possible to do anything until the term of the debentures expired. That would be in 1900, and they had no doubt that they would then be able to pay them off and get any money they wanted for much less than 5 per cent. The percentage of cost of generation and distribution to revenue in 1894 was 50 per cent., but in the past year it was reduced to 45 per cent The information asked for was published every week.

The resolution was then carried unanimously, as was one for the reappointment of the retiring directors, and the meeting concluded with the usual vote of thanks, special mention being made in the latter of Mr. Patchell, the engineer.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY, LIMITED.

The ninth ordinary general meeting was held on February 20 at 1, Great George-street, Westminster, Mr. Granville R. Ryder presiding.

The **Chairman**, in moving the adoption of the report and accounts, said he thought they afforded evidence that there was plenty of vitality in the Company, and that its progress was steady and continuous. During the year their main mileage had been increased by a mile and a quarter, making a total of 20 miles. The houses and shops connected had increased from 908 to 1,109, the lamps supplied by the Company from 80,678 to 94,780, and the sale of electricity from 977,789 units to 1,228,734. The net profit had increased from £9,289 to £10,988. The debenture debt had been converted from 4½ per cent. first mortgage debentures to 4 per cent. debenture stock, the debentures being paid off at £105 by new stock issued to the holders. With part of the proceeds freehold premises close to the Company's central station at Knightsbridge had been acquired, which would be of very great advantage in connection with the working of the station. The total capital expenditure during the year was over £20,000, of which £7,350 was for engines, dynamos, and boilers. £1,351 for meters, £4,442 for mains, and £1,121 for batteries. The sum of £1,000 had been written off the goodwill account, and the renewal account had been strengthened by the addition of £4,270, making the total amount placed to that account £9,990

Mr. G. H. Hopkinson seconded the motion, and the report was adopted.

A final dividend at the rate of 7 per cent. was declared on the ordinary shares, making, with the interim dividend. 6 per cent for the year.

Messrs. G. R. Ryder and A S. Bolton were re-elected directors, and the auditors were also re-elected.

NOTTING HILL ELECTRIC LIGHTING COMPANY, LIMITED.

The annual general meeting of this Company was held on Tuesday at the Company's offices, Bulmer-place, Notting Hill-gate, Mr. Sidney Waters presiding.

The **Chairman**. in moving the adoption of the report and accounts, a copy of which was given in our last week's issue, first briefly referred to the absence of Mr Crookes (the chairman of the Company) in South Africa, and said that the resolution to be submitted would be also for the declaration of the dividend of 6 per cent. on the preference shares and 2 per cent. on the ordinary shares. Referring to the accounts, he remarked that it was a matter for congratulation that the future of the Company was regarded with such confidence that they had been able to issue their preference shares at a premium, and they had applied those premiums to the reduction of the preliminary expenses account. The new accumulator had been necessitated by the expanding business of the Company. It had been built by the side of the original one, and with connections had cost £1,818. Mains had cost £2,489, two-thirds of which sum was for laying the mains along Addison-road and extensions in the neighbourhood, and the balance was for small extensions. With regard to the contemplated second central station in the neighbourhood of Addison-road, it had neither appeared that the revenue likely to be derived from it would justify the outlay, nor was a suitable site to be obtained. Under the advice of their engineer (Mr. Schultz) the Board decided to supply the district from their central station, although it was more than a mile distant. This had been in every way a success. The concentration of work under one roof had proved economical, and the supply of current was perfectly satisfactory, while the demand had shown clearly that a second station, if it had been erected, could not have paid for years. In reference to the revenue account. there had been a satisfactory increase due to sale of current—182,327 units being sold, as against 130,266 in the previous year. The expenditure upon the accumulators had been charged to revenue instead of taken from the depreciation and renewal fund. The directors proposed to draw £400 for their fees, as against £300 in the previous year, in place of the £1,000 to which they were entitled. The depreciation fund stood at £1,300, and it was the policy of the Board to increase it to such an extent that the Company would be able to meet any accident or breakdown that might happen without inflicting on the shareholders a loss of their dividend. The only mischance that had happened to them during the year had been due to the water companies' pipes bursting during the great frost. This had caused the flooding of three of their culverts, but although there was necessarily a loss of a certain amount of current, he was pleased to say none of their customers were deprived of their light, and the Company had not failed to keep up the proper standard of pressure. In view of a similar occurrence in the future, additional drains had been put in. Considering their district, the business of the Company was increasing at a satisfactory rate, and it would be seen from the diagram prepared that though the current taken varied from month to month, each month showed an increase over the corresponding month of the previous year. This expansion would doubtless continue, but its rate would be dependent upon the improved prospects of finance, since when times were bad people avoided the outlay necessary for wiring their houses. There was a fair amount of new building in their district, and the use of electricity was also likely to increase for other purposes, such as for cooking, for advertisements, and, when adverse legislation was removed, for road carriages. As soon as their Bill was passed they would proceed energetically with their northern area, and an important part of the extensions would be the trunk line to be laid down Holland Park-avenue, which would complete the Addison road system, from the Uxbridge-road. The value of the current consumed per lamp, though higher than last year, was still less than that of other London companies; but it must be remembered that their district contained no clubs and theatres and buildings of that kind, and comparatively few shops. It followed that great caution must be exercised before deciding to reduce the price of their current. They had made many extensions which only just paid their way, and in the past year 81 new installations had required 23 extensions. They had, however, a scheme of rebates giving a slight reduction to those who burned their lamps for a greater number of hours, and in future they might consider the practicability of a further extension of that system. Their customers might rely upon it that, besides giving them a light which was perfectly steady, the Board would consider what could be done to reduce its cost at the earliest period that it was safe to do so. It might be added that, in view of fires which had occurred at central stations, the Board had effected an insurance on their revenue in case of such a disaster occurring. Their assessments had been increased, but they had been advised not to appeal.

Mr. E. Franklin seconded the resolution, remarking that there was one matter of a personal nature which the chairman had left to him to refer to, and that was that as a mere act of justice they should acknowledge the energy and exertions of their engineer, Mr. Schultz, whose spare time appeared to be occupied in working out schemes for the benefit of the Company. With reference to the office staff, when they were informed that out of a revenue of some thousands there was now left due only about £13, shareholders would see how their staff did their duty. It had not been customary to pass a formal vote of thanks, but he thought this acknowledgment was justified.

The retiring directors (Messrs. Waters and Crookes) and the auditors were then re-elected, and, in acknowledging his re-election, the **Chairman** said that, having watched over the Company from its infancy, he now began to feel proud of its progress. Its future seemed now to be thoroughly assured.

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY, LIMITED.

The annual general meeting of this Company was held last week at the Company's central station, Richmond-road, Kensington, Mr. W. Page presiding.

In moving the adoption of the report and accounts, a copy of which appeared in our last issue, the **Chairman** said the increase in the lights connected during the past year was equivalent to 8,304 8-c.p. lamps, bringing up the total number to 44,162. The revenue had gone up from £5,010 in 1890 to £15,394 in 1894, and it was still increasing. In the first six weeks of 1894 the applications for connection numbered 831, while during the same period of the current year there had been 1,420 applications. In 1892, 1893, and 1894, although the output was greatly increased, the expenditure was kept quite steady, but in the past year it had been larger. There were several causes for this which he anticipated would not occur again. During the last week or two, since they had to some extent modified their working arrangement and substituted new plant for that of an older type, a considerable saving had been effected in coal. Although theirs was an entirely residential district, he believed that when they got their number of lights sufficiently increased the undertaking would prove to be much more profitable than it was at present.

Mr. R. A. Germaine seconded the adoption of the report. The motion was carried, and was followed by a resolution for the payment of the remainder of the dividend on the 7 per cent. cumulative preference shares.

NATIONAL TELEPHONE COMPANY.

The seventeenth ordinary general meeting of the National Telephone Company, Limited, was held last week at the Cannon-street Hotel, E.C., Mr. J. Staats Forbes (the president of the Company) in the chair.

The **Chairman**, in moving the adoption of the report, said there had been during the half year a comparative increase of £43,680, or 11·55 per cent., in income, and in working expenses the increase was £11,344, or 5·52 per cent. The net result of the half-year was a profit of £167,873, or an increase of £29,230 on the corresponding half of last year. They were able to report progress in all directions. With reference to the dividend of 6 per cent., he stated that they must bear in mind that they had to face competitions and combinations. They had had to deal with the New Telephone Company and the Mutual Telephone Company, which were got up and run in order to be bought off, and therefore they thought

Digitized by Google

it prudent, after discounting the agitations against them, and taking into consideration the expansion and advantages of their business, to give the shareholders the benefit of an extra ½ per cent. dividend. The agreement with the Post Office with regard to trunk wires had been completed and the Company were now waiting to be paid. They hoped to be able to work amicably with the Postmaster General, to the interest of the public, and their own benefit, and they had no doubt that by hook or crook the trunk wire telephone business would increase enormously in its social and commercial value. The National Telephone Company must depend more or less on its universality. The amount they had to receive from the Treasury was considerable and equitable, but for the present it was not desirable to make the figures public. He did not propose to offer any criticism upon the competition which was talked about, and the fallacies which had been spread broadcast. Comparisons had been made as to what could be done in Stockholm; but it should be remembered that house-rent and all domestic expenses were on a very low scale there, and no doubt the charge for telephonic communication would be somewhat in proportion to the standard of values It was easy when they came to meet these suggestions by the dreadful process of reducing them to facts and figures to show how fallacious they were. Up to a comparatively recent period the telephone was an experiment, and for a number of years people would not take it seriously. Now, however, that was all changed. The Company had now 82,093 subscribers, and these people were coming in year by year at the rate of 8,000 or 9,000, so that the Company had to find large amounts of capital in order to take them on. The maximum charge was now £17, with reductions on every additional wire. The Company had spent £337,905 in the year 1895 in order to meet the demands of the 8,740 new subscribers, which worked out at an average of £38. 13s. 2d. The Company had been at work for a great number of years doing this sort of thing. In reference to the accounts, the most important item in the balance sheet was the reserve fund, made up of amount reserved from profits £279,545, and premium accounts, £36,804, or a total of £315,630 On the other hand, they had a large stock of materials, amounting to £204,853. He wished this item had been less; but if distributed in tools, wires and instruments all over the country it became comparatively insignificant. The Chairman concluded by referring in feeling terms to the loss sustained by the Company in the death of Sir Henry G. Calcraft, K.C.B.

The **Right Hon. Lord Harris** seconded the resolution, remarking that even public criticism was a good thing, for in the end it must come down to a matter of £ s. d. He found from the Government returns that the Post Office was carried on at a substantial profit, and surely the same privilege should not be denied to private persons who had ventured their money in such a magnificent service as the telephone service now was.

The resolution was carried unanimously, and on the motion of **Mr. Chapman**, seconded by **Mr. Seward**, a vote of thanks was passed to the chairman, directors, and officers of the Company.

NATIONAL ELECTRIC SUPPLY COMPANY, LIMITED.

The annual meeting of shareholders of this Company was held at 119A, Fishergate, Preston, on Wednesday. There were present Mr. E. H. Booth, J.P. (chairman), Mr. H. Curwen, Mr. J. Booth, and Mr. W. Brown (directors), and a fair number of shareholders.

The **Chairman**, in moving the adoption of the report and accounts, said in 1893 their total income was £3,345, and their total expenditure £4,354, showing a loss of £1 009 for the year; in 1894 their total income was £4,778, and the total expenditure £3,783, showing a profit of £995, and a reduction of expenses £571. Their income last year was £5,739, and expenditure £3,338, showing a profit of £2,401, and a reduction of expenses over 1893 of no less a sum than £1,016. The Corporation were beginning to appreciate the light, and had decided to light most of the public thoroughfares and streets, and also had in contemplation the lighting of all their public buildings. The churches also were taking it.

Mr. E. Pyke seconded the motion, which was carried unanimously.

Mr. J. Booth was re-elected a director, and the auditors were also appointed.

BRITISH ELECTRIC TRACTION (PIONEER) COMPANY, LIMITED.

The general meeting of this Company was held last week at Winchester House, E.C., Sir Charles Rivers Wilson presiding.

The **Chairman** stated that no resolution had to be submitted. The capital of the Company was £100,000, and 5 000 shares were offered to the public, who responded so readily that the amount asked for was subscribed many times over. The directors had been actively employed in pursuing the objects of the Company. They were at present promoting a Bill in Parliament for constructing electric tramways from Kidderminster to Stourport, a distance of 3½ miles. This would involve an expenditure of about £30,000 or £40,000. They were also promoting a provisional order for the construction of electric tramways from Oldham to Ashton and Hyde a very important route passing through a thickly-populated district in the neighbourhood of Manchester. They had several other important negotiations connected with a variety of localities, but for various reasons it would be undesirable to allude to them further on that occasion. With regard to the question of the system of electric traction which was likely to be introduced and to become the system of the future, they believed they had acquired the right to a system which partook of the nature of the open-conduit system, and which would be unattended by any of the inconveniences to which he had referred. It would also be extremely economical. They were greatly indebted to their colleague, Mr. Garcke (the managing director).

CENTRAL LONDON RAILWAY COMPANY.

The first report of the directors states that £506,420 has been received on account of shares, and that the amount expended was £168,285, leaving a balance in hand of £338 135. The engineers have been engaged in negotiations with the local authorities respecting the details of the stations and other works. and the contractors—the Electric Traction Company, Limited—have proceeded, as far as possible, with the acquisition of the necessary land for the station sites. and a commencement will shortly be made wi h the actual construction of the railway. An arrangement has been come to with the Waterloo and City Railway Company, whereby, in consideration of a contribution by them to the cost of construction, and afterwards of maintenance, they will have access by a subway from their City terminus to the system of public subways to be constructed by the Central London Company in connection with their central City station. This arrangement will facilitate the exchange of passengers between the two companies The Board of Trade has given the necessary certificate relative to the payment of interest during the construction of the line The passing of a formal resolution at an extraordinary general meeting to follow the ordinary meeting sanctioning the issue of the capital authorised by the Act of 1892 will not involve any increase in the amount of the capital offered for subscription in June last. From the accounts it appears that the mileage authorised is 6 miles 34 chains, no part of which is yet constructed Of the expenditure stated above, £115,000 was under the construction contract, directors' fees absorbed £1,800 and interest on the paid up capital at 3 per cent. £7,300.

The first half yearly meeting of the Company was held on Thursday at the Cannon street Hotel, under the presidency of Mr. Henry Tennant.

The **Chairman**, in moving the adoption of the report said he had no doubt that they would remember their line commenced at the Liverpool street Station and ended at Shepherd's Bush, running by the Bank and under Oxford street to its destination. It was to be constructed by means of two separate tunnels from end to end, and when completed they would be adequately lighted. There were to be 14 stations. The shareholders would also remember this other interesting fact—that the railway was to be worked by means of electricity. A contract was entered into with the Electric Traction Company and by this contract that company were to deliver over the railway and all its adjuncts in a complete state. The accounts presented showed that £506,420 had been received on account of the shares issued, and there had been spent £168,265. The principal item of expenditure, £115,026, was entered under the head of payments on account of the contractors. The unissued shares had been subscribed for under agreement by the Electric Traction Company, who had become liable for them to this Company. The unissued shares he referred to amounted to £682,470 of the total share capital of £2,850,000. The further expenditure on capital account was roughly estimated at £3 380,000 and this, added to the expenditure already incurred, brought the figure up to about £3 550,000. The authorised capital powers amounted to nearly £3,800,000, so they had a margin of about £200,000 left for contingencies. although he did not think any were likely to arise. As regarded the Mansion House station and subways—a work of great magnitude and intricate character—the plans had been approved by the City authorities, and the contractors would before long make a commencement at that point. He might also say that tenders had been invited by the Electric Traction Company for the construction of the tunnel for nearly the whole of the line. Those who undertook to execute these works would have to begin their operations on the sites of properties which would be taken down and afterwards replaced by stations. Another meeting of shareholders would be held in about six months' time, and they would then probably be informed from the chair that during those six months the work of construction had been set going very nearly from one end of the line to the other. At one time it was thought that there might be some difficulty in arranging with the Great Eastern Railway Company for establishing communication between Liverpool street Station and the station of the Central London Railway at that point, but he believed all difficulties had been removed. The Waterloo and City Railway, whose terminus was at the end of Queen Victoria street, had also entered into an arrangement for using the subways at the Mansion House which this Company had to construct. The engineers stated that their more detailed studies had only confirmed their opinion that no physical difficulties would be encountered in the construction of the line.

Lord Colville seconded the motion.

The **Chairman**, in reply to Mr. Griffith, said none of the directors of the Central London were directors of the Electric Traction Company, nor had they any financial interest whatever in that company.

The resolution was then agreed to.

At the special meeting which followed, the **Chairman** moved: "That the Board be authorised to raise £150,000 additional ordinary capital by the issue of 15,000 new shares of £10 each in pursuance of 55 and 56 Vict., cap. 241."

The **Hon. Mr. Mills** seconded the motion, which was adopted unanimously.

CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.

Directors: J. Irving Courtenay (chairman); Major-General Webber, C.B., retired R E (deputy-chairman); Nugent Danioll; Emile Garcke; G. N. Marten. Managing engineer: Frank King. Secretary: S J. Cluer.

Report of the directors (with abstract of accounts) to be presented to the shareholders at the annual ordinary general meeting of the Company to be held at the Central Station, 19, Cadogan-gardens, Chelsea, S.W., on Wednesday, May 4, at 12 noon:

During the year an issue has been made of £60 000 4½ per cent. debenture stock, which was fully subscribed. The balance of the ordinary shares authorised has also been allotted and fully paid up. The original 6 per cent. debentures (£36,900) have been redeemed. A Stock Exchange quotation has been granted for both the debenture stock and ordinary shares. The balance of the premiums on these issues, after deducting the expenses of issue (including the payment of the premium due on the redemption of the 6 per cent. debentures), amounts to £5,798. 8s. This balance has been dealt with in the net revenue account as under: amount placed to renewals and depreciation fund, £1,500; special law and incidental expenses written off, £3,251. 1s. 5d: amount placed to reserve fund, £1,047. 6s. 7d. The above item, £3,251. 1s. 5d, is special capital expenditure, and has been necessitated by legal proceedings in connection with the Cadogan-gardens generating station. The directors have decided to write off this amount out of the premiums, instead of spreading it over a number of years in a capital suspense account. The net revenue for the year (apart from the premiums) after payment of debenture interest (£3,143 16s. 3d.), is £6.414 16s. 5d. Of this, £900 has been paid as interim dividend at the rate of 6 per cent. per annum on the preference shares for the half-year to June 30, 1895, and the directors recommend that the balance of £5,514. 16s. 5d. shall be applied as under: dividend of 6 per cent. per annum on the preference shares for the half-year to December 31, 1895, £900; dividend of 5 per cent. per annum on the ordinary shares for the year 1895, £3,500; balance to be carried forward to next account, £1,114. 16s 5d. The price charged for current was reduced on July 1 from 8d. to 6d. per Board of Trade unit, a reduction of 25 per cent. The number of lamps supplied on December 31 1895, was 57,354, showing an addition of 10 068 during 1895, an increase of upwards of 50 per cent. on the number added in 1894. A considerable part of the capital expenditure has been incurred in extending the mains and enlarging the Cheyne-walk generating station in order to meet the increasing demand for current. An advantageous purchase has also been made of the freehold of a large plot of land around and including Cheyne-walk station in view of the necessity for providing increased accommodation for the Company's works. The retiring directors are Mr. Nugent Daniell and Mr. E. Garcke, who, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also offer themselves for re-election.

SCARBOROUGH ELECTRIC SUPPLY COMPANY, LIMITED.

The directors report that during the past year the Company continued to make satisfactory progress. There is a balance of £937. 9s. 8½d., which is more than twice the profit made in 1894. Adding the balance of £418. 12s 3d. carried forward from the previous year, there is £1,356 1s. 11½d. available for distribution. The directors recommend that this should be applied in paying a dividend of 2½ per cent., leaving a balance of £278. 12s. 11d. to be carried forward. Mr. J. E. Ellis, M.P., and Mr. Gilbert Wilkinson, the retiring directors, together with Mr. C. E Bradley, the auditor, offer themselves for re-election.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY, LIMITED.

The directors' report states that the accounts for the year show a net profit of £32,589. 14s. 1d., after charging the interest on the debentures. To this sum must be added £53,509. 18s. 5d. brought forward for last year, making a total of £86,099. 12s. 6d. From this amount is deducted the interim dividend of 5 per cent., paid July 23, 1895, amounting to £22,410, leaving £63,689. 12s. 6d. to be dealt with. Of this sum the directors propose to distribute a dividend of £1. 4s. per share, absorbing £44,820, being at the rate of 10 per cent., and making, with the amount already paid, a total dividend for the year of £1. 16s. per share, or 15 per cent, free of income tax, leaving £18,869. 12s. 6d. to be carried forward to the next account. Various lengths of telegraph cables have been manufactured for different cable companies, and for foreign and Colonial Governments, including 705 knots for the Government of Japan. It is added that repairs of the Greetseil-Valentia and Hoyer-Arendal cables have been successfully carried out for the German Government.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY, LIMITED.

Directors: Alexander Bruce, J.P. (chairman), Ballaquayle Villa, Douglas; Frederick George Callow, advocate, Ballacurrie, Onchan, Douglas; John Allen Mylrea, M.H.K., J.P., Derby-terrace, Douglas; Alfred Jones Lusty, Goldhurst-mansions, London; William Parke J. Pittar, The Cliffe, Douglas; Richard Farrell, LL.D., Hazelmere, Douglas. Manager: J. Aldworth. Secretary: W. E Young.

Report of directors and statement of accounts for the year ending December 31, 1895:

Including the sum brought forward from last year, the available profit, after providing for debenture interest, amounts to £13,240. 1s. 6d. Out of this sum, interim dividends on the preference and ordinary shares for the first six months of the year, at the rate of 6 per cent. and 7½ per cent. per annum respectively, amounting to £4,312. 10s., have already been paid; and the directors now recommend that a further dividend for the remainder of the year, at the rate of 6 per cent. per annum on the preference shares and 8½ per cent. per annum on the ordinary shares, amounting to £4,687. 10s., be declared payable on March 6, 1896; that the sum of £2,000 be added to the reserve and renewal fund, and that the balance of £2 240. 1s. 6d be carried to profit and loss new account for current year. The directors have to report that the traffic upon the electric line has been very satisfactory; so much so that, in addition to the four new motor cars and one saloon car constructed and used during last season, the directors contemplate ordering more cars to cope with the enormous and growing traffic. The permanent way has been extended to the centre of Laxey during the past year, and arrangements have been made for a

Digitized by Google

much more convenient station. Several waiting-rooms have also been erected at convenient places along the route The directors have arranged for the purchase of a portion of the Derby Castle grounds, at the junction of the electric and horse car lines together with two houses adjoining, upon which it is proposed to erect a suitable station, depôt, and offices, and so concentrate the working of the different lines. This will enable the directors to dispose of other valuable property not so conveniently situated. The directors have also to report that during the past year, after considerable negotiations, arrangements have been made, and agreements entered into, with the Douglas Town Commissioners, by which this Company has secured a further 21 years' lease (from 1897) of the Douglas Bay line, also power to double the entire line and to construct and work a cable tramline to Upper Douglas, which has now been commenced. These agreements have been confirmed by Act of Tynwald, full particulars of which have already been sent to the shareholders. The work of construction has been entrusted to the eminent firm of Messrs. Dick, Kerr, and Co. Limited. Preliminary arrangements have also been made for the purchase of the Snaefell Mountain Railway, which, it is considered, will prove highly advantageous to the Company, and the approval and sanction of the shareholders thereto will be asked at the extraordinary meeting. It is proposed to raise the cash required for the construction of the Upper Town tramway and the purchase of the Snaefell Mountain Railway by the issue of debenture stock The shareholders will further be asked to pass resolutions altering certain parts of the articles of association of the Company, which the directors are advised would be desirable in the interests of the Company, the particulars of which have been already forwarded to the shareholders. The whole of the plant, rolling-stock, permanent way, buildings, etc, have been added to and maintained in an efficient manner during the year. The retiring directors this year are W. P. J. Pittar and Richard Farrell, LL.D., both of whom are eligible and offer themselves for re-election. The auditors, Messrs. Aldred, Astbury, Turner, and Co., also retire, and offer themselves for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Naples—Tenders are wanted by March 9 for 3,500 kilogrammes of copper wire The estimate is 6,475 lire. Address, La Fonderia reale, Napoli.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, Avenue Hache 8, Paris.

Droylsden.—Tenders are required for the supply of dynamo, accumulators and all necessary for 20-light installation. Box 12, Post Office, Droylsden.

Namur.—Tenders will be received on July 10 next for the construction of a telephone building at Namur. Plans and particulars can be obtained from le Service Téléphonique, Namur.

Leeds.—Firms desiring to tender for the various works required in extension of the electric light station in Leeds, should send their names to Messrs. Milnes and France, architects, 99, Swan-arcade, Bradford.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of apparatus for electric alarm bells. Tenders, suitably endorsed, must be sent to the Chief Engineer, at the Company's Stores, Santa Apolonia, Lisbon, by March 11, and particulars, etc., can be obtained from the Paris Offices of the Company, at 28, Rue de Châteaudun.

Christiania.—Tenders are wanted for the supply of telegraphic instruments, including 26 Morse apparatus, 11 galvanometers, and three signal bells, paper tape, etc., for the Norwegian State Railways. Tenders must be sent in by March 11 to the office, Iernbanctorvet 8 9, and particulars can be obtained of the Inspector of Telegraphs, Ostbalnistation, Christiania.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange-town, Yorkshire, to whom the plans, etc., must be sent by May 1.

London, S.W.—The Guardians of Chelsea invite tenders for the supply and fixing of telephones and communications with certain wards and rooms of their infirmary in Cale street, in accordance with a specification which may be obtained, and samples of the instruments and fittings which may be seen, at their offices, 250, King's-road, Chelsea. Tenders must be delivered at the Guardians' offices by noon on March 10.

Paris.—The Direction générale des postes et des télégraphes, rue de Grenelle 103, Paris, require tenders for the supply of 10-millimetre and 16-millimetre paper tape for telegraphic instruments. Application for permission to tender must be made to the Direction by March 14, and tenders sent in by March 24. Tenders are also wanted for nine lots of apparatus for telegraphic offices. In this case application must be made by March 15, and tenders sent by March 25.

Herne (Germany).—It is proposed to make a street railway nine kilometres (5½ miles) long from Herne to Recklinghausen, to be worked either by gas motors or electric traction. The undertaking will be put out to general competition, and the contractor will have to covenant for its completion in from one to five years. Tenders must be sent in by March 18, and particulars, price 1 mark (1s.), can be obtained from Herr Amtmann Schaefer, Der Verwaltungsausschuss Herne.

Keighley.—Tenders are invited for providing and fixing telephonic communication between the various buildings forming the infectious hospital now in course of erection at Morton Banks, near Keighley, for the Keighley and Bingley Joint Hospital Board. The buildings and plans can be inspected on application to Mr. Alfred Moore, clerk of the works at the hospital. Tenders, marked on the outside "Tender for Hospital Telephones," will be received by Mr. Geo. E. Spencer, clerk, North-street, Keighley, not later than noon on March 4.

Hanover.—Tenders are wanted for the supply to the State Railways during the ensuing year of certain articles for the telegraphic service of the districts of Altona, Cassel, Erfurt, Hanover, and Münster. The contract includes 250 lamp globes, 40,000 lamp chimneys 38,600 zincs and 22 500 coppers for galvanic batteries, 40,900 kilogrammes sulphate of copper, 5,040 kilogrammes sulphate of zinc, 159,700 rolls of paper-tape, etc. Conditions and particulars can be obtained from the Rechnungsbureau, Königliche Eisenbahn Direktion, Joachimstrasse, Hannover.

Chesterton (Cambs).—The Urban District Council is open to receive tenders for the public lighting of the district for seven years. The tenders shall be made in the three following modes—namely, (*a*) lighting the district from August 14 to May 15 (inclusive) in each year; (*b*) lighting the district throughout the whole year commencing May 15 next; (*c*) lighting the district for either of the above periods (1) with ordinary burners, (2) with incandescent burners, if the illuminant with which the tender be made be gas. All cleaning, lighting, and maintenance to be done by the contractors. Tenders to be sent to Mr. James Spearing, clerk, 15, Sydney-street, Cambridge, by March 31.

Digitized by Google

Sunderland.—The Corporation want tenders for the following plant required at the electric supply station: (*a*) two steam-engines and continuous-current dynamos, with steam and exhaust pipes and switchboard extensions; (*b*) two water-tube boilers of Babcock and Wilcox type; (*c*) fuel economiser; (*d*) a water-softening plant; (*e*) a cast iron tank. Specifications, general conditions, and form of tender can be had at the office of the borough electrical engineer, electric supply station, Sunderland, on payment of a deposit of £1. 1s for each of the above. The deposit will be refunded on the receipt of a bona fide tender. The tenders will be let subject to the consent of the Local Government Board to the application of the borough of Sunderland for the extended loan for the above works. Tenders to be delivered at the office of Mr. Fras M. Bowey, town clerk, Town Hall, Sunderland, by 5 p.m. on March 13, addressed to the Chairman of the Highways Committee, and endorsed "Tender for Extension of Electric Supply Station."

Bangor.—The Corporation invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough. The contract will be split up into two sections: (1) construction, supply, and erection of boilers (water-tube), steam-engines (double acting), steam and exhaust pipes, etc., economiser, feed pumps, condenser, alternators, exciters, accumulators, switchboard, travelling crane; (2) supply and laying down of mains and transformers. Specifications and plans may be obtained on payment of £2 2s. for the former and £1. 1s. for the latter, which will not be returned, at the office of Mr. F. Hastings Medhurst, M.I.E E., Westminster-chambers, 13, Victoria-street, S.W., on and after 24th inst. The firm whose tender is accepted will be required to enter into a contract and a bond with two approved sureties for the due performance of the contract. Firms may tender for one or both sections, but tenders for a part only of either section will not receive consideration. Sealed tenders, endorsed "Electricity," to be delivered at the office of Mr. W. H. Pritchard, town clerk, Bangor, by March 18.

BUSINESS NOTES.

Deal.—The present gas-lighting arrangements are causing much dissatisfaction, and correspondence in the local Press shows a decided leaning towards the adoption of electric light.

Harrow.—The work of laying the electric light mains by the Harrow Electric Light and Power Company is in hand and the erection of the electric light station in West-street is progressing.

Shoreditch.—The Vestry have decided to borrow £31,381 for the purpose of electric lighting works. These include a dust destructor, chimney shaft, ironwork for dust destructor, and electricity supply.

Brixton.—Mr. John Fyfe, the founder of the Electric-avenue, has been entertained at a complimentary banquet at Holborn Restaurant. The chair was taken by the Hon. Evelyn Hubbard, M P. for the division.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending February 23 amounted to £1,059, as compared with £847 in the corresponding week of the previous year, being an increase of £212

Appointment Open.—The appointment is open of professor of mechanics and mathematics at the Royal College of Science. Candidates should communicate with the Secretary, Science and Art Department South Kensington, S.W.

Bolton.—The borough surveyor (Mr. W. H Brockbank) and the electrical engineer (Mr. J. H. Rider, M I.E E.) have visited Dublin in order to inspect the Southern District Tramways Company's system, which has just been completed between Dublin and Dalkey.

Northern Society of Electrical Engineers.—The adjourned discussion on Mr. Robert Hammond's paper on the "Parallelling of Alternators," read by him before the society on 10th inst. at Manchester, will now take place on Monday, March 9, instead of Monday, March 2.

Moss Side (Lancs.).—At the Urban District Council meeting, the clerk read a communication from Messrs. Collier-Marr in which they stated that the Board of Trade had informed them that unless the electric lighting order previously granted was proceeded with, the Board would revoke it.

Cardiff.—The members of the Property and Markets Committee have inspected the new lighting of the central market by electricity, and decided to make certain recommendations to the Council, including further light inside the shops and also the electric lighting of the Old-arcade.

W. T. Henley's Telegraph Works.—The directors of W. T. Henley's Telegraph Works Company, Limited, propose subject to audit, paying a dividend of 5 per cent upon the ordinary shares for the year ending December 31, making, with the 3 per cent. already paid, a total of 8 per cent. for the year.

Newcastle-on-Tyne.—The proposal of the Corporation to acquire the tramways has been rejected by the ratepayers by a small majority. The Bill will therefore be dropped, and the question of the mode of traction to be adopted drops also. A very large proportion of the voting papers were returned blank.

Huddersfield.—Amongst the applications which have been made to the Board of Trade with a view to being embodied in provisional order Bills for consideration during the present session of Parliament is the Huddersfield electric lighting order, to authorise the Corporation to supply electricity in the town and to spend £24,000

Acton.—At the meeting of the District Council the Works Committee recommended that Mr. Goddard's application with reference to lighting Mr. Cohen's estate by electricity be refused. The clerk having suggested for consideration some legal points, it was resolved, after a brief discussion, to defer a decision till the next meeting.

Burton.—At a special meeting of the Town Council held for the purpose of passing formal resolutions dealing with the erection and issue of new 3 per cent stock, the Mayor (Councillor Morris) said the electric light was costing between £1 700 and £1,800 a year, but it was in its infancy, and year by year the deficit should become smaller.

City and South London Railway.—The returns for the week ended February 23 were £968, compared with £949 for the corresponding period of last year, being an increase of £19. The total receipts for the half year terminating as above were £7,914, compared with £7,988 in the same period of the preceding year, being a decrease of £74

Brighton.—A complete installation of the electric light has been carried out at the Turkish baths by Messrs. Clifford Hawkes and Walton, of East-street. In the House of Commons on Tuesday, the Brighton and Rottingdean Seashore Electric Tramroad Bill was introduced by the borough members, Mr. Gerald Loder and Mr. Bruce Wentworth.

Cuckfield (Sussex).—At a meeting of the Board of Guardians the clerk submitted specification for providing and fixing telephonic communication in the workhouse, etc., and it was resolved that the tender of the Private Wire and Telephone Company be accepted subject to their undertaking to keep the works in good working order for six months.

Macclesfield.—The Health Committee have received a letter from Mr. Radford which recommended that the electric light should be introduced on the farm buildings at Butley, at a cost of about £170 He had estimated for a supply of lamps, but thought the electric light would be the best in the long run. The subject was left over for consideration at the next meeting.

Torquay.—The Town Council have decided to apply for leave to borrow £22,300 for lighting the borough with electricity. A private meeting of opponents of the electric lighting scheme has been held for the purpose of considering what steps shall be taken to prevent the expenditure of ratepayers' money in the matter. It was decided to call a public meeting on the subject.

Eccles.—A special meeting of the Town Council has been held for the purpose of considering the advisability of appointing a deputation to the Board of Trade and Local Government Board for the purpose of applying for an extension of time in regard to the electric lighting order. It was decided to wait till the enquiry into the application to borrow £20,000 had been held.

Electric Light Insurance and Maintenance Company, Limited. This Company has been registered, with a capital of £10,000 in £1 shares, for the purpose of entering into contracts and issuing policies of insurance for the maintenance in proper order of all electrical appliances, and to carry out contracts for electric lighting. The registered office is 120, Bishopsgate street, E.C.

Eston.—At the meeting of the Urban District Council the surveyor reported that, in reply to the advertisement which he had been instructed to have inserted, he had received offers from several electrical engineering firms to submit schemes for lighting the district with electricity. They asked for plans of the district, which he was busy preparing. The schemes had to be in by May 1.

Bath.—The representatives of the Urban Sanitary Authority and the electric light company have met at the offices of the Board of Trade and discussed the proposed purchase by the authority of the company's undertaking with Sir Courtenay Boyle and Major Cardew. It is stated that there was such a wide divergence between the views of the respective deputations that no provisional agreement was come to.

Safety Concentric Wiring Company.—This Company inform us that they have acquired the business hitherto carried on under the style of J. D. F. Andrews and Co., at 15, Marsham street, and temporarily at 34, Victoria-street, the Company having bought outright the whole of the goodwill, all the patents, stock-in-trade, fixtures, etc, and that Mr. J. D. F. Andrews has now no longer any connection of any kind with the firm or patents.

Limerick.—Water power is proposed to be used for electric light and power production and supply to the city of Limerick, the Shannon, of course, furnishing the energy. The actual force available on an average throughout the year, in the 15 miles from Killaloe to Limerick, according to careful calculations made by the late Sir R. Kane, amounts to nearly 34,000 h.p. Winter time, with its greater need for artificial light, brings a corresponding increase in the volume of the Shannon's flow.

Bermondsey.—At a meeting of the Vestry Mr. Ball moved: "That a special committee of 18 members be appointed to consider and report upon the advisability of applying to the Board of Trade for a provisional order authorising the Vestry to supply electricity for public and private purposes within the parish, and as to the advisability of erecting a dust destructor in conjunction with the above works" Mr. Wells seconded and the motion was adopted, but the appointment of the committee was deferred.

King's Norton.—The House Committee having recommended the Guardians to make arrangements to light the new workhouse with the electric light, Mr. J. Botteley moved an amendment to

Digitized by Google

the effect that before taking any further steps in the matter the committee should consider and report upon the advisability of purchasing machinery and boilers powerful enough to light both the infirmary and the workhouse from the same plant. Mr. T. A. Bayliss seconded the amendment, which was carried.

Huddersfield.—At the meeting of the County Council the minutes of the Electric Lighting Committee, which were confirmed, set forth that the financial statement of the electric supply department for the year ending December 31 last showed a balance due to the revenue account of £1,373 4s. A resolution was accordingly passed requesting the Finance Committee to make provision for this deficit in their next rate. The sum of £2,500 had been ordered to be taken up on loan from the borough fund for capital expenditure.

Portsmouth.—The Electric Lighting Committee have decided to ask the Town Council to appoint a special committee, consisting of the chairman, vice-chairman, and five members of the Electric Lighting Committee, and a like number of the Roads and Works Committee, to consider the question of taking over the lines of the tramway company. It is suggested that the Corporation may, with profit to the town, adapt the lines for running cars by electricity, the tramway company paying rent to the Corporation for the use of the lines.

Inferior Lamps.—The Westminster Electric Supply Corporation, Limited, have called the attention of consumers "to the inferior quality of certain lamps, many of which are made in Germany. These give a brilliant light at first, but quickly deteriorate, causing complaints, which are entirely unfounded, that the pressure at which the Corporation is supplying is insufficient. The best makers have their names engraved on the glass, and by buying only lamps thus marked it is easy to avoid untrustworthy brands."

Belfast.—The Lord Mayor, accompanied by several members of the Municipality and the municipal engineer, have already visited Havre to examine the working of the electric tramways. They were received at the town hall by M. L. Brindean, deputy and mayor of Havre, with his principal officers, and M. Pupeteray, manager of the electric tramway company, who subsequently conducted the party over the works where the electricity is generated and the car depôts, and over the various tracks. The party also visited the docks, and subsequently left for Paris.

Kingston (Surrey).—The Electric Lighting Committee have reported that they had confirmed the acceptance by the chairman (Councillor Collings) of the offer of the Royal Exchange Insurance Company for the insurance of the electric works for £8,000, at a premium of 5s. per cent. Letters had been received stating that at present there was no probability of the barracks, the railway station, or the police station being lighted with electricity The Town Council decided to carry out the work of providing apparatus for charging electric launches at a cost of £150 10s

Edinburgh.—Augustine Church, George IV. Bridge has been wired for electric lighting, and the halls will be fitted up next week. The installation has been carried out by Messrs. Lowdon Bros., of Dundee. The Cleaning and Lighting Committee of the Town Council have considered a motion in favour of lighting by electricity all the remaining public thoroughfares in the city as defined by the tramway routes, and a motion as to the lighting by electricity of the West Port. On a division the committee resolved to recommend that no action should be taken in the matters referred to.

Dover.—The amount stated in the estimates of the Town Council for electric lighting is £950. At the quarterly meeting of the Finance Committee a conversation took place as to the charges for the use of the electric light in the town hall. The ordinary supply, it was stated was inclusive with the letting charge of the hall; but when the full lights were all on, there was an extra charge of 5s. per hour. The bills for ordinary and extra lighting were examined, and Mr. Councillor Brown, who initiated the discussion, said the charge appeared to be very satisfactory.

Holophane, Limited.—This Company has been registered by Messrs. Dixon, Watts, and Elkin, Savoy Mansions, Savoy, W.C., with a capital of £100 000 divided into 100,000 shares of £1 each, with the object of adopting an agreement made between O A. Mygatt and the Company for the acquisition of certain patents, patent rights, etc, relating to the construction of holophane glass globes, and the benefit in any country, except the United States of America and France, of all improvements in the patents, and to carry on business as manufactures and dealers in holophane glass globes and other globes.

Company Bills.—The report by the Board of Trade upon all the railway, canal, tramway gas, electric lighting, and water Bills and provisional orders deposited for the present session states that the total number of Bills deposited relating to railways, canals tramways, and the supply of gas, electricity and water is 157, as compared with 129 deposited for last session. The total amount of money proposed to be raised under these Bills is £41,009 183 as compared with £23,236,850, being an increase of £17.772 333 By the 53 Bills relating to gas electric lighting, and water undertakings, power is sought to raise £8 542,150, or more than £5,038 450 as compared with 1895.

London Extensions.—Notice having been given under the Electric Lighting Acts and orders by the Vestry of intention to lay mains across Camden-road and along a part of Kentish Town-road, the Highways Committee of the London County Council recommended that sanction should be given under certain conditions. Similar sanction was recommended to notices from the Metropolitan Electric Supply Company of intention to lay mains in various streets in the Edgware-road district; from the House-to-House Electric Light Supply Company to lay mains on the south side of Kensington-road, Oxford-street; and from the London Electric Supply Corporation to lay distributing mains in Park-street and Northop-street, Oxford street.

Dundee.—At a meeting of the Gas Committee of the Town Council it was stated that the patent for Dr. Hopkinson's three-wire system of electric lighting, which is in use in the city, expires in July next, having lasted 14 years. Dr. Hopkinson has sold his patent to the Westinghouse Company, and they have intimated their intention of applying for a 14 years' extension of the patent. A communication was read from the Glasgow Town Council asking the Dundee Council to join with them and other towns in opposing the granting of the application, the cost to be allocated in accordance with the quantity of wire used in the different towns. The Gas Committee agreed to recommend the Council to accede to the request of the Glasgow Town Council, and oppose the extension of the patent.

Bradford.—In reference to the question of electric propulsion on tramways, it will be remembered that the Corporation permitted an experiment which was rejected, in the overhead wire system on the portion of the line from Forster-square up Cheapside and into Manningham-lane. The advocates of electric traction maintain that the system was rejected without full and fair consideration Firstly, on the æsthetic side, they say that the overhead wires, when put up permanently, are not uglier or more of a nuisance than lamp-posts or telegraph poles; and, secondly, on the question of cost, they say that one element left out of sight is the great saving—50 per cent.—in wear and tear of the rails, which under steam traction has been found by the Corporation to be so important an element in the ultimate balance of profit and loss.

Sevenoaks.—At the meeting of the Urban Council, the Electric Lighting Committee reported that they had considered the letter from the secretary of the gas company, and they recommended that a contract be entered into with the company for a further period of three years from March 25 next. Councillor Hickmott suggested that the contract with the gas company should be for two years and not for three, seeing that there was a great probability of the electric light being introduced into the town. If the electric light be obtained at as cheap a rate as the gas, he, for one, should certainly adopt the former. The clerk did not think there was any need to alter the contract from three to two years, seeing that the electric light promoters had not yet got their provisional order, and some time must elapse before such an order could now be obtained. The report was adopted.

Worcester.—A report having been read at the meeting of the Library Committee in which reference was made to the frequent breakage of electric lamps in the classrooms of the institute, the Chairman stated that these accidents were due to the cheap make of the lamps. Mr. Millington said that he thought that the committee were quite satisfied that the cause of the breakage was the cheap quality of the lamps, and not, as had been suggested, the variation in the current. He suggested that that committee should authorise the sub-committee to provide better lamps for one room, and if those went the same way as the others, they would be prepared to do anything else in reason to remedy the defect. He, therefore, moved that the order for £17 worth of the old lamps be rescinded, and that Brush lamps be ordered for trial in one room. Mr. Joseland seconded, and the motion was carried.

Felixstowe.—At a meeting of the Urban Council, the clerk Mr. F. B. Jennings) read a letter from the gas company, stating that they could not light Ranelagh-road and other new thoroughfares as there were no mains within reasonable distance. Mr. Downing remarked that as the authority had expensive machinery at work the time had perhaps come when the Council should take some opinion as to the lighting of the place with electricity. They were paying £300 or £400 a year for lighting the streets, and yet the gas company did not seem inclined to go out of their way to light up certain roads because there were no mains sufficiently near. Mr. Hill considered the inhabitants had reason for complaint at there being two charges, one of 3s. to 3s. 6d. to those who used gas-engines, etc, and another of 5s. to private consumers. The question was referred to a committee for consideration.

Swansea.—The Corporation have been compelled by the action of the tramways company to withdraw the Bill before Parliament which would have enabled the town to have electric cars, electric light and a refuse destructor. The suggestion that an arrangement should be arrived at with the Mumbles Railway Company for the running of the latter's trains by electricity supplied from the Corporation generating station is now being considered by Sir John Jones Jenkins and his co-directors. The question for discussion is whether the expenditure necessary for the erection of an electricity station will now be justified. It is stated that Mr. J. C. Howells, of Llanelly, has written to the Corporation offering to purchase its provisional order. In order to protect the town against a monopoly, he is willing to enter into an agreement by which the Corporation can acquire the plant at intervals of seven years for net cost and a goodwill represented by the clear profits.

Central London Railway.—At the London Sheriffs' Court, Bloomsbury, before Mr. Under Sheriff Burchell and a special jury, the case of Ryalls' Trustees *v.* the Central London Railway Company has been heard. It was a claim by Messrs. Leonard Atkinson Ryalls, solicitor, Sheffield, and Hugh Hutton Stannus, 61, Larkhall-rise, Clapham, as trustees for Mr. Charles Wager Ryalls, 59, Haverstock-hill, barrister-at-law, the beneficial owner, against the Central London Railway, for the sum of £6,216, as

Digitized by Google

compensation for premises situated at 31, Holborn, required by the Company for the construction of a railway station. Mr. Littler, Q C, and Mr. Coward appeared for the claimants and Mr. G. M Freeman, Q.C. and Mr. E. Boile for the respondents. Mr James Green, surveyor to the Board of Trade and her Majesty's Board of Works, Major Isaacs, and Sir J. Whittaker Ellis gave evidence in support of the plaintiffs' claim, while witnesses called on behalf of the respondents put the value at £4,400, or at 25 years' purchase. Ultimately the jury found for a sum of £5,430.

Leeds.—The visit which the Highways Committee of the Corporation intended to pay to Bristol over a week ago, but which was unavoidably postponed, has now been completed. Most of the members of the committee—including the chairman (Mr. T. Hannam) the city engineer (Mr. T. Hewson), the manager of the tramways (Mr. W. Wharam), and the highway surveyor (Mr. T. A. Prince)—were present. After an inspection of the whole of the electric section, which is established on the overhead system, the committee proceeded to the power station, which is situate about midway on the route. The equipment of the station and of the whole line impressed them as being a complete mechanical success. The town clerk of Leeds (Mr. Harrison) has received a telegram from the parliamentary agents to the Corporation stating that it had been decided to dispense with the usual standing orders of the House of Commons in regard to the Leeds Tramways Bill. Accordingly the Bill will now proceed. The measure seeks to obtain power for the Corporation to provide for the working of the city tramways by electrical traction.

Hull.—A public meeting convened by the Mayor (Alderman Richardson) has been held for the purpose of considering the desirability of establishing electric communication with lightships and lighthouses. It was called in response to a requisition signed by 235 persons, but at the hour for commencing the proceedings at noon not more than half-a-dozen people were present. The Mayor explained that the requisition contained the names of such gentlemen as Mr. C H. Wilson, M.P., Mr. C. E. Lake (North-Eastern Railway Company), Alderman Toozes, and other representative gentlemen, and he felt it his duty to convene the meeting, but as there was so small an attendance he did not think they would be justified in calling it a "town's meeting" and he had no option but to adjourn it *sine die*. The meeting was consequently adjourned. At a meeting of the Electric Lighting Committee the chairman said that they had a good many orders coming in, and by the end of the present year they would have overtaken all the capabilities of their present station. A proposal to extend the system was referred to sub committee. With regard to the proposed reduction in the charges for electric lighting, the engineer said he would not recommend any reduction to consumers at present.

Hammersmith.—The following report from the Electric Lighting Committee in regard to the proposed electric light works was read at the Vestry meeting: "That having further considered the Clause 2 of our last report referred back to us by the Vestry at the last meeting we now recommend that when the surplus soil, for the excavation and removal of which the Vestry accepted Mr. Greenham's tender, has been removed the Vestry do proceed to excavate the sand and ballast, this work to be done by piecework. The sand so excavated to be used for the Vestry's general purposes, and the ballast retained for the concrete foundations" The recommendation was agreed to. The committee further reported: "That so soon as a definite plan and scheme has been approved and adopted by the Vestry, we recommend the Vestry to proceed, with its own workmen, to put in the whole of the concrete foundations for the plant and buildings, under the supervision of the surveyor, and at an estimated cost of 12s. per cubic yard, or £425." Mr. Bendon moved that this clause of the report be referred back to the committee, on the ground that the Vestry ought not to pledge itself to spend 12s. a yard upon the work when it could be done by piecework at 9s. per yard. Mr. Johnson seconded, and a long discussion upon the subject took place. Upon being put to the vote, the amendment was lost and the recommendation of the committee was then agreed to.

Dublin.—Mr. Wm. Anderson, secretary to the Dublin United Tramways Company, has written to the Lord Mayor pointing out that the decision of the committee in fixing a rent for which the assent of the Corporation would be given to the application of the Southern Tramways Company, who had made no offer, while ignoring his company's definite proposal, was come to without affording his company any opportunity of reconsidering their proposals. The directors had in consequence decided to make several proposals. They offered to pay the Corporation an annual rent of £8,000 per annum when authority to equip and work with electrical power the whole of the city tramways had been obtained, such mileage rent to commence to accrue for each line or section of tramways when the necessary authority for electric traction on such line is obtained. They undertook not to increase their present scale of fares and to construct necessary extensions, and they also undertook to convey the cars and traffic of the Southern Tramways Company into the centre of the city whenever they were permitted to erect an electric installation from Haddington-road, on terms to be settled by arbitration. The letter was read at the meeting of the Corporation, and deputations from the United Tramways Company, the Southern District Tramways Company, and the Dublin electric opposition also attended and addressed the meeting. The following resolution was unanimously adopted: "That the several letters from the Dublin United Tramways Company be referred to a committee of the whole house, and that the company be requested to make an offer as to the rental as well as the terms upon which they will extend the purchase provision of the Act of 1870 to all the existing lines over the system after the expiration of 14 years, and that the committee be authorised to confer with the company at its meeting if necessary."

The Tramways Union.—At the annual general meeting of thie Company on Tuesday, the Chairman (Mr. J. E. Walker), in moving the adoption of the report, said that in two out of the three cities which they supplied with means of conveyance, the future of the Company and their profits depended upon the introduction of electric traction. Not only did the present profits depend thereupon, but they had every reasonable hope that those profits would be very largely increased by the introduction of electric traction. By means of electric traction they could carry more people in one car, or two cars, the one being attached to the other. They could travel at an increased speed, and at those periods of the day when their largest requirements of traffic pressed upon them, they could carry large numbers of persons to and from particular points. It was impossible to do that with horses without keeping a very large and disproportionate staff, but with any mechanical power they could at a particular period of the 24 hours increase the application of that power, and thereby move a larger number of carriages and naturally carry an increased number of people At Bremen the matter was now under the consideration of the Senate or Town Council. With regard to Madrid, matters were very much in the same position, although they had not reached quite such an advanced stage; but in Spain, as elsewhere, the desire of the public seemed to be that electric traction should be introduced. The motion was unanimously passed.

Bristol.—At the half-yearly meeting of the Bristol Tramways and Carriage Company, Limited, the Chairman referred to the application being made by the company for an extension of the electric traction system, and expressed a hope that the Corporation would not persevere in their present course of imposing conditions which the company could not reasonably be expected to acquiesce in. Alderman Low seconded the motion, which was supported by Mr. Geo. White (managing director) and others, and carried unanimously. At the meeting of the Town Council the Town Clerk said a memorial had been received from the St. Paul's branch of the Labour Electoral Association suggesting that in any new powers granted to the tramways company the city should insist upon the employés of the company having an eight hours' day, that working-men's tickets should be issued for a double journey at a single fare, and that the necessary electric current should be supplied by the city. Alderman Cope-Proctor, in moving the adoption of the Electrical Committee's report with reference to the Bristol Tramways Order of 1896, said the tramways company had sought to obtain general powers to adopt the overhead electrical system but the committee thought it would be better that, whenever an extension was agreed upon, that particular extension should be brought before the Council. Another paragraph dealt with the specific extension now contemplated—from West-street to the Lebeck Inn, Stapleton-road, with an arrangement that next year the system in this direction should be extended to Fishponds The committee had gained from the company the concession for fares for workpeople between Old Market-street and Kingswood not to exceed 1d. Regarding the supply of electricity, the Corporation Electrical Committee were desirous that the power for propelling the cars be obtained from them; but for the moment they were willing to forego that condition in regard to the Stapleton-road section, and would consent to its being supplied from the company's own station. Councillor Hughes seconded the resolution, and it was carried. Councillor Pearson moved, "That the Sanitary Committee and the Electrical Committee be appointed a committee to consider and report upon the question of the introduction of the overhead trolley system of electric traction in the city, and if such a system should be sanctioned, then to report upon the terms upon which such sanction should be given." Mr. Alderman Proctor Baker seconded the motion, because he desired to see an immediate extension of the tramways to Fishponds. He was in favour of the extension of the electrical system to the whole of Bristol. The motion was carried.

North Staffordshire Tramways Company.—At the ordinary general meeting of this Company on Tuesday the chairman (Mr. W. J. Carruthers Wain) moved, "That the directors be requested to proceed with the pending negotiations with the various local authorities for the adoption of electricity as a motive power instead of steam and that the agreement between the British Electric Traction Pioneer Company and the Company dated January 8, 1896, be approved, and that the directors be and hereby are requested to carry the same into effect." He said the circumstances which had arisen in regard to the North Staffordshire Tramways were these: When under the usual statutory authority the Board of Trade inspector early last year inspected their lines with a view to a renewal of the permission to use steam power upon them, he found that a considerable amount of renewal of lines was necessary. He also discovered that there was a strong desire on the part of the inhabitants and on the part of the local authorities to replace the mode of force with which their line was at present worked by some other more attractive and more modern method. The Company had a limit of time given to them within which to renew the bulk of their line The desires of the inhabitants and of the local authorities went beyond the mere use of steam, and although they naturally desired the substitution of some better mode of traction it was left to the directors to propose a mode of traction. Consequently the question of electric traction, which had come so much to the front in England of late years had been considered. A company well known on account not only of the position it occupied but on account of the gentlemen connected with it, was

Digitized by Google

willing to enter into an agreement with them whereby they would find the amount of money necessary to relay the remainder of their line and to equip it from end to end electrically, which meant the expenditure of a very considerable amount of money—the provision of all the necessary generating plant and the supplementary station, the erection of posts and wires in the road, the bonding of the rails so as to ensure proper electrical continuity, and everything else inseparable from an electrically-worked line He was confident that from the moment the shareholders gave their approval the position of the ordinary shareholders would be very much improved and their security increased. Mr. Alderman E. J. Hammersley, in seconding the motion, said by adopting electricity they would get a more frequent service of cars and a cleaner and more effective form of traction, and in that way they would ensure the support of the public and the co-operation of the numerous local authorities in the district. The motion was carried unanimously.

Cork.—The electric tramway company have forwarded to the Board of Guardians a copy of a notice of application to be made to the Grand Jury for the sanction of a tramway scheme for the city and suburbs. As it was proposed to cross over one of the Guardians' sewers on the Victoria-road, they desired the consent of the Board. The matter has been referred to Mr. Coakley, engineer. At a meeting of the Public Works Committee a long report was read from the acting city engineer on the proposed scheme for providing electric tramways, in which, after describing the routes to be followed and the manner in which certain objections should be overcome, he said: "The promoters do not give any particulars in their notice as to the mode in which tramcars will be worked, whether by overhead or underground wires. When the former scheme was considered it was decided on your engineer's report, that a system of overhead wires should be adopted, carried at a sufficient height on ornamental cast or wrought iron posts or pillars. It was proposed to fix these posts about 20ft. apart at either side of the narrow streets and in the centre of the wide streets, and that the maximum potential of current through the head wires should be 500 volts. One great objection to these overhead wires is that in many places they are placed at such a low level as to prevent the passage of a fire-escape through the streets. Another objection is that the posts in some instances would obstruct the footways, and have an unsightly appearance. If these objections are got over, and if your committee should see their way to sanction the scheme, I see no objection to their doing so, provided the following conditions are agreed on: (*a*) the maximum potential of the current should be limited to 500 volts; (*b*) the wires should under no circumstances be fixed at a lesser height from the road way than 24ft; (*c*) the poles should be ornamental in structure, and of a design to be approved by your city engineer, and made of cast or wrought iron; (*d*) wall backets should be used in Cook-street instead of posts, provided the promoters obtain the consent of the owners of houses upon which the brackets may be fixed; (*e*) the position of the posts or poles should be subject to the approval of the city engineer; (*f*) the promoters should undertake to permit the Corporation in case they should at any future time undertake the lighting of the city by electricity. or any company who should undertake the public lighting by agreement with the Corporation, to use for that purpose any poles or brackets which may be erected by the tramway company; (*g*) that in case the company should go into liquidation the Corporation should become the owners of the permanent way. including setts and rails, and that same should not be disturbed or removed at any time without the express consent of the Corporation in writing. The promoters seek for power to construct the tramways to a gauge of 3ft., or such other gauge as the order may direct. In my opinion the 3ft. gauge is the most suitable, and wider should not be permitted. The notice accompanying the plans gives no particulars whatever of the size or section of rails to be used, and is most vague in its terms. Full particulars should be supplied before any formal assent is given to the scheme." The Chairman suggested that the report should be printed and circulated. Mr. Firmo asked if the promoters required a guarantee from the Corporation. The Secretary (Mr Giltinan) said they did not. It was only proposed that the order should enable the Corporation, if they could see their way to do so, to contribute towards the scheme, and enter into agreements with them as to the maintenance of the streets. Mr. M. O'Donnell said they should be very glad to get the ground for nothing. Mr. Firmo proposed that they approve of the engineer's report. The proposition was agreed to. It was also decided to leave the further consideration of the question over until the matter comes before the Council.

Wimbledon.—At a meeting of the District Council a memorial, signed by 160 North Wimbledon residents, was read in opposition to the electric lighting scheme. A deputation, headed by Dr. Wyld, also waited upon the Council and spoke in support of the statements contained in the memorial. The Chairman (Mr. A Holland), in reply, said the Council had given a great deal of attention to the electric lighting and incandescent gas lighting; they had consulted well-known authorities, and they thought they knew something about the merits of both systems of lighting. As regarded the incandescent gas light, there was no mystery about its brilliant illuminating powers. They saw it in the streets, and one of their reasons for not encouraging the gas company to make their so-called experiments was because they did not want them, knowing what the light was. It was in numerous buildings, and some in the open air, but they did not feel that it was for the benefit of the community to bolster up a monopoly of gas, and he hoped to show that Dr. Wyld was quite wrong in saying that incandescent gas was six times as cheap as the electric light. They did not consider it necessary to make a special appeal to the ratepayers when they were representatives of the ratepayers, and when, as was well known in all such cases of appeal, vested interests appeared They had seen that the gas company was working very hard against them although he did not insinuate that any gentlemen who had signed the memorial were interested in the gas company. If they increased the number of consumers they had to increase the cost, but he had a communication from a competent authority who was willing to carry out the whole of their scheme for £32 000. It had been proved over and over again that electricity at 6d. per unit was equal to gas at 3s. per thousand. Therefore electricity cost the same as gas, and not twice as much. The cost of incandescent gas, based on the present price of gas—3s. 8d. per thousand—was £3. 3s. 4d. per annum for each lamp, and that of a 32-c p. electric light, which an expert told him was equal to a 50-c.p. incandescent light, was £3. 11s. 4d. Mr. Bennett-Williams said it was the general opinion that the opposition to the electric light emanated from the Incandescent Gas Company, but there was not the slightest suspicion of that in connection with the deputation. They had only had one expert's opinion in favour of incandescent light as against electric light, and he would like to know if it was true that the cost of his coming to Wimbledon was defrayed by the incandescent light people. Dr. Wyld: Yes. Colonel Ross remarked that at Guildford the incandescent gas-lighting had been found very successful. At Kingston the cost of installing the electric light in private houses was £1 per light. The Chairman said the cost of installation depended on the fittings. It could easily be done for less than £1 per light in the case of simple suspension lamps. After a little further discussion the deputation withdrew. At a later stage the Chairman reported that Mr. Whitfield and himself recently attended at the Local Government Board offices and interviewed the head official there. They showed him the letter they had received from the Board of Trade with reference to the extension of their electric light license for a couple of years, and he stated that if the Council would write to him, enclosing a copy of the communication from the Board of Trade, he thought he could see his way to authorise the Council to take up a loan for the extended period next October the Council giving an undertaking to apply for a provisional order in the meantime On the granting of the provisional order the loan would be granted for 25 years on the usual terms Mr. Donaldson said he should be sorry to appear a "wobbler," but his opinion as to the advisability of introducing the electric light into Wimbledon had been a little shaken by the deputation. He would move that the Council give the gas company an opportunity of making their suggested experiments. Mr. Crickmay seconded. The motion only received the support of the mover and seconder, and was lost. The Chairman then moved that the steps suggested by the Local Government Board official he had referred to be taken by the Council. Mr Casswell seconded. and the motion was adopted with only two dissentients—Messrs. Crickmay and Donaldson.

Glasgow.—At a meeting of the Electric Lighting Sub-Committee reports were submitted by Mr. Foulis (gas manager) and Mr. Arnott (the electric engineer) bearing upon the position of matters as at present existing, and making suggestions with the view of improvement. The committee agreed to co operate with the Watching and Lighting Committee so far as street-lighting is concerned; but the whole system will be fully discussed by the joint committee on an early date, with a view to the adoption of the best method of lighting the whole municipality by electricity. The Tramway Committee of the Corporation have taken a further step in regard to motive power for the tramways. They have appointed Mr. Young (the manager), along with a member of the committee, to visit cities on the Continent where electric tramways are at work, and they have empowered the deputation to make a report embodying such information as might prove valuable when the Corporation as a body comes to discuss the adoption of some new motive power for working the tramways in the city The minutes of the Committee on Electric Lighting, which were considered at the meeting of the Corporation contained a recommendation that the Waterloo-street station should be extended and provided with additional plant at a cost of £6 000. The minutes of the special sub-committee contained the following report by Messrs. W. Foulis and W. Arnot: "We have carefully considered the saving that might be effected by transferring the arc lighting from John-street to Waterloo street, and supplying the lamps from the low-tension mains at present used for private lighting. This transference would necessitate new lamps being procured, as the present lamps are unsuitable for continuous low-tension current. The cost of the lamps, with the necessary connections, they estimated at £1,300. From the higher efficiency of the plant at Waterloo-street, as compared with that at John-street, and also from the fact that the additional current may be generated without extra cost for labour. the saving to be effected they estimated as follows: reduction in cost of fuel, £257; reduction of wages, £431; making a total of £688. Additional capital would be required for plant at Waterloo-street. but the sum that would probably be realised from the sale of the building and plant at John-street would meet this expense. The sum above mentioned was equal to £6 10s 4d. per lamp, reducing the cost per lamp per annum to £22. 10s. 1d" The special sub-committee approved the report, and resolved to recommend that the supply of current required for the existing street arc lamps be transferred from John-street station to the station in Waterloo-street. The special sub-committee also resolved to recommend that, in addition to the remit to them referred to in the minute of 20th ult., it be remitted to them to consider and submit an exhaustive report as to the supply of electricity for

Digitized by Google

private and public lighting, or for motive power, within the entire municipal area, with power to the special sub-committee to take such action as they may deem expedient to enable them to submit such a report. Mr. R. M. Mitchell moved the approval of the minutes. Bailie Burt, in seconding the motion said that when the electric light was introduced in Glasgow it was started on an experimental basis, and the committee had gone as far as they were warranted. So far as the private lighting was concerned they put down 1,200 h.p. at the station. The first winter they added another 700 h.p., the second winter another 700 h.p., and they now proposed to add another 700 h.p. They had thus practically completed the scheme as originally sketched. So far as the station was concerned, they could go no further, and despite the fact that the Post Office, one of their best customers, had put in an installation of their own, he maintained that so far as the private supply was concerned the demand had gone up by leaps and bounds. As to the street-lighting, unfortunately at the time it was inaugurated electricians were not so well up in the matter as they were to-day, but so far as Glasgow was concerned he held they had not made a very great mistake In 1893-4 with a capital of £120,000, they had a deficit of £607. Last year the deficit was a little more, but that was accounted for by the constant changes, and that they were not in a position to get customers to take up the supply. Over and above that, he believed they would come out this year with a very fair surplus. After a lengthy discussion, the motion was carried by 27 votes to 13 With a view to enable them to arrive at a satisfactory rearrangement of the lighting of the principal thoroughfares of the city by electricity, the Joint Lighting Committee of Glasgow Corporation have resolved to discard a number of the present lamps at the west end of Sauciehall-street and substitute in their places, as an experiment, opaque circular globes, similar to those in use in Edinburgh. The ventilation of the "Kief," the new steamer just built by Messrs. J. and G. Thomson at Clydebank, is by means of electrically-driven fans.

PROVISIONAL PATENTS, 1896.

FEBRUARY 17.

3535. The automatic electric self-registering long-distance signalling apparatus. William Rowland Hugh Inglis, Frodingham, near Doncaster.

3550. Improvements in simultaneous telephony and telegraphy. Edward Wythe Smith and the New Phonopore Telephone Company, Limited, Faraday House, Charing Cross road, London.

3556. Improvements in telephone paper racks. John Francis Bullock, 64, High-street, Camden Town, London.

FEBRUARY 18.

3627. Improvements in telephones. William Henry Russell, George Ellsworth Russell, Francis Millard Neale, and Henry Connett, Prince's-chambers, Wolverhampton. (Complete specification.)

3628. A new or improved dynamo brush. Francis Edward Elmore, Knostrop Old Hall, Leeds.

3633. Improvements in and connected with electric alarms and indicators. Frederick George Thomas and John Thornton, 70, Market street, Manchester.

3658. Improvements in joints for the conduits of electric mains. George Schultz, 70, Palace-chambers, Westminster.

3682. An improvement in multiple-contact circular electric switches. Siemens Bros. and Co., Limited, and Zachary Harris Kingdon, 28, Southampton buildings, Chancery-lane, London. (Complete specification)

3690. Electromagnetic induction system of propulsion. Alpheus Carpenter Shuttleworth, 46, Lincoln's inn-fields, London. (Complete specification.)

3705. Improvements in dynamo-electric machines. Valerè Alfred Fynn, 47, Lincoln's inn-fields, London.

3712. Improvements in electric accumulators. F Mouterde Camille Chavant, and J. George 18, Buckingham-street, Strand, London.

FEBRUARY 19

3736. Improvements in electrical accumulators. Thomas Parke , Wednesfield-road, Wolverhampton.

3761. Eight-day and above electric alarm clocks. George Houlsby Skee, Coundon, Bishop Auckland.

3796. Improvements in electrically-driven machinery for cutting coal or other minerals. Claude William Atkinson, 1, Queen Victoria-street, London.

3809. Improvements in sockets and holders for incandescent electric lamps. John Francis Cleverton Snell, Arthur Henry Martin Francis, and Robert Spilsbury Jeffery Spilsbury, 70, Chancery-lane, London.

FEBRUARY 20.

3823. Improvements in electrical lamps. Louis Pohlmann Foster, Penny Bank-chambers, Halifax.

3841. Improvements in and in connection with arc lamps. Frank Michael Lewis, 30, Park-row, Leeds.

3842. Improvements in cranes, specially applicable to electrically-driven cranes. Henry Berry, 30, Park-row, Leeds. (Complete specification.)

3846. Improvements in electrical generators. Thomas Harden and Samuel Glover, Corporation Gas and Electricity Works, St. Helens.

3847. Apparatus for reversing the flow of electrical currents. Thomas Harden and Samuel Glover, Corporation Gas and Electricity Works, St. Helens.

3864. Electrical thermometers. Charles Dexter Barker, 30, Agate-road, Hammersmith London.

3908. Improvements in electrical dial-indicating and communicating apparatus. Arthur Edward Butcher, 53, Chancery-lane, London.

3910. An improved magnetic regulator for the carbons of arc lamps. Frederic Klostermann, 97, Newgate street, London

FEBRUARY 22.

4028. An improvement in the construction of ammeters and voltmeters. Thomas James Baker, 65, New-street, Erdington, Warwickshire.

4033. Improvements in diffusing and colouring the light from incandescent electric lamps. J A. Sinclair, 55, Rowan-road, Hammersmith London.

4069. An electric vaporiser for oil-engines. Ernest John Clubbe and Alfred William Southey, 53, Chancery-lane, London.

4082. Improvements in or connected with apparatus for electrically igniting miners' safety lamps. William Ackroyd and William Best, 33 Chancery-lane, London.

SPECIFICATIONS PUBLISHED

1895.

2064. Electric switches. Hopkinson.

2218. Counters for electric currents. Hummel.

3055. Electric steering apparatus. King.

4154. Electro-deposition. Cowper-Coles Galvanising Syndicate, Limited, and Cowper-Coles.

6177. Alternating-current dynamos. Esson

6545. Arc lamps. Davenport.

6657. Incandescence electric lampholders. Lyons and Bevis.

7458. Electrolysis for metallic salts. Kellner. (Second edition.)

13670. Electric incandescent lamps. Cooper.

24516. Voltaic batteries. Epstein.

NOTES.

Obituary.—The death, at the age of 91, of Mr. S. Edison, the father of Mr. T. A. Edison, is reported from Norwalk, Ohio.

Northern Society of Electrical Engineers.—We hope to give Mr. Robert Hammond's paper on "The Paralleling of Alternators" in our next issue.

Submarine Boat.—As accessory to a competition for a submarine torpedo boat, the French Ministry of War have offered prizes for designs of a motor suitable for such a vessel.

University College, Bristol.—Mr. B. H. Bedall has been lecturing to the University College Engineering Society on electric tramways. The lecture included some remarks on the subject of electric locomotives. A discussion followed.

Engineers in Parliament.—The members of the House of Commons who are also engineers—or at any rate, eight of them—have held a meeting and decided to co-operate for parliamentary purposes. So far as numbers go, it does not seem a very formidable group at present.

Institution of Civil Engineers.—Mr. W. H. Wheeler's paper on littoral drift in relation to river outfalls was read at the Institution of Civil Engineers on Tuesday last. Mr. Wheeler's point was that wind action was confined to a comparatively small depth and was variable, while the action of the tidal current was continuous, and was therefore the main factor to be considered.

New York Overhead Railroad.—It is stated that the officials of the Manhattan Elevated Railway have, after considerable investigation, concluded that a combined system of third rail and storage battery is best adapted to meet the requirements of their road; they have, therefore, decided to equip the Thirty-fourth-street branch on that principle. Should it prove a success, the application to the rest of their lines will follow.

Trees and Lightning.—Dr. Cl. Hess, of Frauenfeld, contributes to the *Elektrotechnische Zeitschrift* an article on "The Poplar Tree as a Lightning Conductor," and gives statistics showing how often various trees are struck. Unless one wants to choose a tree to stand under during a thunderstorm the matter seems of little practical utility, but the different liabilities of various trees to be struck by lightning are well known to countrymen.

Leeds Engineers.—A paper has been read by Mr. J. Clark Jefferson before the Leeds Association of Engineers on the subject of tram haulage. After discussing the local circumstances of the place, he came to the conclusion that the overhead electrical system was most suitable to many of the routes, but contended that it was not necessary to have one uniform system throughout, and was not inclined to abandon the cable on the Chapeltown route. A discussion followed.

Acetylene.—It is known that acetylene is an endothermic gas, and therefore the possibility of it exploding when detonated is a matter that requires determination. So far as the experiments communicated to the Paris Académie des Sciences at Paris by Mr. Maquenne go, it would seem that such an explosion, if it were brought about, would not travel in a tube. Mr. Maquenne's experiments were made with fulminate detonators, and mixed gases were used.

Theatrograph.—Mr. R. W. Paul's moving-picture apparatus was shown last Friday evening at the Royal Institution, and its manageable size and comparative simplicity was favourably remarked on. As a non-technical contemporary puts it, "the whole thing can be comfortably packed in an ordinary portmanteau, and is worked by hand much like a chaff-cutter." It is hoped to have something of the same sort, but on a much larger scale, ready for the forthcoming Earl's Court Exhibition.

Exhibitions.—Information has been received by the Foreign Office respecting the international exhibition to be held in Brussels in 1897. There are 14 sections, of which No. 7 is devoted to electricity, and special attention is to be given to traction. The Canadian International Exposition opens on May 25. Russia has already accepted the invitation of the French Government to take part in the Paris Exhibition of 1900, and is the first of the great European Powers to do so.

A Dangerous Lark.—This is the heading under which the *Daily Chronicle* considers it appropriate to record the fact that last Sunday someone left three cells of a galvanic battery on a doorstep in Leamington. This was undoubtedly a particularly stupid thing to do, but where the danger came in, whom the cells were to hurt, and how, is not stated. The police took expert advice and consulted an electrician, who said the cells "were alive with electricity." Probably that electrician was also a humorist.

Spain.—The *Revista Tecnológico Industrial* of Barcelona says that electric lighting is now being established in Burriana (Castellón). This is a continuous-current installation, driven by a 100 h.p. steam-engine. A similar station is being built at Estepa (Seville). It is proposed to erect a turbine of 280 h.p. at Los Fayos in Tarragona for electric lighting purposes; and the illumination of Palma by electric light seems likely to be speedily accomplished. This has already been done at Darunes, and a further extension is reported from Hervás.

City and Guilds Institute.—The Executive Committee of the City and Guilds of London Institute have awarded the second Salters' Company's Research Fellowship for the encouragement of higher research in chemistry in its relation to manufactures to Mr. Sidney Williamson, Ph.D., F.I.C., F.C.S., who was for two years a student at the City and Guilds Technical College, Finsbury, an subsequently for three years at the City and Guilds Centra Technical College. Dr. Williamson proposes to work on some questions bearing on foodstuffs generally.

Lightning.—The *Pacific Electrician* says that either California is experiencing a very unusual winter or the climate is changing. It seems that quite a number of electric plants in that State have been badly damaged by lightning during the past winter. Attention has naturally been directed to lightning arresters. Our contemporary says that a few years ago no one thought of providing against lightning on the Pacific Coast except in a few special localities. Probably these thunderstorms are the Californian equivalent of our English mild winter.

The Rede Lecturer.—Prof. J. J. Thomson, M.A., F.R.S., who has been elected this year's Rede lecturer, is 40 years of age, but his life has been already academically and scientifically an eminent one. In 1880 he graduated at Cambridge as second wrangler, was Smith's prizeman, and was Adams's prizeman in 1883. Since 1884 he has been professor of experimental physics at Cambridge. He is the author of a treatise "On the Motion of Vortex Rings" and on "The Application of Dynamics to Physics and Chemistry," and has done good work in connection with electrical units.

Electric Cranes.—On the occasion of the recent visit of the North-East Coast Institution of Engineers and

Digitized by Google

Shipbuilders to Wallsend a good deal of interest was taken in the electric cranes at Messrs. Swan and Hunter's yard. There are three of these—two under the roof of the yard and one on the outside. The two under the roof weigh 14 tons each, and run along at the rate of 200ft. per minute with a weight on their jibs of three tons each. The cantilever crane outside the roof weighs six tons and has a jib of 65ft. projection, reaching right across the adjacent berths. The entire structure is made of steel.

Institution of Electrical Engineers.—It has been arranged, by permission of Messrs. Siemens Bros. and Co., that a party of students shall visit their works at Charlton on Saturday, March 14. The train leaves Charing Cross Station at 10.20 a.m., Cannon-street 10.30, and London Bridge 10.33, and passengers should book to Charlton Junction. Students desirous of being of the party must write to the honorary secretary of the students' class, Mr. G. C. Allingham, Eldon House, Lyndhurst-road, Hampstead, N.W., as soon as possible, and those who do not hear from him to the contrary may assume that they can be included in the party.

Electric Ploughs.—Some time ago we noted the attempts being made in Germany to work out a system of electric transmission of power for steam ploughing purposes. During the winter further experiments have been made at Rostock, in which an alternating current of 2,000 volts from a central station was used and transmitted to the field 2¼ miles distant, where it was transformed down to 220 volts. Two electric motors were used. As much as 25 h.p. seems to have been required, but no details are obtainable. Unless there happens to be cheap water power available, this does not seem likely to compete with a good portable engine in the field.

The Higher Voltage.—Mr. Stewart has given, in the *Western Electrician*, his experience as to the installation of over 15 central stations in the North-West of the United States with 200-volt lamps, and says that most engineers there are now specifying that system exclusively. Careful experiments covering many months show that the danger from fire is less, as the danger is not from voltage but from current. The small fuses of the 220-volt system give way at the slightest approach of danger, and sockets spark less. With good workmanship such a system is safer than any other, and bad workmanship is going out of favour. It is furthermore stated that the life of most of the lamps is 1,500 hours or over. After this it need hardly be added that Mr. Stewart believes the 220-volt lamp has come to stay.

University College of South Wales.—A circular, signed by the principal, president, and registrar, deals with the objects and work of the Cardiff University College, in view of the endeavour which is now being made to raise funds for new college buildings. In reply to an application from the college authorities, the Lords Commissioners of the Treasury promised a grant of £20,000 towards the new buildings, provided a like amount is contributed from private sources; and the Drapers' Company of London have agreed to make a donation of £10,000 towards the same object, if the above-mentioned £20,000, to be collected locally to meet the Treasury grant, is contributed before the end of July next. Of this sum as much as £13,464 has been already promised, Lord Tredegar and Lord Windsor heading the subscription list with £2,500 apiece.

Nomenclature Again.—No more has been heard of the euphonious word electrosciography, but inventors desirous of immortalising themselves seem to find it much easier work to invent new names for the Röntgen ray pictures than to explain the nature of the process. Captain Abney's favourite is electrography. Our contemporary *Photography* wants the word to be Röntography. Our objection is that if Prof. Röntgen's name is to come into the word, it might as well be spelt properly. Another proposal is radiography. None of these seem particularly happy suggestions. Some, however, of the American electrical papers have taken to calling the prints "cathodograms." That is just the one thing that they are not. With the aid of a Greek lexicon it would be possible to go much better than any of these—if it were worth while. Other gems are "shadowgram" and "penetraliography."

A Paris Electric Tramway.—With the exception of a few tramcars run with accumulators, little has been done in the way of electric traction in Paris up to the present. The reason of this is that the city authorities have absolutely refused to permit the adoption of overhead-wire systems. A line, however, is now in course of construction on the underground system of Messrs. Claret and Vuilleumier, and is briefly described in *Cosmos*. This is a closed-conduit system, the current being taken from metal plates between the rails, which are brought into circuit as the car passes over them. A similar line has been tried successfully at Lyons. The Paris line is to run from the Place de la République to Romainville, a distance of seven kilometres (4¼ miles), of which more than half are within the city. A portion of the line is already laid, but the station for generating the current is not yet finished. A tension of 500 volts is to be used, and it is expected that the service will be a seven-minute one, the whole journey taking half-an-hour.

Municipal Telephones Association.—In reference to the recent town's meeting in Manchester which decided adversely to the proposition that the Manchester Corporation should establish a telephone exchange, a circular has been issued by the Municipal Telephones Association to the subscribers of the requisition for the meeting. The circular states that "the executive committee of this association have in their possession absolute proof that the meeting was packed by persons brought from towns outside Manchester who were not ratepayers in the city," and adds that "the committee are, of course, in no way influenced by a vote obtained in such an unscrupulous manner. They are now preparing a scheme which will shortly be submitted to the City Council for its approval; and inasmuch as no risk of loss to the ratepayers is involved, there is strong reason for believing that it will be approved." An appeal is further made for the support of telephone users. There has been a large amount of correspondence on the subject in the local Press.

Post Office Telegraphs.—A parliamentary return has been issued showing the gross amount received and the gross amount expended in respect of the telegraph service from the date of the transfer of the telegraphs to the State to March 31, 1895. The total receipts between 1870 and 1895 were £43,137,892. 7s. 6d., and the total expenditure (including £2,636,982. 2s. 3¼d., balance to meet interest on stock created on account of the telegraph service and the redemption of debt) was £43,967,675. 15s. 8¾d., leaving the balance of receipts over expenditure at £829,783. 8s. 2¾d. Another return for last year states the total receipts for 1895 at £2,646,413, and the expenditure at £2,788,051, a loss of £141,637 being thus shown. Whether this means that the Post Office ought to make no more extensions, or whether, on the other hand, extra facilities should not be given and everything done to attract more custom, or whether simply that, considering everything, including the invention of the telephone, the companies were exceedingly lucky in getting bought out by the Government, is a

Digitized by Google

matter that would take more space to deal with than can be given in this note.

Electricity and Vegetation.—Mr. G. Claude, writing in *L'Etincelle Electrique* on the influence of electric discharges on vegetation, gives a summary of what has been done by several investigators in this direction. In particular, he relates an old experiment of Mr. Spechnew, in which a network of wire furnished with arrangements to facilitate discharge was stretched over a field and kept at a high potential relative to the earth. The result was an increased growth, varying from 132 to 2 per cent. with the eight different kinds of crop experimented on. It is suggested that the explanation of the phenomenon is to be found in the formation of nitrates from the air under the influence of the discharge. The figures given, however, do not in any way support this view, since the increased growth is greatest on the part of clover, which it is now known can manufacture its own nitrates, and least on the part of wheat, which cannot, but which responds vigorously to an artificial supply of them.

Undue Heating.—The *Electrical Age* has obtained quite an anthology of opinions as to what is the meaning of "unduly heated" in the definition of the safe carrying capacity of a conductor. Prof. Crocker considers any heat which is bearable to the hand as perfectly harmless. In dynamos and motors the allowable rise is 40deg. to 45deg. C., as measured by a thermometer placed against the surface and covered with cloth; in wiring, the most usual standard of a safe current is the number of amperes which, if doubled, will not raise the temperature above 150deg. F. Mr. Edison thinks that the conductors should not heat more than 212deg. F. Mr. Wiener, after a certain amount of calculation, arrives at a final temperature of 140deg. F. Mr. Loomis defines "undue heating" as heating to a temperature which impairs the insulation. This is obviously wide of the mark. Mr. Dunn says for wire enclosed in mouldings it would mean, according to Edison regulations, a rise of more than 18deg. F.; for dynamos it means a rise greater than 81deg. F. Prof. Elihu Thomson will not define the term in degrees, but it is safe to say that when a wire is quite hot to the hand ordinary insulating materials are on the point of injury. The only safe rule is to use such a wire as will under a great variety of circumstances still remain within safe limits of temperature, and, fortunately, the use of such a size of wire is conducive to the best economy.

Electric Light in Surgery.—The application of Prof. Röntgen's radiations to the purpose of surgical examinations has been very generally taken up both in England and abroad, and with results which, as far as they go, are decidedly promising. The subject is, however, one that is interesting rather to the surgeon than to the electrical engineer. It must necessarily be some time before the experience and knowledge necessary for the successful manipulation of the Röntgen rays for this purpose can be acquired and spread among the medical profession. Meanwhile, it is interesting to note that Dr. Oakley, of Halifax, in a letter to the *Lancet*, has called attention to the fact that common light from an ordinary incandescent lamp can very frequently be used with advantage in surgical work. "I have used it," he says, "constantly during the last 10 years with very satisfactory results, both in the detection of foreign bodies and malformations in the hand, foot, nose, ear, and wherever, in fact, it is possible to render a part sufficiently translucent. I have frequently demonstrated this to friends, and also at the annual meeting of the Yorkshire branch of the British Medical Association held at the Halifax Infirmary four years ago. I do not think the use of the light in this manner is sufficiently well known. For ordinary work I use the small throat lamp, but for deep penetration a larger, placed in a small dark chamber, so that the whole of the light shall be concentrated on the part to be illuminated."

Rontgen's Radiations.—The Americans, who began by disbelieving in the new photography altogether, have now taken it up with avidity, and the technical Press is full of it. The American non-technical Press has also found it a convenient field for displaying its usual characteristics. Up to the present, however, little appears to have been done except to repeat the experiments made in Europe, and fully described. Another branch of work entered upon with much energy has been the looking up of old papers with reference to vacuum discharges, with a view of showing that somebody knew all about it a long time ago, only he did not take any photographs. That is a branch into which it is not intended to go here. So far as any real determination of the nature of the new radiations is concerned, little progress has been made. Their marked action on the electroscope is still being investigated, and it has been suggested that this supplies a readier means of indicating their presence than the tedious method of exposing a photographic plate. The results obtained have been to some extent discordant. This may possibly arise from the different tubes used giving radiations of different qualities, or, let it be said boldly, of different wave lengths, although up to the present there has been no proof of the existence of a wave either longitudinal or transverse. Some experiments of Prof. Righi may, however, have some bearing on this point. In this case a charged metallic disc was used having in front of it and very close a metallic network in electrical communication with the earth. On this apparatus ultra-violet light had a decided action, in so far as it tended to disperse a negative charge on the metal plate and originate a positive one, while the Röntgen rays discharged both positive and negative charges alike. If the vibration is longitudinal, it is almost certain that the transmission must be very rapid, and the wave, therefore, a comparatively long one. It might be worth while to ascertain if it could not be measured directly.

Units and Dimensions.—A paper read by Mr. T Proctor Hall before the Iowa Academy of Science on the subject of unit systems and dimensions is published in the *Electrical World*. Mr. T. Hall shows that the C.G.S. system is itself an arbitrary one, since the gramme depends upon the earth's attraction for water. He contends that a relation which by definition fixes the value of a unit should, if possible, apply to all quantities to be measured by that unit, and that the law of gravitation, which most nearly satisfies that condition, if chosen as a base, enables a system to be constructed having only two fundamental units—the second and the centimetre. In this case, mass is eliminated for the reason that as unit mass is that mass which produces at unit distance unit acceleration, its dimensions are in terms of those of distance and acceleration—that is, of length and time only. Pursuing this method a step further, if the properties of the ether are used as a base, only one dimension is needed, since in ether waves there is a fixed natural relation between length and time, and, therefore, the latter unit may be derived from the former. In this system the disparity between the dimensions of the electrostatic and electromagnetic units should disappear. With regard to this it may be remarked that the ether is a more or less hypothetical substance invented to fulfil certain requirements and liable to alteration as these become more defined. Just now, for instance, it is in question whether it should not be given an entirely

Digitized by Google

new property of volume elasticity. When it is added that a particular condition — namely, a wave-length *in vacuo*—must be stipulated for, it does not seem that a system on this basis would be much less arbitrary than one based on the weight of a known substance like water. But, practically, if the system of units is to be changed every few years no one will ever understand it at all. Even such a simple matter as the difference between mass and weight has given difficulty in times past. It would be eminently undesirable to reintroduce that confusion.

Mechanical Traction.—Mr. Angelo Fahie, M.I.E.E., has contributed an article on "Mechanical Traction" to the *Freeman's Journal*. In view of the proposals of the Dublin United and Dublin Southern Tramway Companies, the subject has at present a particular interest for the citizens of Dublin. Starting at once the question of what is the best system of traction, Mr. Fahie says that steam, having had a fair trial and being found unsuitable, may now be considered out of competition, and the problem, therefore, is narrowed down to a contest between the rival claims of electric and cable tractions. The cable system, although somewhat simple, is not by any mean suitable where sharp angles and numerous curves are to be encountered, and amongst formidable objections to it are the enormous cost of construction and the presence of the continuous open slot. As to the efficiency of the system, we have too few cable roads in the United Kingdom to enable us to arrive at any definite conclusion. The best cable roads at present in operation in England are those in Edinburgh, Birmingham, and on the Brixton-road, London. Examples of the system are, however, numerous in the United States, notably the San Francisco, Chicago, and Kansas City lines. In competition with the cable system there are three forms of electric traction to be considered—namely, the overhead, the accumulator, and the underground or conduit system. Of these methods, the first, or overhead trolley wire, appears to be the one which has proved most adequate to the varying conditions of a street tramway service. It must not be assumed, however, that the overhead trolley system is perfect. Its great disadvantage is the unsightliness of the overhead wire, and the necessity of carrying poles, features which would render the introduction of the system to crowded thoroughfares extremely difficult and unsightly. No matter how well planned a tramway line on the trolley system may be, the presence of poles and overhead wires interferes more or less with the æsthetic appearance of city architecture, and, moreover, there is always the danger of a possible impediment to the movement of fire-escapes. On the other hand, an underground or conduit system is not only exceedingly expensive, but it reintroduces the continuous slot, which was one of the objectionable features of cable traction. Lastly, Mr. Fahie refers to the closed-conduit system of the Westinghouse Company, in which there is nothing but a series of contact-pieces projecting slightly above the roadway. "With such an arrangement there is no unsightly overhead trolley wire, and no objectionable open slot in the roadway. The presence of the contact-pieces cannot be regarded in any way objectionable or dangerous, as they project only about half an inch above the surface and present a convex face to the traffic, the edge being flush with the road; the face is also corrugated, so that there is no chance of horses slipping on them." In conclusion, Mr. Fahie strongly urges that this system should be given a trial, at all events in some of the more crowded parts of Dublin, before the city is completely surrendered to the overhead trolley system.

Fuses.—A report submitted to the Philadelphia Board of Fire Underwriters by Mr. W. McDevitt has appeared in full or abstracted in several of the American electrical papers. Mr. McDevitt, apparently, is not one of those persons who are afraid to say plainly what they mean, for he entitles his report, "The Gross Untrustworthiness of Fuse Metals and Appliances as a Means of Protection for Electric Circuits." Mr. McDevitt says that, in spite of the change from wood to porcelain and repeated alterations made from time to time in the terminals, screws, distances between terminals, etc., fuses continue to give trouble. Instances have occurred where the line, although properly fused, has been seen to give off smoke, followed by the virtual roasting and destruction of the insulation. Investigation proved that this was due solely to the sluggish action of the fuse when the circuit was either overloaded or short-circuited. Alloys of different compositions have been used. Some chemical change takes place, either from oxidation or action of the current, resulting in variation in fusing current required. Mr. McDevitt adds: "The gross unreliability of fuse metals, and the lack of dependence to be placed upon the best-designed fuse-blocks used in practice, has forced me to the opinion that in all cases of over 10 amperes capacity, fuses and their appliances, while generally operating as desired, under certain conditions, however, are a serious fire risk, not only in themselves, but in their failure also as a protector." In support of this a large number of tests made in Philadelphia last January are set out, and these are fortified by the opinions of several American electrical engineers on the subject. It is claimed that it is established by these that fuses may carry 50 to 200 per cent. in excess of rated fusing current, or may be so sluggish in action as to be practically useless. Fuse metals made of alloys, so as to have a low temperature melting point, will maintain at a red heat, making a serious fire risk, while metals such as copper, aluminium, iron, etc., are not adapted for fuses, owing to the high temperature required for fusing. In fact, fuse metals are generally unreliable, as their position, length, age, oxidation, shape, composition, temperature, terminals, all affect their fusing point. No standard fuse-block and fuse could be established without some of the above factors causing a variation in the result. The remedy suggested is nothing less than the entire abandonment of the fuse and the substitution of an automatic magnetic circuit breaker, at any rate, in all circuits carrying over 10 amperes. Mr. McDevitt says that during the last few years as a substitute for fuses automatic magnetic circuit breakers have been adopted in power transmission, railway work, isolated lighting plants, and storage battery installations, independently of any requirements of boards of fire underwriters, as engineers have long realised by practical experience the untrustworthy character of fuse metals; and the report concludes by specifying the requirements of an "approved" circuit breaker. Such a circuit breaker would have the features of opening the circuit in less and less time as the conditions of the circuit protected approach a short-circuit—that is, have an inverse time element. The electromagnetic part of the circuit breaker would be designed to develop more energy than is necessary to trip the retaining catch, and the additional energy developed should be applied directly to aid in opening the switch. No springs would be used in adjustment, and all bearing pins and parts liable to be affected by corrosion or rust would be of phosphor bronze, and the moving iron parts copper-plated; while, lastly, the armature or plunger of the magnetic circuit breaker must not act on the retaining catch or switch arm unless a free preliminary movement precedes such action.

ISLINGTON ELECTRIC LIGHT STATION.

The parish of Islington has been the field of much controversy over electric lighting questions. The history of the various attempts of companies to obtain a monopoly in the district is contained in the full report of the Electric Lighting Committee to the Vestry in 1893. Mr. S. Lambert, the chairman of the committee then and now, has been throughout the mainstay of the movement for securing the undertaking to the Vestry. The numerous schemes for lighting the parish previous to 1892 may be briefly summarised as follows:

In 1882 the Metropolitan (Brush) Electric and Power Company applied for and obtained a provisional order from the Board of Trade, but it was subsequently revoked by the Board, as the company did not proceed to work their order. The then Lighting Committee also obtained tenders for lighting parts of Upper-street, but wisely decided to postpone the matter. In 1890 Mr. W. Beale made application to the Vestry for permission to lay electric lines under the footway in the Holloway-road from his premises to the Nag's Head public-house, with a view to supplying the electric light to certain premises abutting on such footway. This application was granted by the Vestry solely as a highway authority. A further application by Mr. Beale for permission to fix 18 arc lamps on the footway on the north-east side of Holloway-road, and to lay the necessary mains for the purpose of supplying electricity to such lamps was granted by the Vestry, and an agreement embodying the conditions imposed by the Vestry in acceding to these applications was entered into. It soon became apparent, however, that the undertaking in the Holloway-road was in reality being carried out by Messrs. Sharpe and Kent, who sought to have the agreement with Mr. Beale assigned to them, a course to which the Vestry did not agree. These gentlemen at the same time applied to the Board of Trade for a provisional order empowering them to light the whole of the parish, but it was not granted, as the consent of the Vestry could not be obtained.

The Camberwell and Islington Company had in the meanwhile obtained an order, but nothing came of it owing to the want of financial support. A committee to consider the advisability of the Vestry undertaking to erect their own electricity supply works was appointed in January, 1892, and obtained advice on the subject from Prof. Henry Robinson. That expert advised the use of the low-tension system, with two generating stations, at a cost of £85,000, to light 24,000 lamps simultaneously. Prof. Robinson also advised that the current could be produced at a cost of 4¾d. per unit, which would permit of it being sold at 5d., but that during the first year's working, at any rate, it would be wise to charge the consumer 6d. per unit; at 5d. he calculated that the cost of the electric light would be about the same as gas charged at Islington. With regard to street-lighting, the professor advised that the cost of lighting a street with arc lamps would be greater than the cost of lighting it by gas, but that if the comparison were made on the basis of light for light the result would come out distinctly in favour of electricity. He strongly advised the Vestry to preserve in its own hands the right to supply electricity in the parish, and so prevent the creation of another monopoly like gas and water. On the advice of the committee, the Vestry obtained a provisional order. The Electric Light Committee then appointed a sub committee to visit various electric light stations and to report as to the best means of supplying the parish. They prepared a most exhaustive report from the information gathered, and showed a thorough appreciation of the advantages of the alternating-current high-tension system for Islington. The final recommendations of the committee were as follow:

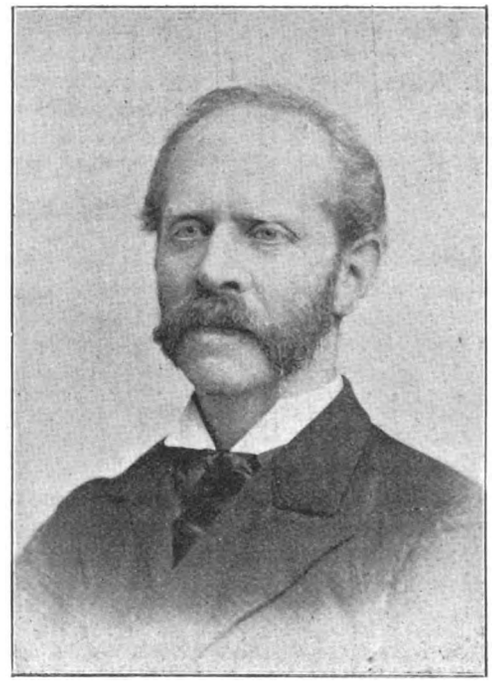
1. That the supply of electric light can no longer be regarded as a speculative business, but, on the contrary, must be admitted to be an undertaking of great benefit to the public and of assured commercial success.

2. That so soon as the Islington Electric Lighting Order, 1893, has been granted by the Board of Trade and confirmed by Parliament it is expedient in the interest of the parishioners that the Vestry should take the necessary steps to carry such order into effect.

3. That it would be both undesirable and expensive to have more than one central station for the supply of electricity in the parish, and that it is desirable to secure a site as central as possible and of sufficient capacity to permit of future extensions.

4. That the high-tension alternating-current transformer system is best adapted for private lighting in a parish of so large an area as Islington, inasmuch as the capital expenditure required for this system would be far less than that of the low-tension or any other recognised system, and on the ground that outlying or scattered parts of the parish could be supplied without much additional outlay (compared with the low-tension system) and without any appreciable delay so soon as the demand for the light in such outlying or scattered districts justifies such extension.

5. That the high-tension continuous current is most suitable for arc lighting in the public streets.



MR. S. LAMBERT, CHAIRMAN OF ELECTRIC LIGHT COMMITTEE.

6. That immediately a site has been obtained, a station be erected suitable for an installation capable of serving 20,000 lights of 8 c.p. burning at one time and about 80 arc lamps for public street-lighting, the Electric Lighting Committee to have discretionary power as to the capacity of the plant to be from time to time laid down until the said total capacity of 20,000 8-c.p. lamps and 80 arc lamps is provided for.

7. That the special committee be authorised to obtain plans, specifications, and tenders for the work and to select an electrical engineer to prepare such plans and specifications on terms to be approved by the Vestry.

8. That a loan of £60,000 be obtained for the purchase of site, erection of building, and the provision of the necessary plant and mains, such loan to be taken up in such sums as may from time to time be required.

9. That it be referred to the Special Electric Lighting Committee to carry the foregoing opinions and recommendations into effect, subject to the consent of the Vestry to the purchase of a site, the designs for works, the appointment and remuneration of an engineer, and to the mode of borrowing being first obtained.

The Vestry adopted the recommendations of the committee, and in July, 1893, appointed Mr. Albert Gay as their engineer to prepare plans and generally to superintend the erection of the works. Mr. Gay advised that the generating station should be erected on some ground

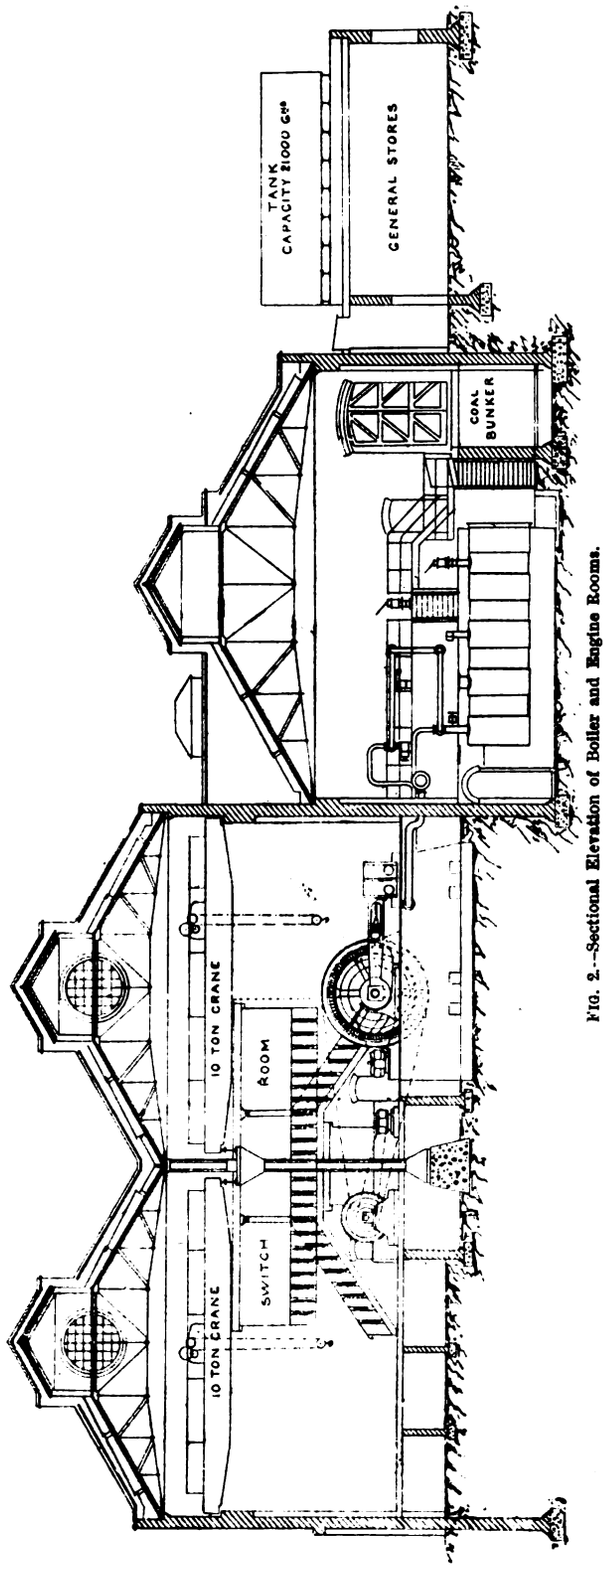

FIG. 2.—Sectional Elevation of Boiler and Engine Rooms.

in Eden-grove adjoining the Great Northern Railway. This position gives great facilities for obtaining coal in quantity, as a siding has been made into the boiler-house. The coal is thus delivered directly into the bunkers. The necessary land, amounting to about three-quarters of an acre, was bought from the Great Northern Railway Company for £9,000, and an additional £257 was paid for the siding. Mr. Gay then prepared specifications for the machinery and mains, while the building specifications were drawn up by Mr. A. H. Tiltman, F.R.I.B.A., for an estimated cost of £17,542. After careful deliberation the following tenders were accepted:

Macfarlane, buildings	£22,785
Morland, structural ironwork	1,944
D. Adamson, Lancashire boilers, engines, travellers, steam-pipes, etc.	8,614
Babcock and Wilcox, water-tube boilers	1,170
J. Fowler and Co., alternators, exciters, and main switchboard	3,925
Elliott Bros., testing apparatus and instruments	830
British Insulated Wire Company, street boxes, pipes, and conduits	£4,333
India Rubber and Gutta Percha Company, cables	7,209
S. Z. de Ferranti and Co., alternator and arc-lighting plant, including rectifiers and switchboard	4,577
S. Z. de Ferranti and Co., transformers	2,128
Chamberlain and Hookham, meters	—

General Arrangement.

The arrangement of the buildings and generating plant can be seen in plan and elevation in Figs. 1 and 2. The general view of the station from the switch gallery is shown in Fig. 3. As will be gathered from these illustrations and the contract price, the buildings are most extensive and substantial. The idea throughout has been to keep extensions in view, although we do not consider it right to penalise a new station with such a heavy building charge. Thus the Islington Vestry have spent nearly £25,000 on buildings only, and yet it is likely that more building will be done directly extensions are started. Commencing with the boiler-house, it will be noticed that the space has been excavated so that the boilers are wholly below the level of the surrounding ground, and also below the engine-room floor. This arrangement has two advantages. The coal can be brought in trucks directly from the colliery on to the rails over the coal-bunkers. There the trucks are up-ended by the apparatus illustrated in Fig. 4, and coal falls through the truck into the bunkers. The floor of the bunkers is on the same level as the stoking floor, and hence very little handling of coal is required. The longitudinal wall between the charging floor and the bunkers is arched, and has a number of openings through which the coal can be taken to the boiler. The engine-room floor is higher than the top of the boilers (as can be seen in Fig. 2), so much so that the steam-pipes rise from the boilers to the engines, all connections being made below the floor line. The engine-room consists of two large bays, each having its own traveller, but the two rope-driven plants come into the space, which otherwise would only be required for extensions. The general design for the extension of the station is as follows: The present shaft, which is 192ft. high, 14ft. 6in. diameter inside at the bottom and 12ft. at the top, is amply large for several more boilers. These will be placed in the present boiler-room, and when that is full a new boiler-room will be erected beyond the chimney, and the engine-room will also be extended. This extension is that likely to be carried out first, and will involve more building changes, as stated above. After this new wing is added and filled, a third boiler-room will be constructed in the space, shown in Fig. 1, between the office entrance and the engine-room. This site, of course, necessitates a second shaft being built. The coal for this boiler-house will be conveyed by the rails showing in the plan. The switch-gallery accommodation will, however, be ample for further use.

The two overhead travelling cranes were made by Messrs. Craven Bros., of Manchester. They are for rope power, and each to lift and travel a safe working load of 10 tons over a span of 41ft. 3in. The cranes were included in Messrs. D. Adamson and Co.'s contract for the steam-engines and boilers. To enable the cranes to be worked before the steam power was available to lift the parts of the steam-engines, provision was made to work them by hand by endless chains working on chain pulleys on the motion shafts of the cranes, the endless chains hanging down within reach of the men on the floor. Now the steam power is available, the driving ropes for both cranes are worked from a small fixed steam-engine in the mechanics' shop, which also drives the machine tools. The long chains for working by hand were taken off, but are available in case they might be required again. The motions are now controlled by eight ropes hanging from the cranes, with handles for putting the motions in and out of gear. Both cranes are driven by their own rope, so that they can be worked independently, and when they are not required the driving rope is stopped by a Snyers friction clutch on the intermediate driving shaft. Messrs. Craven Bros. also made for the same contract a very good device (Fig. 4) for hauling railway coal wagons from the main line on to the line of rails in front of the boilers, and tipping the wagon

Digitized by Google

by the lifting chain. The hauling and tipping frame being hooked on the draw link of the wagon lifts it endways, thus emptying a full wagon of coal without labour. The hauling and tipping motion is driven by an endless rope running along the side of railway rails, and the motions are put in and out of gear by levers on the frame. The driving rope of this is worked by the same engine which drives the endless ropes for working the travelling cranes.

Buildings.

These, as stated above, were designed by Mr. A. H. Tiltman, who does not wish to publish any details of them.

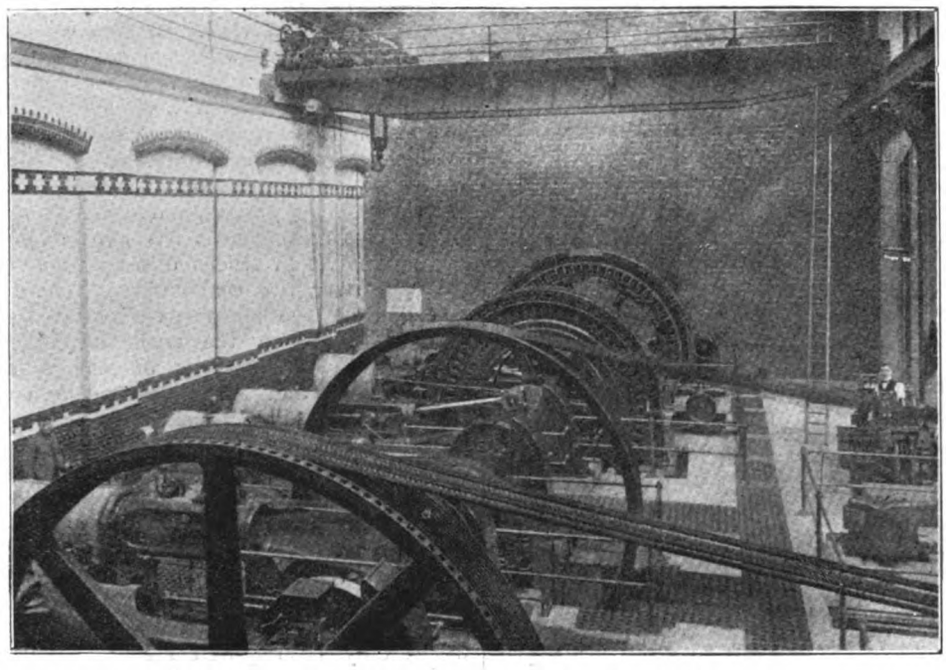

Fig. 3.—View of Engine-Room from the Switch Gallery.

The work throughout is most substantial, and the offices on the first floor are handsomely fitted in mahogany. The interiors of the engine-room and boiler-room are lined with glazed bricks, and this has been carried even to the exterior portions of the stack which are in the boiler-room. The chief objection to this part of the work is the cost; but that is a detail in the hands of the Vestry. One point, however, seems to have been overlooked, and that is, that

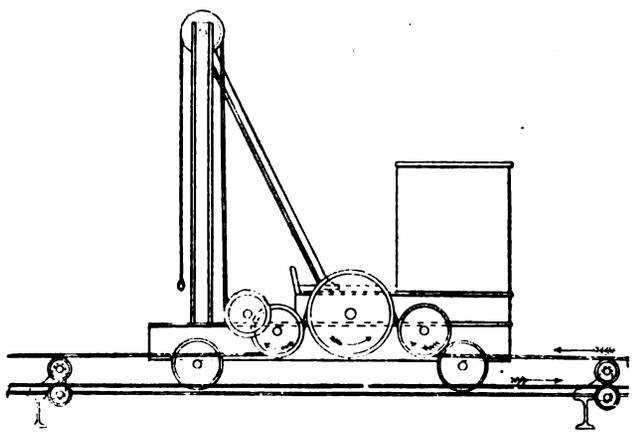

Fig. 4.—Coal Truck Hauling and Tipping Gear.

neither of the travellers can in any way assist in getting the machinery into the building from off either a railway truck or trolley. With the heavy parts required by slow-speed engines and flywheel alternators this is a decided necessity.

Boiler-House Plant.

In this department Mr. Gay is to be congratulated, in that he has combined the advantages of the Lancashire boiler with those of the water-tube type. The present plant consists of four Lancashire boilers and two Babcock-Wilcox boilers. The four Lancashire boilers, of Adamson's latest type, are each 28ft. long by 7ft. 6in. diameter, and suitable for a working pressure of 150lb. per square inch. The boilers throughout are built of the best mild steel. The whole of the rivet holes are drilled and machine riveted with steel rivets. The boilers are fitted with a full complement of mountings and fittings in duplicate. All these boilers and the two Babcock and Wilcox water-tube boilers are fitted with the "Meldrum" patent forced-draught furnaces, which are now being very generally adopted for electric supply stations. In this way the power of the boilers can be largely increased when the full duty is required from the electrical plant. We have before briefly described the action of these furnaces at Stafford and elsewhere, and it is only necessary to add that it is no uncommon thing for these furnaces to give a combus tion of 40lb. of coal per square foot of heating surface This fact alone, when fully recognised, will, we think, tend to the still more extensive adoption of these furnaces by electrical engineers, as it is evident that an electric supply station where the boilers are only fully worked during, say, three or four hours in the 24, any such special means for getting extra duty out of the boilers will materially reduce the steam plant required. What we might term the only objection to this system of forcing the boilers—viz., the noise created by the blowers—has been overcome by the makers, as will be seen by the block (Fig. 5), whereby the air is obtained through conduits leading from beneath the foot-plates, thus effectually deadening the sound, with the further advantage of preventing coal dust, etc., being carried into the blowers when the fireman is cleaning or feeding his furnaces. This refers to the Lancashire boilers, but we find the Babcock and Wilcox boilers are without this improvement. The blowers under these boilers consequently make rather a noise. These furnaces will give the engineer great command over his steam-producing plant when a sudden fog arises, and also will reduce the cost of working, as a lower-class fuel can be burnt at ordinary loads.

Steam-Pipes.

The arrangement of the steam-pipes is, we believe, a novel one, and certainly is to be commended. The view of the top of the boilers (Fig. 6), in conjunction with the general plan of the station (Fig. 1), will enable the system to be understood. In the first place, a pipe is taken from each engine to a boiler. This pipe, which is of ample dimensions to supply the engine, is carried back beyond the boiler connection and then connected past a valve to an equalising pipe. This equalising pipe can then be used to supply any engine if its individual boiler is shut down, or it can and will usually supply the excess of steam

Digitized by Google

required by the engine over its individual boiler production. It will be seen that at present there are six boilers and only four engines, so that one boiler feeds into this equalising pipe only. The dimensions of the largest steam-pipe is thus kept down to a smaller limit than with the ring-main system. An equal degree of safety is also secured with a fewer number of valves.

All the steam, feed, blow-off, and other pipes were supplied and erected by Messrs. D. Adamson and Co., and are arranged in duplicate. The pipes are of forged mild steel fitted with strong cast-iron flanges, and all joints are simply made with ordinary cement. The exhaust steam from all the engines is delivered into the main chimney stack by a forged mild-steel riveted-up exhaust-main, and provision is provided so that the exhaust may be taken either direct into the stack or through feed-water heaters. A complete set of by-pass arrangements, both for feed and exhaust, with the necessary valves, has been provided for this purpose. The feeding of the boilers is also provided for, either by duplex pumps or injectors, in duplicate feeding direct. Every means has been provided throughout so that in the event of any portion of the system being required to be shut off, it is possible to keep running with the remainder of the plant.

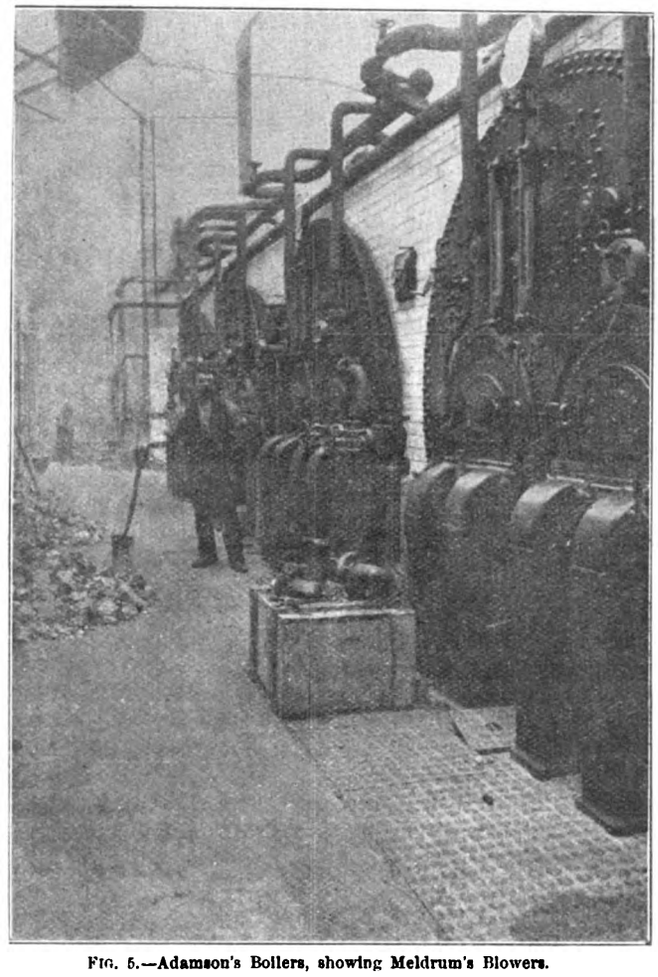

FIG. 5.—Adamson's Boilers, showing Meldrum's Blowers.

STEAM-ENGINES.

The four engines supplied by D. Adamson and Co. (Fig. 7) are of the horizontal, high-pressure, compound, non-condensing type, with cylinders arranged side by side. The high-pressure steam-cylinders are 15in. diameter, and the low-pressure cylinders are 24in. diameter, each having a 3ft. stroke. They run at 95 revolutions per minute, giving a piston speed of 570ft. per minute. Both the cylinders are steam-jacketed, with high-pressure steam direct from the boilers, the jackets being coupled with suitable valves and connections to an automatic steam-trap. The engines are intended to develop from 200 i.h.p. to 225 i.h.p., with a steam pressure ranging from 125lb. to 150lb. at the cylinder. The cylinder bodies and covers are lagged all over with non-conducting composition, and neatly finished with planished sheet steel and brass hoops; they are also fitted with a full complement of spring relief valves, drain and indicator cocks. The valve gear fitted to both cylinders is of the latest improved Wheelock type. The system is that of having the valve seats independent of the cylinder castings themselves. The valve seats are made in the form of a plug, which contains both the steam and exhaust valves. The valves are of the flat grid type, with multiplicity of opening and short travels. The high-pressure valves are directly and automatically controlled by a high-speed governor, driven by ropes from the main shaft of the engine, whilst the low-pressure valves are fitted with an expansion gear arranged to be regulated by hand whilst the engine is in motion. The crankshafts are of forged mild steel, and are 8in. diameter in the journals, and the journals are 18in. long; they are fitted into brass steps lined with magnolia metal. The engine cross-heads are of mild cast steel, fitted with loose cast-iron slippers running in bored guides in the engine frame. The cranks are of the disc type, polished all over, and of mild cast steel, and fitted with mild-steel crank-pins 6in. diameter by 6in. long. The connecting-rods are also of forged mild steel, and are fitted at each end with adjustable steps, the brass shell steps being lined with magnolia metal. The piston rods are also of mild forged steel, and are 3¼in. diameter. From two of these engines the alternators are driven by means of ropes from the engine flywheel. The flywheels are 14ft. diameter, and are turned on the rim for 10 ropes 1¼in. diameter. The other two engines are fitted respectively with a flywheel alternator—one by the Leeds and London Electric Company, and the other by Messrs. S. Z. de Ferranti, Limited. The engines generally are complete with automatic lubricators for every part, so as to ensure continuous running. Oil splash guards and oil-collectors are fitted round wherever possible, all the waste oil being led by an arrangement of pipes to the oil-tank in a convenient place in the engine-room, where it is refiltered for further use. The whole of the bearings in the engines, alternators, etc., are also fitted with a cold-water service,

Digitized by Google

coupled direct to the City mains. All the alternators and dangerous parts round about the engines are also fenced with polished rails and cast-iron standards.

ALTERNATORS.

There are at present four 100-kilowatt alternators in the station. The first two (Fig. 8) are rope-driven, at a speed of 375 revolutions per minute. They all are wound to give a pressure of 2,050 volts. The two rope-driven plants and the first flywheel alternator were supplied by J. Fowler and Co., of Leeds. The first named are of the usual type, having revolving field magnets of laminated iron. The armature core is constructed so that any section with its coil can be removed in case of failure and quickly replaced by a fresh interchangeable section. The machines have three bearings. The frequency of these alternators is 50 complete periods per second.

The remaining flywheel alternator was supplied by Messrs. S. Z. de Ferranti and Co. It is of the same type as the large alternator supplied by that firm to Portsmouth, but several modifications and improvements in detail have been made in it. As a consequence, the alternators are practically silent when running. The alternator has been designed with a stiff field and small armature reaction, so that the machines may work well with the rectifiers and their motors. The alternator has a large air-gap to get these results, which, of course, necessitates a slight increase in the excitation. The field-magnet system is built up on the flywheel of the engine, radial poles being inlet into the rim. These poles are wound with bare copper strip on edge, with insulation between the adjacent turns. The armature consists of a series of wedge-shaped segments built up of laminated iron. The plates have holes punched in them, through which the conductors are wound. The complete segments are then bolted individually in place on the cast-iron frame. As in all the other alternators, the exciter for this set is driven by ropes from a pulley on the alternator shaft.

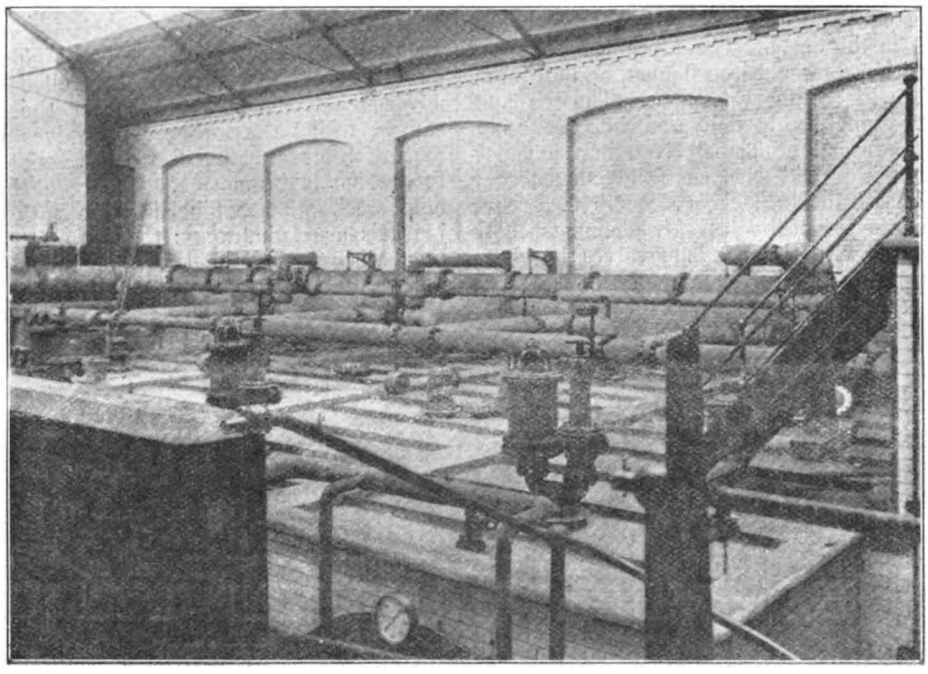

FIG. 6.—View of Steam and Exhaust Pipes.

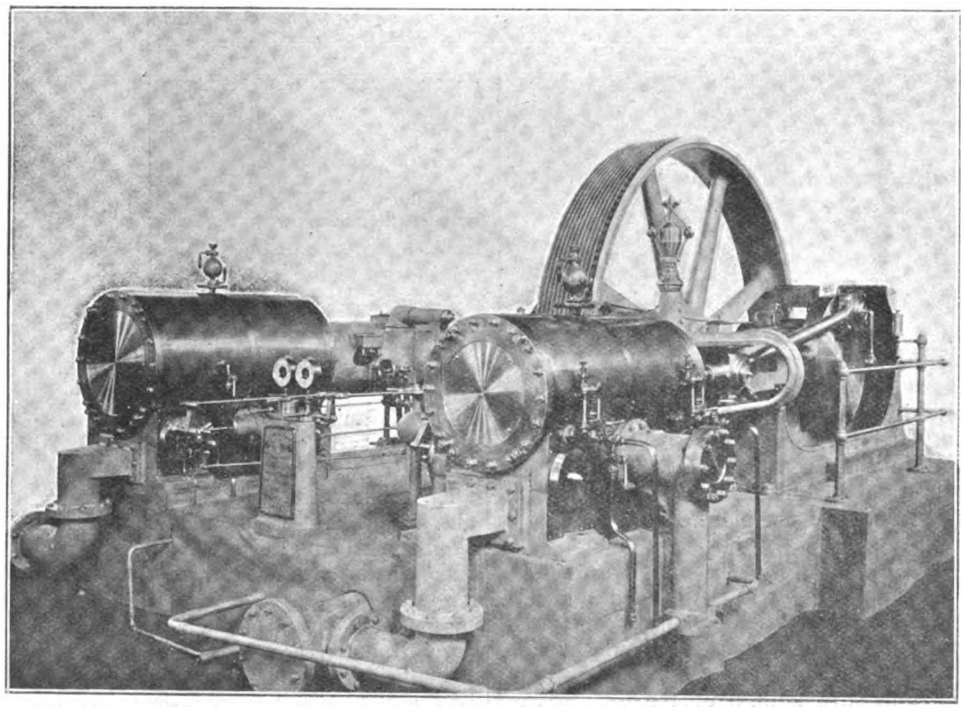

FIG. 7.—Adamson's Horizontal Engine, supplied to Islington.

Digitized by Google

Switchboards.

These, with the exception of the arc lighting boards, were supplied by Messrs. Fowler and Co., and the instruments for them by Elliott Bros. The general position of the switch, etc., can be seen in Fig. 9. Beginning at the bottom of the board, the lower fuses are the alternator fuses, above which come the ammeters in the alternator circuit. In the next case are the alternator switches, which are of the well-known plug type. Above these are the electrostatic voltmeters, of which only four are fixed at present, one for each alternator. Above these come the circuit switches, ammeter, and fuses respectively. The pillars in front of the board carry the rheostat regulators for the exciting circuits, with ammeters and voltmeters. Each exciter is strictly kept to its own alternator, and no means of inter-connection are provided. Thus, a breakdown in an exciter will render the alternator *hors-de-combat* as effectually as if it was burnt out. The alternators are arranged for working in parallel, but the synchronising panel cannot be seen in the illustration.

Messrs. Elliott Bros. also supplied a complete test table equipped with all the instruments for testing cable, conductor, and insulation resistance, and capacity, etc. All the instruments, except the galvanometer, are mounted on a strong teak table. The galvanometer is fitted in a swinging frame, so arranged as to be unaffected by vibrations. The other apparatus consisted of a photometer, speed and pressure indicators and recorders, steam-engine indicators of the Wayne high-speed type, recording voltmeters, and a non-inductive resistance for use as an artificial load.

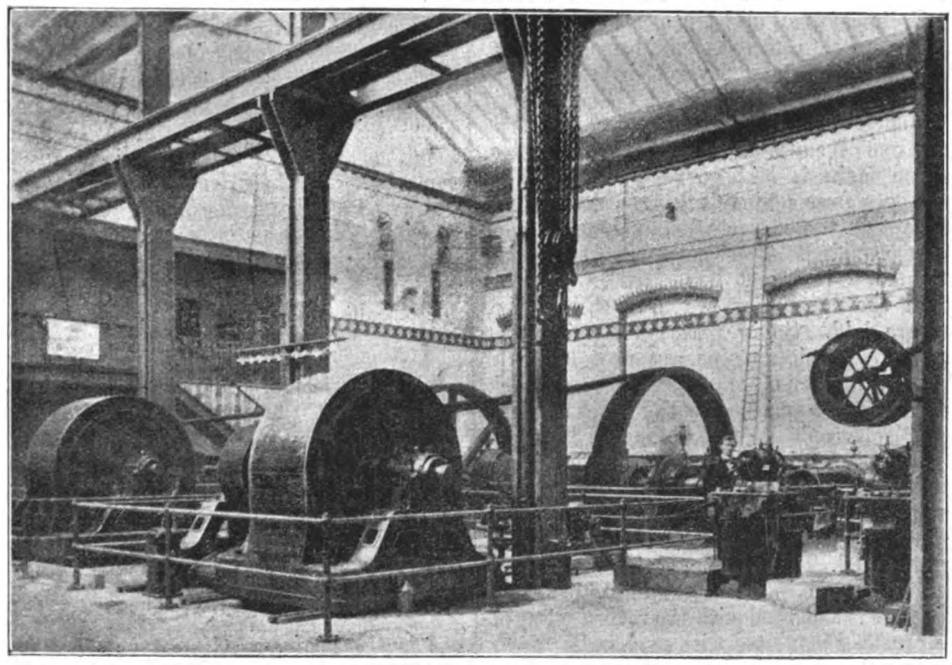

Fig. 8.—View of the Rope-Driven Fowler Alternators and Ferranti Rectifiers.

Arc Lighting Gear.

This has all been provided by Messrs. Ferranti and Co. There are at present five rectifiers, each capable of supplying 30 arc lamps; four of these are for use and one is spare. The switchboards are so arranged that any rectifier can supply one arc circuit. The construction of the rectifier and the constant-current transformers was fully described in our Tunbridge Wells issue of October 4, 1895. The arc lamps used are of the Crompton-Pochin type, and 96 are

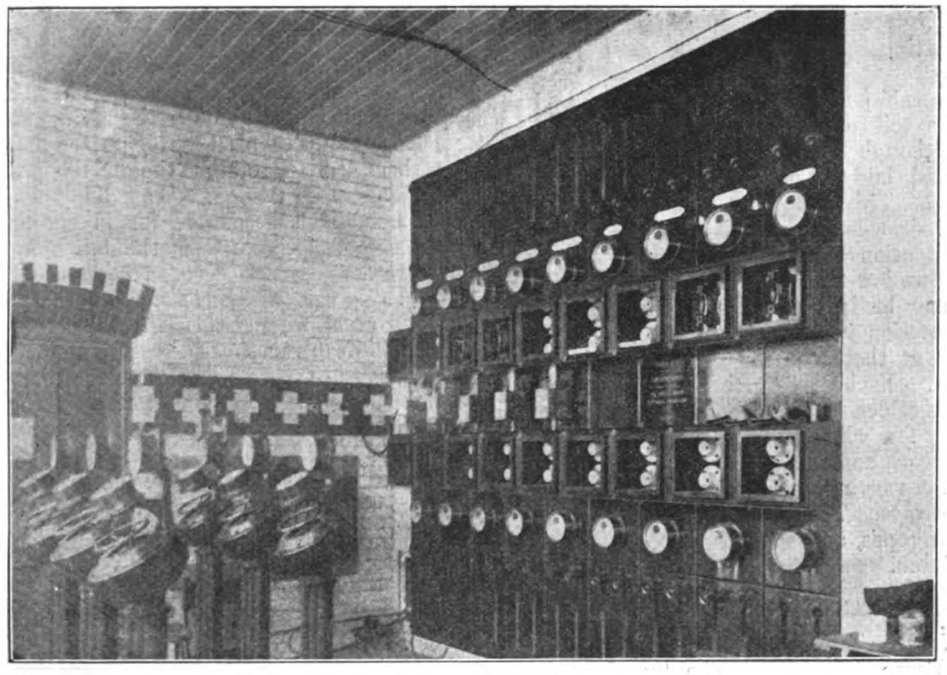

Fig. 9.—Islington Switchboards.

Digitized by Google

now fixed and ready for running. The circuits are arranged one for each side of the streets lighted, so that half the lamps can be switched off at midnight and yet a uniform distribution of light be obtained. The lamp columns were manufactured and supplied by Messrs. W. Macfarlane and Co.

Distributing System.

The cables at present laid in Islington extend about 1½ miles each way from the station. They reach from Eden-grove along Holloway-road and Upper-street, past the end of Essex-road, nearly to the Angel in one direction, and along Holloway-road and Seven Sisters-road to Finsbury Park Station in the other direction. There are at present no branch mains or feeders, and the system is the old and elementary one of supplying long mains from one end. A high-tension main is laid on each side of these roads, and each of these four mains is kept quite distinct from the other except at the extreme distant point, where connectings links are provided. The consumers are supplied from transformers placed in street boxes under the footpaths. Then, when the consumers are near each other, low-tension mains are laid. So in parts of Upper-street some 1,000 yards of low-tension mains are now laid and supplied at points by a number of transformers in parallel. The whole of the cables were supplied by the India Rubber, Gutta Percha, and Telegraph Works Company, Limited. The high-tension cables vary in size from $^{19}/_{18}$ to $^{7}/_{16}$, and are of the concentric type.

The conductors are of strand composed of copper wires of 100 per cent. conductivity by Matthiessen's standard, each wire being carefully tinned. The whole are laid up together, and then insulated with pure indiarubber and vulcanising indiarubber. This part is sheathed with the return wires of tinned copper, then further insulated with pure indiarubber and vulcanising indiarubber and taped over all. The whole cable is afterwards vulcanised together, then braided with hemp and sheathed with two steel tapes, and again hemp braided over all. A final coat of preservative compound is is served on. The cables specified had a total length of over 30 miles, all the joints being vulcanised. The insulation resistance per mile at 60deg. F., tested in water after 24 hours' immersion, and one minute's electrification, is not less than 5,000 megohms between conductors for the high-tension cable, and 2,500 megohms over all. The low-tension cable had an insulation resistance of not less than 600 megohms between conductors, and 300 megohms over all. The high-tension cables, after being tested with 5,000 volts alternating, showed no falling off in insulation resistance.

The low-tension cables are of $^{19}/_{14}$, and are armoured and laid direct in the soil under the footpaths. The high-tension cables, although armoured, are drawn into iron pipes supplied and laid by the British Insulated Wire Company, Limited. This company supplied to the Vestry all the pipes and draw-boxes, as well as the house-service boxes for the low-tension cables. These house-service boxes each provide for two low-tension mains in parallel, so that the second one may be laid and coupled up subsequently to the first. Provision is made in each box for disconnecting the mains at that spot, for testing or jointing on further customers. Each box further provides for four concentric service cables, each with separate clamps and double-pole fuse. The whole service box is provided with a telescopic framework and surface cover, so that allowance can be made for the varying depths of the cables below the surface of the footways. The arc lighting mains are drawn into 4in. cast-iron pipes, and inspection boxes are placed at every lamp column.

Transformers.

The contract for the supply of these was obtained by Messrs. S. Z. de Ferranti and Co. The transformers, for the most part, are of the Ferranti automatic type, with two windings for both the primary and secondary circuits. Automatic gear is then provided, so that at light loads the two windings in each circuit are put in series. This, by doubling the number of active turns, halves the maximum induction, and reduces the iron losses to about one-third of the original value. At heavy load the circuits are put in parallel, and then the copper circuits act most efficiently. Some 20 of these automatic gears and transformers have been supplied, and about five others of the ordinary type. The output of these transformers varies from one kilowatt up to 20 kilowatts. We should unhesitatingly recommend these arrangements if the transformers were of the type manufactured, say, in 1888, but with the present high standard of efficiency in transformers we rather question if the small saving is really worth the risk incurred should the automatic gear fail.

In conjunction with each transformer is a high-tension ring-main junction-box of very excellent design. This box allows of disconnecting the main or the transformer, or of leaving the transformer on either branch of the main when disconnected. The main is bridged by heavily-insulated plugs, which, however, can, when desired, be replaced by oil break-fuses, either in case that section is suspected or for testing purposes. The connections to the transformers are made by an oil break-fuse on the high, and a plug on the earth, main. Arrangements are made in this box so that it is impossible to get into connection with the circuits, or to cause a short by dropping anything in.

Scale of Charges.

The provisional order granted by the Board of Trade provides that the maximum charge to be made by the Vestry for the actual amount of energy supplied to a consumer shall be for any amount up to 20 units 11s. 8d., and for each unit over 20 units 7d. The committee have resolved to adopt the following sliding scale of charges for the first 12 months with a view to enabling all consumers to have equal opportunities for obtaining discounts:

For the consumption of two hours per day of the maximum demand, 7d. per unit.
For the consumption of three hours per day of the maximum demand, first two hours 7d., the second hour 6d.
For the consumption of four hours per day of the maximum demand, first two hours 7d., the second two hours 5d.
For the consumption of five hours per day of the maximum demand first two hours 7d., the second three hours 4d.
For public lighting, 5d. per unit.

The average price which it is estimated will be obtained from consumers with this sliding scale is 6d. per unit.

The meters used have been supplied by Messrs. Chamberlain and Hookham, and Wright's excess demand indicators will permit of the graduation of charges being effected.

Conclusion.

Although the committee took expert advice at the very beginning, they throughout discarded the consulting engineer, by which they claim to have saved £4,000. From the figures before us, we doubt the saving, and also the statement in a non-technical contemporary that "the installation has been carried out at the lowest possible cost to the parishioners." Some £85,000 has been spent, of which only £65,000 is accounted for in the contracts. For this large sum 400 kilowatts is the maximum output, without any reserve, which gives a cost of £212 per kilowatt. Comparing this with Leicester, where flywheel alternators are also used, we find there 675 kilowatts installed at a cost of £38,700. This gives a cost of under £58 per kilowatt. We may add that the Leicester buildings are most handsomely appointed, and the details of the machinery there well carried out. Of course, much allowance must be made for the cost of the site at Islington, but a matter of £10,000 will not bring the two sets of figures within reasonable bounds. Another point worthy of notice is that the expenditure exactly equals that recommended by Prof. Robinson, and for which he could maintain 24,000 lamps alight on the low-tension system. The present machinery will only supply some 12,000 lamps simultaneously.

ELECTRICITY IN CONNECTION WITH BUILDING.

LECTURE BY MR. W. H. PREECE, C.B.

A large audience assembled at the Carpenters' Hall, Throgmorton-avenue, on Wednesday to hear a lecture by Mr. W. H. Preece, C.B., on "Electricity in Connection

Digitized by Google

with Building." The chair was taken by Sir Arthur Arnold (chairman of the London County Council).

Sir ARTHUR ARNOLD, in introducing Mr. Preece to the meeting, said, as chairman of the London County Council, it was to him a very great satisfaction to preside in one of the halls of one of the most distinguished of the City companies and to see that hall devoted to so noble and to so useful an object. Mr. Preece was a very distinguished electrician, and a man who had been, perhaps, beyond and above all other men in the City of London, a man of light and leading among them for the last 40 years. No man certainly had rendered so great service to popular electricity in its most useful forms as Mr. Preece.

Mr. PREECE said: Sir Arthur Arnold, ladies, and gentlemen—With such a eulogistic introduction I feel that I fear that I shall not quite come up to your expectations, for it is indeed an extremely difficult task to address you on such a difficult subject as the application of electricity in connection with building. I do not know quite what you expect me to say. I do not know whether you think that electricity, which is going to do everything in this world, is going to replace bricks and mortar, or whether it is to be utilised as an economiser of labour in lifting materials and in breaking down trades' unions by disestablishing carpenters; but I am going to take this line—that inasmuch as the secrets of good health, apart from personal habits and the correct maintenance and up-keep of the human machine, are pure water to drink, pure food to eat, pure air to breathe, cleanliness in dwellings, in furniture, and in clothing, warmth and light, so I propose to point out to you how electricity in nearly all these points can aid those who desire to support and lengthen life by supplying all the particulars that I have named. Now, legislation enforces sanitation, Government inspects food products, it facilitates the supply of water, it controls the manufacture and consumption of gas, and in the same way it controls the supply of electrical energy, and this electrical energy, as well as gas, is utilised not only for the production of light, but for the generation of heat and for the supply of power. In this great city of ours we have two great powers—first, as we are here, I think I will say the Corporation of the City of London; secondly, as we have such a distinguished chairman to-night, I will say, the London County Council; and in these two bodies we have the representatives of all those local authorities who are to be found throughout the whole country; and in their hands Government has placed the control of the different powers for good as I have enumerated. Well, now, have those bodies, as a rule, carried out the functions that the Government have handed over to them? To a great extent they have. But there are instances throughout this country of great backsliding and retardation. In the City, in London, in Greater London, electricity is applied to a certain extent, but nothing compared to what it ought to be, and to what it will be. We are restricted in small communities by various causes, first of which is ignorance, and this, often wilful, is frequently due to indifference, and generally due to blindness. I know nothing in my experience more difficult than to try to convince a vestry, or a county council, or a town council with the doctrines of the benefits of electric lighting. I am met on all sides with objections, some due to conservatism—the true Conservative is the most difficult gentleman to move; the next most difficult gentleman to move is the Radical, because he thinks that we are introducing class legislation—he fancies he is asked to do something that is going to benefit the wealthy and aristocratic classes; and the next is the interested individual—the gas shareholder. Now, I find, I am bound to confess, that there is more trouble with that gentleman than any other, and as I am a pretty considerable gas shareholder myself, I have found that my friends the gas companies are terrible people to convince against their will. However, in spite of all this, in spite of the worst of all, and that is party spirit—in every community you have it; you have it in the London County Council, and our own Parliament is divided into two parties—and if one party proposes the introduction of electric light the other party is sure to oppose it, not because there is anything in it, but because the other fellow cannot do that which is right. However, in spite of all this we are going along, and we are going along splendidly. The advance of electrical industries in this country is quite equal to our most sanguine expectations. It is a common thing to find in the Press complaints that we in England are far behind anybody else, especially America. That is not my experience. I have visited America many times, and while there is no doubt that in some respects the Americans are very go-ahead, in other respects we in this country are quiet, and we are certain and we are sure; and in electric lighting in England, as applied where we want it—that is, for private purposes—we are certainly in advance of our cousins on the other side of the Atlantic. Now, the supply of electrical energy in this country rests entirely on two sources—one controlled by private enterprise, and the other in the hands of local authorities. It is a very moot question indeed as to which is the best source or the best means of forcing on this industry. In a pioneer business, such pioneer businesses as I have been associated with—and it is a remarkable fact that in my career I have been associated with the introduction of every single application of electrical energy; I was connected with the early introduction of telegraphy and of telephony, with the electric lighting, with electrical tramways, and with everything else connected with electricity—I find this, that owing to the fact, I am sorry to say, of public companies and private companies having no conscience, pioneer works are best originated and supported and started by private enterprise. When they are well fixed and well established, that is, I think, the time first for the Government to step in, in some industries, and for local authorities to take up the same position. Now, I am sure that the telegraphs would never have acquired their present position if the Government had started the industry. Competition, money-grubbing, and all sorts of causes led to the great development of this industry, and when it became a public necessity, when it became everybody's business, then properly the Government stepped in, absorbed the telegraphs, and took me into their service, and the result of the absorption has been that the telegraphic system of this country is the finest and best in this world. Now that local authorities, too, take over industries for the benefit of the whole community—water supplies, sanitary arrangements, etc.—the supply of light is, I think, the proper function of a local authority. A local authority is bound to look after the health of the community, and anything that adds to the health of the community must necessarily come within their sphere; and so it is that throughout the whole of this country we find our corporations taking up this subject of electric lighting. And what is the result? The result is that the cost of production, which regulates the cost to the consumer, is coming down, and the rate at which the cost of production is being lowered is quite astonishing to those who are watching carefully the progress of events. Of course, the cost of production regulates the price that the user has to pay. We find in this London of ours that there is great variation in the cost of the supply of electrical energy to the community. Take the City of London. In the City of London—which, unfortunately, from some points of view, is in the hands of a private company—the users have to pay at the rate of 8d. per unit; when you go to one of our outskirts (say, the parish of St. Pancras or the parish of Hampstead), there electrical energy is supplied at the cost of 6d. per unit, so that those who are obtaining their energy under the auspices of local authorities are benefited in the ratio of 8 to 6.

(To be continued.)

Holophane, Limited.—The prospectus of this Company has been issued. The Company will acquire and work the patent rights of Messrs. Blondel and Psaroudaki, the inventors of the holophane globe. The capital is £100,000 in £1 shares, of which the vendor takes 25,000 in part payment; 65,000 are now issued, and 10,000 left over for issue as further working capital. The list opens on Monday next, and will close on March 12. It will be remembered that the holophane globe is grooved inside and out in different directions, the object being to diffuse the light. A full description of the globe was recently given in our columns.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

FOR MEMBERS OF LOCAL AUTHORITIES.

The members of local authorities, unless personally interested in other directions, never have any objection to push forward objects that are looked upon with some favour by their constituents. Throughout the length and breadth of the land authorities are more and more considering the directions in which the authorities themselves should move, and not allow the work to fall into the hands of a company. One of the questions under consideration is that of the electric light, and those who are advocating its introduction are frequently seeking "tips" to assist the good work. Of course, the very best statement to make is that the experience gathered in every direction proves the work to be paying. It is not always that a new manufacturing industry pays its way during the first year, but in almost every instance the authorities have cleared during the first year all expenses, and in some cases have earned a small amount towards interest and repayment of capital. After a comparatively short period, not only do the works clear expenses, but easily return the amount required to repay capital, the success ending in reducing price or relieving rates. This phase of the question, however, is best ascertained from the many reports and balance-sheets we are continually giving. However, the success might be far greater and the benefits received all round considerably extended if this system of artificial lighting was generously and generally adopted, instead of percolating slowly downwards through large users to the smaller users of light. One great difficulty to be encountered is the feeling of a constituency that no doubt the work will pay, while individually the members of the constituency leave it to their fellows to patronise the new scheme. Mr. Jones will wait a little to see how Mr. Brown gets on, and Mr. Brown waits for Mr. Smith, so that the first patrons are difficult to get, and this makes the initial work harder, though all the time the householders are intending to patronise the light—some day. Thus advocates not only have to show that generally the work is likely to pay, but they must canvass the individual and reason him into taking current. How can he be induced to move? What arguments will prevail? It seems to us that, after cost has been discussed, sanitation is the best lever to work. No one can ignore this part of the subject. If light is essential to health, still more essential is it that the light be pure. Statistics are given stating that for the same illuminating power the comparative heat of various lights is—for electric light 14, common gas 279, sperm oil 234, paraffin candles 362, tallow candles 505; but this is not the worst—heating property may be good, but when accompanied by a vitiation of the atmosphere may be bad. A man requires for breathing purposes some 3,000 cubic feet of air per hour, a sperm candle 1,500 cubic feet, an oil lamp 3,000 cubic feet, a gas-burner (5ft. per hour) 20,000 cubic feet, so that a lamp consumes air equal to a man, as do two candles, while a gas-burner is almost equivalent to seven men. Local authorities often have to consider the lighting of large buildings, and one of the

Digitized by Google

questions asked is how many lamps will be required. A rough-and-ready rule is to take the floor-space area in feet, and divide this number by 40, the result being the number of 5ft. gas-burners required; and, again, broadly speaking, you may assume that such a gas-burner is about equivalent to a 16-c.p. incandescent electric lamp. Many engineers would probably use a divisor of 60 rather than 40, but we prefer the divisor that gives "more light." Just one more point where differences of opinion arise, and, as we think, uselessly. In many, far too many, places ample light is obtained, then some decorative or artistic mind is brought to show how to get rid of a large part of the light. There is no material known which can be used as a shade to light or be interposed between the light and any given point without causing a loss of light. Ordinary glass intercepts 10 per cent., ground glass 30 to 50 per cent., opal globes 50 to 60 per cent., and porcelain as much as 98 per cent. of the light; hence it seems at times a pity that light is only generated to be intercepted. A good system of diffusion, with less light in the first instance, would ofttimes be better than the interception by means of various shades.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LAMP BREAKAGES.

SIR,—Our attention has just been called to a note which appeared in your issue of the 28th ult. under the heading of Worcester, wherein it is stated that the breakage of lamps at the Victoria Institute was due to their cheap quality. Will you allow us space to correct that statement, as it is likely to do us harm, as we were the contractors who supplied them.

The true facts are these. We were informed that the E.M.F. was 100 volts, and we supplied lamps (not of German manufacture) of that pressure, and guaranteed them to run for 1,000 hours. At the end of a fortnight about 28 had broken out of 480. We therefore tested the pressure, and found that, instead of 100 volts, it was 106 to 107. It is, of course, hardly to be expected that lamps would stand such overrunning. The committee have now decided to instal German lamps of the proper voltage, and in the meantime we have to suffer for other people's mistakes.

We are, however, so confident of the quality of the lamp that we have written the committee asking them, in common fairness, to allow us to fix up, say, 12 of our lamps at 106 volts in competition with the lamp selected, so as to prove to them that the breakage was through excess of pressure.—Yours, etc., GRAHAM AND BIDDLE.

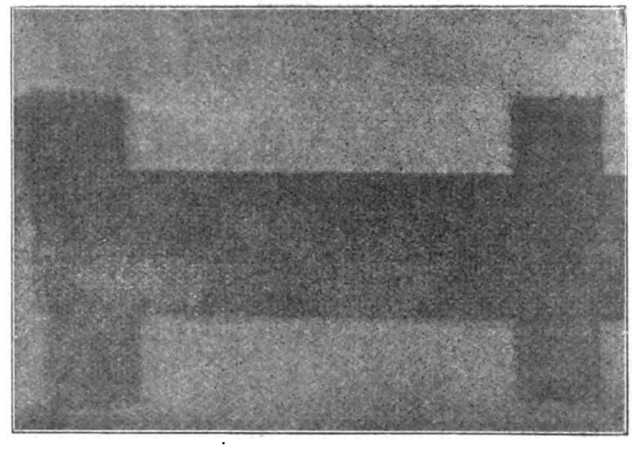
461 and 463, Oxford-street, W., March 3, 1896.

THE NEW RAYS.

SIR,—The following experiment, which was made on February 11 (a brief account of which appeared in the *Daily Telegraph* on February 20), appears to determine that the cause of the phenomena which Prof. Röntgen was the first to discover is the direct result of electric stress, and not, as was supposed, of invisible light.

A No. 14 B.W.G. cotton-covered copper wire was bent five times upon itself in parallel lines. It was then fastened to a piece of cardboard by stitching it at each bend and midway between the bends. A very thin magnetic strip was then placed across the back of a photographic plate, its position being maintained by small pieces of postage-stamp paper. The photographic plate, with the magnet at its back, and the cardboard with the wire attached as described, were next very carefully wrapped up in ruby paper, which was again covered with black paper, the wire on the surface of the cardboard resting on the sensitive surface of the photographic paper—*i.e.*, nothing intervened but the cotton with which the wire was covered. It should also be stated that previous to enfolding the apparatus in the paper, the terminals of the wires were bent back upon the outer surface of the cardboard, and that the whole process was conducted by a photographer in his dark-room. The terminals of the wires were then connected with the wires of a Fowler's alternator dynamo giving 40 periodicities per second, and a current of about eight amperes was sent through the wire for about 47 minutes.

After the development of the results by the photographer on the following day examination showed not only the complete image of the magnetic strip, but of the stamp paper also by which it was affixed to the glass, together with a representation of the red line which exists near one edge of the paper and the segments of the perforations where the stamps had been torn away. It is particularly worthy of notice that these effects were the product of stress in the wire exercised through the glass plate upon the magnet and the paper. It is perhaps well to add that I have obtained similar results upon two other occasions, when the method of conducting the experiments under electromagnetic stress and with the total exclusion of light was upon somewhat different lines. I am sending a photographic copy of the first stress image which I obtained by the process described above. The magnetic strip is seen in the centre, and the two pieces of stamp paper crossing the ends of the magnetic strip.



I may, perhaps, be permitted to explain the very simple process by which, as it appears to me, all photographs are taken, and also the intimate connection which exists between photography and those stress images, or pictures, which are capable of being obtained by the Röntgen rays, or by the stress of magnetism, electromagnetism, or any stress-propagating body. It is well known that all forms of matter are polar—*i.e.*, they assume a definite direction when they are free to move in a magnetic field. As a matter of fact, owing to terrestrial magnetism, all matter exists in a magnetic atmosphere—*i.e.*, every molecule of matter is a stress-creating body—and from such cause takes a special direction when free to move and it is acted upon by other matter. Light is one of the disturbing elements, and therefore when it falls upon the sensitive surface of a photographic plate, the molecules are thrown into motion. Now, as the matter in question may be said to have one general uniform material condition, it is obvious that the general effects upon the surface would be the same, provided the light impinged equally upon all portions of it, but that when it is *reflected* from any image, the counterpart of that image would be produced upon the plate, because the impressions and the molecular motion would vary with the character of the image.

Passing now to the images or pictures, etc., which are obtained by the stress of magnetism, electromagnetism, or

Digitized by Google

possibly of almost any other mode in which stress is capable of being propagated, the same principle holds good, for the sensitive matter upon the surface of a photographic plate registers the various directions in which impressions have been conveyed directly or indirectly to it and through *intermedial* bodies. Thus if the stress be the effect of a Röntgen tube, or of any other similar medium, any object which intercepts or otherwise deals with the lines of stress modifies proportionately the effects made upon the plate, and therefore it is that the images laid down upon the plate are correct representations of the bodies which in proportion to their density have interfered with the lines of stress. A cause is thus found for the disappearance of the flesh of the fingers, etc., as is known to occur when the stress has been so increased as to render these tissues quite transparent, whilst those of greater density remain. Upon this principle, also, we recognise the cause of aluminium, one of the lightest of metals, transmitting the rays (stress), whilst iron, lead, and other bodies of considerable density are rendered very apparent.

I may further add that I take a special interest in this subject owing to the intimate connection which exists between it and a theory which I published in the *Electrical Engineer* in 1894 as to the nature and cause of gravity, together with the theory which I have long advocated as to the nature of the process by which animal life is carried on.—Yours, etc.,

RICHD. C. SHETTLE.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

March 6, 2.30 p.m.—Students' visit to inspect the St. Pancras refuse-destructor works. (Assemble at the Works, Georgiana-street, Great College-street, within two minutes' walk of the Camden Town Station, North London Railway.)

March 10, 8 p.m.—At Great George-street, Westminster. Ordinary meeting. Discussion of paper "On Littoral Drift in Relation to River Outfalls and to Harbour Entrances," by William Henry Wheeler (member). And, time permitting, papers to be read: "The Lixiviation of Silver Ores," by J. H. Clemes (associate); "Mining and Treatment of Copper Ore at Tharsis, Spain," by C. F. Courtenay (member); "Tin Smelting at Pulo Brani, Singapore," by John McKillop and T. Flower-Ellis.

March 13, 8 p.m.—Great George-street. Students' meeting. "Tests of Centrifugal Pumps," by J. C. Cornock (student).

Institution of Electrical Engineers.

March 6, 8 p.m.—At the Library of the Institution, 28, Victoria-street. Paper on "A Simple Method of Analysing Harmonic Curves," by E. Basil Wedmore (student).

March 12, 8 p.m.—At the Institution of Civil Engineers, 25, Great George-street, Westminster. Discussion on Mr. G. L. Addenbrooke's paper on "High-Voltage Lamps and their Influence on Central-Station Practice."

March 13, 8 p.m.—At the Library, 28, Victoria-street. Students' meeting (extra) Discussion on Mr. Fennell's paper on "Central-Station Experiences."

March 14.—Visit of Students to Messrs Siemens's Works at Charlton. Train leave Charing Cross at 10.20.

Northern Society of Electrical Engineers.

March 9, 8 p.m.—At the Palatine Hotel, Hunt's Bank, Manchester. Discussion on the paper on "The Parallelling of Alternators," by Robert Hammond.

Society of Arts.

March 10, 8 p.m.—At John-street, Adelphi. "English Book Illustration, 1860-70," by Joseph Pennell.

March 11, 8 p.m.—"Peasant Life and Industries in Ireland," by Prof. A. C. Haddon.

Physical Society.

March 13.—At Burlington House. Papers: (1) "An Addition to the Wheatstone Bridge for the Determination of Low Resistances," by Mr. J. H. Reeves; (2) "On Kathode Rays," by Herr Puluj.

Institution of Junior Engineers.

March 6, 8 p.m.—At Westminster Palace Hotel. "Coal-Conveying Machinery," by C. H. Fletcher (member).

King's College Engineering Society.

March 6, 4 p.m.—At King's College, London. "Aluminium Extraction," by Mr. Hackman.

March 13.—Lantern slides.

Royal Institution of Great Britain.

March 6, 9 p.m.—Mr. A. R. Binnie on "The Tunnel Under the Thames."

March 7, 3 p.m.—At Albemarle-street, Piccadilly. "Light," by Lord Rayleigh, F.R.S. (third lecture).

HIGH-VOLTAGE LAMPS, AND THEIR INFLUENCE ON CENTRAL-STATION PRACTICE.*

BY G. L. ADDENBROOKE, MEMBER.

In the spring of 1891, which was the last occasion when the alternating *v.* continuous current controversy came prominently before this Institution, and when Mr. Crompton brought forward his feeder argument, I had the honour of opening the discussion, and subsequently continued the argument in the technical Press, besides going into it privately with Mr. Crompton. I was not, however, convinced of the superiority of low-pressure direct supply, and on the old premises I remain unconvinced still; but I saw that the advantages of the two systems were in many cases very nearly balanced, and if one or other was ultimately to prevail it would probably be for some other reason than lay in the arguments which had so far been brought prominently forward on either side. It was, in my mind, useless to say that the two systems were each the best for certain situations, for how was the line to be drawn; or in some cases were we to have both systems in one town? Though a possible, this did not seem to me a desirable solution. The question is not merely an academic one. Hundreds of thousands of pounds are every year now spent on electric lighting, and that a large portion of this sum should be spent in a way that is not the best and most permanent is a serious matter. Besides this, as a consulting engineer, I found my position an unpleasant one. What was I to recommend to my clients; and if I halted between two opinions, what would my clients think of me? I regret that in these matters I have not the assurance of some gentlemen who, I understand, circularise all town councils, keep their own touts, and are prepared to give cut and dried verdicts without hesitation on engineering points which, I must confess, I approach with a certain amount of awe and misgiving, and a very serious sense of responsibility. Now, it struck me four years ago, as I daresay it did others, that as the two methods had been argued over so carefully without any definite conclusion being arrived at, probably some outside and fortuitous circumstance which neither side had taken account of would ultimately turn the balance one way or the other.

POSSIBLE SOURCES OF INFLUENCE ON CENTRAL-STATION PRACTICE.

I therefore made a careful survey of the field, and the only eventualities I could think of, or which seemed likely to have a very important bearing on the problem, were the following—viz., the introduction of (1) an altogether new form of lamp, (2) a cheaper material for mains than copper, (3) a high-voltage incandescent lamp, (4) a much more economical incandescent lamp of the present voltage, (5) an improved and much cheaper storage battery.

Respecting a new form of lamp: after having seen Tesla's experiments at the Royal Institution, and after having learnt privately the views of some of our leading investigators on the field which they opened, I must say, as a practical man, I did not see any immediate hope of commercial success in this direction, however interesting the results might be scientifically. As regards the chance of a cheaper conductor being forthcoming, I have dealt with this question at length in a recent article in the *Electrical Review*. Owing to the cheap rate at which aluminium can be produced, and will increasingly be produced in the future, and since the conductivity of aluminium is 56 per cent. that of pure copper of the same section, the chances of aluminium ultimately supplanting copper are strong, but the change will undoubtedly be a comparatively slow one. The possibility of this, however, points to a reduction in the price of conductors; and this, of course, would tell somewhat in favour of moderate pressures. Again, as even in moderate-pressure mains insulated with bitumen or other compounds the cost of insulating is twice the cost of the conductor itself in the sizes usually employed, it it quite conceivable that very important economies may be effected in this direction. It is obvious that improvements of this character would probably tell more in favour of moderate pressure than of high.

Having thus disposed of the conductor question, we come to the third and fourth alternatives I have mentioned as likely to influence central-station practice—viz., the introduction of a lamp of higher voltage, or a more economical lamp of the present current-voltage. When thinking over the matter in 1891, I saw that, as fairly good lamps of 8 c.p. for 100-volt and 110-volt circuits were being made, two of them could be put in series, and that we should get very simply a 16-c.p. lamp of 200 to 220 volts. This, however, involved giving up eight-candle lamps except two in series, which, as the charge for current was then usually 8d. per unit, was a serious matter, and again, as there were two filaments in each lamp, the breaking of either of which would spoil the lamp, this also introduced an important objection, particularly as the Ediswan monopoly maintained the price of lamps at 3s. 6d. for ordinary

* Paper read before the Institution of Electrical Engineers, February 27.

Digitized by Google

voltages, and could hardly be expected to supply lamps which would be more expensive to make, except at an enhanced price. The prospect of obtaining high-voltage lamps did not, therefore, at that time appear bright. Time has, however, brought about great changes in the lamp industry, due largely to the expiry of patents, which quickly led to numbers of good lamps being placed on the market at less than one-third the price formerly charged, and at the same time brought active and pushing competitors into the field. Two years and a half ago, finding some disposition abroad to adopt higher voltages, I drafted an article pointing out the enormous gain which would accrue in the distributing system if higher-voltage lamps were adopted, intending to send it to one of the journals. The question, however, then appeared somewhat problematical, and other business led to the article being put on one side. I did not, however, forget the matter, and last December year, finding that one or two firms were trying to introduce lamps of 200 volts, I looked over my draft again, and, having somewhat elaborated it, sent it to the *Electrical Review*. The article attracted the attention of Mr. Baynes, then of Bradford, and he wrote detailing his experience and the experiments he had made with high voltage. Since then the matter has advanced by leaps and bounds. Several lamp-makers are undertaking to supply 16-c.p. lamps of voltages up to 230 and even above; and not only this, but Mr. Stearn and one or two other makers are offering lamps up to this voltage of 8 c.p. also, and guaranteeing a fair economy. The lamps are also being offered at moderate prices. Low-tension central-station engineers have not been slow to perceive the facilities these lamps offer. In some cases they have been adopted publicly, and in other cases private experiments are being made on them with satisfactory results. I also hear from those manufacturers who are catering for the market that the demand for high-voltage lamps is steadily and rapidly increasing. The adoption of these lamps is, of course, somewhat in the tentative stage; but so much progress has been made, and the results attained so far are so good, that no one can doubt that in a year or two they will become a permanent institution. It may also be noted here that since this paper was sent in I see that Prof. Kennedy has considered the 230-volt lamp sufficiently sound to recommend the Town Council of Edinburgh to adopt it.

Concurrently with this development there has been a tendency towards the use of lamps of ordinary voltage but of higher efficiency, and I must say that until recently I have been unable to quite make up my mind which was the best of the two lines to work on—whether it would be better to use lamps of 100 voltage, and taking 2½ watts per candle-power, or lamps taking four watts per candle-power, with a voltage of 200 or 220. I think, however, the matter now admits of being argued out pretty clearly. By a reduction of current per candle-power, in the proportion of 2½ to 4, mains of a given capacity would do nearly double the amount of lighting with the same expenditure of energy. Energy in itself is very cheap, however, and any fair-sized central station could supply double the quantity of energy it is now doing at 1½d. per unit for the extra current, if this did not entail extra expense for extra mains. Now, by doubling the voltage, we reduce the size of the mains to one-fourth, other things being equal; consequently the mains for a station using 220-volt lamps consuming 64 to 70 watts per 16-c.p. lamp, to give the same percentage loss, would not be much more than half the size they would be if the station supplied 110-volt lamps consuming 2½ watts per candle-power, as the current would be nearly the same in both cases. As the cost of mains is such a very large proportion of the whole central-station cost, and as energy can be generated so cheaply, I am fairly confident that, even if a good 2½-watt lamp were obtainable, it would pay better to use 220-volt lamps taking nearly double the current. Conversations with lampmakers, and recent publications on the subject, have convinced me that a good 2½-watt lamp of 100 volts has yet to be attained, and will probably be a very difficult thing to achieve, unless absolutely even pressures in the mains can be guaranteed. The opinion of lampmakers appears universally to be that a 220-volt lamp at 3½ to 4 watts per candle-power is a more practicable and attainable object than a 100-volt lamp at 2½ watts. They seem also unanimous that if a good 2½-watt 100-volt lamp could be made, a good lamp of 220 volts, and of better efficiency than four watts, would be forthcoming. It therefore appears that by taking a 220-volt lamp now we shall get all the advantages of high voltage, and in time shall get nearly as efficient a lamp as if a lower voltage were used, while the high-efficiency lamp is even now in a far less forward state of development than the high-voltage lamp. Consequently, it seems clear that the high-voltage lamp is the better line of the two at present. Besides this, we are anxious to cheapen the cost of current so that it may also be available for power purposes, and thus small economies in consumption will be of less and less moment. It is, therefore, obvious that not only in the present, but for the future, the high-voltage lamp is likely to be the better, and that it is safe to run the risk of being unable to use very economical lamps, provided decent ones of high voltage can be obtained.

As I thought it would give a practical basis to this paper, and would be of interest to members to see specimens of some of the various high-voltage lamps which are being made, I have written to leading makers on the subject, and through their kindness am able to submit a number of 220-volt lamps, concerning which I will now give the particulars supplied by the makers. Lamps to be arranged to burn; present data from makers, etc.: I shall not pursue this branch of my subject further, as it would be more suitably dealt with by a lamp manufacturer in a special paper; but I think enough has been said, coupled with the knowledge members already have of the subject, to show that high-voltage lamps are thoroughly practical for central-station work, and I therefore pass on to consider how far it is desirable to use them, and what effects they are likely to have on central-station practice—this being more immediately the subject of my paper.

Life of High-Voltage Lamps.

We can, of course, hardly expect the life of these high-voltage lamps to be as long as that of lamps of half the voltage, while at the same time they will be rather more expensive, consequently there will be a greater expenditure for lamp renewals when they are used; and it is advisable, I think, to try and arrive at a figure for this before proceeding further. If the life of an ordinary 16-c.p. lamp of 100 volts is 1,200 hours, and it consumes 64 watts, during its life it will consume 77 B.T. units, which, at 6d. per unit, amounts to 38s. 6d. If the cost of the lamp is 1s. 3d., its cost per unit of current consumed is 0·2d., or 1·5d., or about 3 per cent. of the cost of the current. For an eight-candle lamp of 100 volts, lasting 800 hours and taking 36 watts, the consumption of current is 29 units; and at the same price for lamps, the lamp cost per unit of current consumed is about 0·5d., or ½d., or about 8 per cent. of the cost of the current. I have assumed the above life for these lamps because I think, after burning the number of hours indicated above, most lamps would be best thrown away; though I am perfectly aware lamps often last twice as long as I have assumed, and they can also be purchased for 20 per cent. less from reliable makers. Two hundred-volt or 220-volt lamps will, of course, cost rather more, and their life would be rather less, but I believe I am putting the case more adversely for the higher-voltage lamps than is really true in taking the cost as double the above rates for lamp renewals where high-voltage lamps are used. The cost of lamp renewals would then be 6 per cent. of a customer's bill if the current was 6d. per unit for 16-c.p. lamps, and 16 per cent if 8-c.p. lamps were used. Supposing the number of 16-c.p. lamps installed to eight-candle lamps is about as 1 : 2—which is, I think, about a fair average—an all-round reduction of 6 per cent. in the charge per unit of current would cover the additional cost of lamps, if lamps of high voltage were used; at 6d. per unit for current, this is about one-third of a penny per B.T. unit. Such figures as these can only be approximate, but I think you will agree that they would not be far out in practice, and may be improved upon, and also that they make it clearly manifest that the extra cost of using high-voltage lamps offers no appreciable bar to their introduction, providing that their other countervailing advantages are in excess, with which branch of the subject I will now deal.

(To be continued.)

THE PHYSICAL SOCIETY.

At the ordinary meeting on February 28, Prof. John Perry, vice-president, in the chair,

Sir D. Salomons showed some experiments with incandescent lamps. A large electromagnet is excited by means of a continuous current while an alternating current is passed through an incandescent lamp. On bringing the lamp near the magnet the filament is set in vibration, which, if the lamp is brought sufficiently near the magnet, is sufficiently intense to break the filament. The number and position of the nodes formed in the vibrating filament are found to be independent of the natural period of the filament, but depend on the frequency of the alternating current.

Prof. S. P. Thompson asked whether it was not found that the number of segments into which the filament is divided depended to some extent on the natural period of the filament.

Prof. Ayrton said that the magnetic leakage was very large with the arrangement adopted, and he would like to know whether this method was a more sensitive one for mapping out the field than those ordinarily employed. In an instrument designed by Prof. Perry and himself an alternating current was passed through a wire stretched between the poles of a magnet, and the tension of the wire was altered till the vibrations set up were a maximum. The natural period of the wire, and hence the frequency of the alternating current, was then deduced from the tension, etc. In Prof. Ewing's magnetic curve tracer, on the other hand, the natural period of the stretched wire was made as different as possible from the period of the alternations which were to be observed, so that the natural vibrations of the wire did not

Digitized by Google

influence the results. The author's arrangement appeared to him (Prof. Ayrton) to be intermediate between these two, and it would seem that the natural period of the filament would to a certain extent influence the results.

Prof. Perry suggested that the lamp might be held in a very steady support so that after the large vibrations due to the natural period of the filament had died out the vibrations of the period of the alternations alone could be observed.

Sir D. Salomons in his reply, said that the arrangement was not intended for making measurements. A lamp had been fixed in a steady clamp, and the current passed for many hours, but the character of the vibrations remained unaltered He had found the vibrating filament useful for microscope work, where a surface rather than a line of light was required.

Prof. Fleming read a paper by himself and **Mr. Petavel** on **"An Analytical Study of the Alternating-Current Arc."** The first part of the paper consists of an analytical study of the distribution of light throughout the various radiating regions in the arc when supplied with electric power of known constant amount, the periodic variations of the current through the arc and of the potential difference between the carbons being at the same time recorded. The power was measured by means of a bifilar watt-meter, while by means of a series of mirrors and a rotating disc carried by a synchronising alternate-current motor the mean value of the light taken from any part of the arc was compared with the instantaneous value of the light taken from the same part of the arc, and taken at any assigned instant during the period. Thus the arc itself was its own standard, and difficulties due to slow variations in the mean light of the arc disappear. The facts observed may be summed up as follows: The purple light of the true arc undergoes a periodic variation, and, as far as the eye can judge, is completely extinguished during a certain interval during the phase. It has equal maxima values during the period at instants slightly lagging behind the instants of maximum power expenditure in the arc. On the other hand, the illuminative power of the carbon crater varies between a minimum value and two unequal maxima, the greater maximum occurring when the carbon is positive and an instant slightly lagging behind the instant of maximum power expenditure in the arc. The second part of the paper consists of a comparison of the efficiency of the alternate-current arc regarded as a light-giving agent as compared with that of a continuous current arc taking the same mean power. Using two arcs, which may be regarded as typical of those used in practice, the mean spherical candle-power was compared for equal expenditure of power in the arcs, and it was found that for the alternating-current arc employed the total mean spherical candle-power was always less than that of the continuous current arc. Lowering the frequency seems to decrease the efficiency of the alternating-current arc.

Prof. Ayrton said the behaviour of the alternate-current arc was of great interest, for the power supplied could not be measured by simply multiplying the current by the E.M.F., since the current lags behind the volts. The resistance—*i.e.*, the ratio of the current to the E.M.F.—also lags, but the authors do not appear to have made any attempt to measure the true resistance The authors were to be congratulated on the guarded tone they had adopted as to the bearing of these experiments on the question of the relative efficiency of the alternating and continuous current arcs. In a previous communication, one of the authors had stated that the alternating-current arc must necessarily be a less efficient light-producing agent than the continuous-current arc. Although the last set of curves given in the paper might appear to support this supposition, he (Prof. Ayrton) felt that the difference obtained was probably due to the fact that the alternating-current arc was not being worked under proper conditions. The quality of the carbons and the length of the arc have a most important influence on the efficiency of an arc At present our knowledge is not sufficient to allow of our stating definitely whether or not an alternating-current arc can be made as efficient as a direct-current arc, but there is no doubt that it will be possible to get much better results than are at present attainable.

Prof. S. P. Thompson said that when the fact of the existence of the difference in phase between the current and volts in an alternating arc was first published he had made some experiments, which showed that there was a lag and not a lead—*i.e.*, that the arc acted as if it possessed self-induction. The resistance also lagged, and he thought this lag might be due to a thermal lag. The temperature of the arc will lag behind the current, both when it is increasing and when it is decreasing, and if the resistance of the arc depends on the temperature of the vapour in the arc then the resistance would also lag behind the current. It was not possible from *à priori* reasoning to say whether or no an alternating-current arc could ever be obtained of an efficiency equal to that of the direct-current arc. With suitable carbons, length of arc, current, and volts it seemed to him that it might be possible to obtain an equal efficiency. The light-giving process in an arc is not merely an irreversible degradation of electric energy into heat, for the difference of potential between the carbons may be written $V = a + bl$, where a may be regarded as a back E.M.F. and bl as a true resistance The first term of this expression does not vary with the length of the arc, l, but the second term does. Multiplying through by the current, C, the equation, watts expended $= Ca + Cbl$, is obtained. It is the first of the terms on the right-hand side which is a reversible effect, and corresponds to the power expended in driving the current against a back E.M.F. on which the light given out chiefly depends due to something occurring at the crater surface.

Mr. Blakesley asked whether Prof. Thompson's idea of the light being due to the reversible part of the process was not a strong argument in favour of the direct-current arc.

Prof. Ayrton said that in two communications made to the congress held at Chicago it was shown that even with direct-current arcs there was a certain length of arc for which the efficiency was a maximum. Mrs. Ayrton had quite recently found that the efficiency of arc lamp carbons altered with time. Prof. Thompson's suggestion as to a thermal lag was a valuble one.

Prof. Fleming, in his reply, said that when comparing two agents where there were so many variables it was practically necessary to restrict the investigation In their case they had kept the mean power constant and had left the other variables to take care of themselves.

The society then adjourned till March 13.

CITY OF WORCESTER.

The following is an abstract of the Corporation electric light accounts for the year ending December 31, 1895, which have just been published, together with a report by the city electrical engineer:

Dr. Capital Account.	£	s.	.
Lands, including law charges incidental to acquisition	5,182	8	8
Buildings	19,706	16	6
Machinery, Mains, including the cost of laying the mains and services, Transformers motors, etc	25,111	7	3
Meters	1,154	17	6
Electrical instruments, etc.	212	17	2
General stores (cable, mains, lamps)	214	15	2
Preliminary expenses	504	7	3

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

Quantity generated in B.T. units.....		348,251
Quantity sold—		
Public lamps.....	33,890	246,912
Private consumers by meter.....	213,022	
Quantity used in works		8,955
Total quantity accounted for.....		255,867
Quantity not accounted for		92,384
Number of public lamps—27 arc lamps of 500 watts each, six incandescent lamps of 112 watts each.		
Total maximum supply demanded (kilowatts)		432·7

REPORT ON THE ELECTRICITY DEPARTMENT'S WORK IN 1895 BY MR. E. T. RUTHVEN-MURRAY.

In order that you may better realise the result of last year's working, I have analysed the return and accounts in such a manner that a comparison may be made between our own figures and those published by other electricity supply stations, and in making these comparisons the charges for interest and sinking fund have been excluded. Taken as a whole, our total costs figure of 2·97d. per unit sold is decidedly satisfactory, although it is higher than I anticipated. Nevertheless, if the average price obtained, 3·163d., were not so extremely low, we should have made a substantial profit. Undoubtedly the figure in the cost which looks out of proportion is that of 1·06d. per unit sold for fuel; and in the reduction of this figure I see most hope of lowering the cost of generation in future. There are several reasons why this figure is so large, and pre-eminent is the fact that the available water power did not come anywhere near its calculated value, with the result that from the end of May until the end of November it was necessary to run a portion of the day on steam only. About Midsummer there was so little water in the Teme that as much as 75 per cent of a total week's running hours were done on steam power. As the engines at the works are all of 286 i.h.p., we had no choice but to run these at the very low load which was the maximum that could be obtained, and at a load-factor so small that high efficiency and low consumption of steam, and therefore of fuel, was impossible. A condenser was thought unnecessary when the works were equipped, but this omission is now made good, and will, I have no doubt, effect an economy in the steam consumption of the engines of upwards of 20 per cent. Before it became necessary to run by steam power in the daytime, we were using Staffordshire coal entirely, but in consequence of repeated complaints about smoke, you instructed me to burn Welsh smokeless coal when found necessary, which, being considerably more expensive, is an important factor in the cost of fuel. The reason for so much coal being used was to keep running for the electric pumping plant at the waterworks. I estimate that not less than 400 tons of coal were used entirely to keep one motor running during the summer. As the price we received from the Water and Sewerage Committee was only 1d. per unit, it will be seen that over the whole year our costs show a higher figure than this for coal alone, and instead of making anything out of the day load found by these motors, you have actually lost money by having them on circuit. During the summer the contractors were engaged in replacing the coils of the alternator armatures with others of improved type, and to test them it was necessary to run the machines for many hours continuously. As no water power was available, steam had to be used, and testing accounts for some 80 tons of coal It is authoritatively stated that the past summer was one of unusual drought; therefore we may not be so short of water during the coming season. We have recently improved the figure for cost of engine-room stores, by alteration of the lubricating arrangements on the machinery at the works Of the figure ·267d. per unit, ·156d. is engine-room stores. The figure of ·111d. for carbons is not a true result of the year's working, as the carbons used during the few months of last year were altogether omitted, and have been added here We are now purchasing carbons at about 22 per cent less than we were during last year, and in the next report the figure of ·267d. per unit will be materially reduced. The next figure of 1·088d. per unit for wages at works is low for the character of the station, and cannot be reduced except in so far as it will be from the larger output we may expect this year. It is apparent that this will fall proportionally as the output rises. The same remark applies to the figure for repairs and maintenance, which I do not anticipate will much increase. The figure which includes legal expenses, management, and insurance may be altered other than proportionally, although the figure for rates, taxes, and rents should share in the reduction from increased output. Turning from costs to revenue, the most striking item is that of the average price obtained, which, excluding revenue derived from meter rents, property rents, etc., only amounts to an average of 2.73d. per unit, a figure without parallel in the annals of the electricity supply business, The figure, including revenue from other sources, 3·16d., is lower than any recorded. The waterworks motors are again mainly responsible for these figures. They were supplied with 103,644 units, for which we received the sum of £431. 17s. This number of units bears the relation of 41·9 per cent. to the total output of 246,912 units. For the remaining 58·1 per cent. (143,268 units) we received £2,386. 8s. 2d., or an average of 3·99d. per unit, a figure above the lowest on record of other stations. Bearing in mind the unusual difficulties we have had to engage with and overcome during the past year, our results cannot but be considered satisfactory. The number of lamps we have taken on is very gratifying, amounting to an increase of over 200 per cent., and I have no doubt, from information received, that we shall have a large accession of small consumers, from whom we derive a much better revenue per lamp than from most of the larger ones during this year.

WATER AND STEAM POWER.—The following table shows the percentage of hours running by water and steam power during the past year:

	January to June.	July to December.	Whole year.
Water alone	85 per cent.	49 per cent.	67 per cent.
Steam alone	10 ,,	40 ,,	25 ,,
Water and steam	5 ,,	11 ,,	8 ,,

BRISTOL CORPORATION ELECTRICITY WORKS.

The accounts have been issued of the working of the electric light station of the Bristol Corporation during the year ended December 31, 1895. The expenditure during the past year reached £15,608. 8s. 5d., and the total expenditure to December 31, 1895, has amounted to £97,794. 11s. 10d. Below are given the revenue account and balance-sheet.

REVENUE ACCOUNT YEAR ENDING DEC. 31, 1895.

Dr. To Generation of Electricity.				£	s.	d.
Coal or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	£1,616	1	9			
Oil, waste, water, and engine room stores	156	9	3			
Wages at generating station.....	1,178	3	0			
Repairs and maintenance as follow: buildings, £12. 18s. 8d.; engines, boilers, etc, £81. 1s. 10d.; dynamos, exciters, etc., £1. 10s. 3d; condensers, other machinery, instruments, and tools, £70. 15s. 8d.; accumulators and accessories, £22. 10s. 1d.	188	16	6			
Removing ashes	35	0	0			
				3,174	10	6
To Distribution of Electricity.						
Wages and other remuneration to linesmen, fitters, labourers	80	4	10			
Repairs, maintenance, and renewals of mains of all classes, including materials and laying same, £58. 8s. 10d.; less amounts chargeable to contractors, £34. 2s 1d.	24	6	9			
Repairs, maintenance, and renewals of transformers, meters, switches, fuses, and other apparatus on consumers' premises, together with cost of lamps sold, as *per contra* ...	35	1	4			
Repairs maintenance, and renewals of apparatus at distributing stations	51	8	0			
				191	0	11
To Public Lamps.						
Attending and repairs	367	7	0			
Carbons and renewals of lamps	143	14	5			
				511	1	5

* This item covers one-third of the quantity used in the day time which is unable to be ascertained, owing to the description of clock meter used by day-load consumers, as well as the ordinary loss in mains, transformers, instruments, etc.

LEGAL INTELLIGENCE.

CLAIM FOR ELECTRICAL WORK.

At the Westminster County Court on Tuesday, before his Honour Judge Lumley Smith, Q.C., the case of Sabow *v.* Haynes was heard.

The plaintiff's claim was for a balance of account amounting to £10. 16s. 2d. in respect of electrical fittings supplied and fixed to defendant's order. In his evidence, the **Plaintiff** said he carried on business at Fulham, and in the early part of 1895 he got instructions from the defendant to supply and fix a quantity of electrical fittings. The work was completed in July, and a portion of the amount due was paid on account, but for some reason or other the defendant declined to pay the balance, and set up a counterclaim for damages for defective work.

The **Defendant** admitted that there was a balance due to the plaintiff, but he contended that he was not liable on the ground that the work was so badly done as to be absolutely useless.

After hearing the evidence, his **Honour** said he was by no means satisfied with the defendant's story, and gave judgment for the plaintiff on claim and counterclaim.

COMPANIES' MEETINGS AND REPORTS.

CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.

The annual general meeting of this Company was held on Wednesday at the Company's central station, Cadogan-gardens, Mr. J. Irving Courtenay presiding.

The **Chairman**, in moving the adoption of the report and accounts, a copy of which has appeared in this journal, said last July they lowered the charge for current by 25 per cent., and consequently the increase in revenue might not seem so large as might have been expected. They were enabled to recommend the same rate of dividend on the ordinary shares—5 per cent.—as that paid last year, they had placed £1,047 to a reserve fund, and they proposed to carry forward £1,114. They had again reduced the cost of production. They had had a considerable increase—over 10,000—in the number of lamps supplied, and this increase was still going on, and even to a larger extent. The continued expansion of the business created a recurring need for fresh capital, for they only raised additional capital and increased their plant and mains from time to time as wanted. During the past year they had completely altered and equipped the new generating station in Manor-street, and a new storage station for the supply of the Fulham road district would shortly be completed. An injunction had been granted against the Company in respect of the generating station at Cadogan-gardens, but he hoped they would shortly be in a position to deal with this troublesome matter in a manner which would put an end to further litigation. The electric light supply companies carried on a *bonâ fide* and necessary business, and with, as yet, only moderate returns to their shareholders. They had statutory duties to fulfil, and, in his opinion, without adequate legal protection, and they were considered as fair game to be shot at, the alternatives generally presented to them being either to purchase peace at any price which the occupier of an adjoining property chose to demand, or to run the risk of being forced to discontinue the full use of premises upon which a large capital had probably been spent.

Major-General Webber, C B. (deputy chairman), seconded the motion, which was carried unanimously.

HOVE ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Colonel A. J. Filgate, R.E. (chairman); Colonel H. Wood, C B. (vice-chairman); Harold A. Hoare, Esq.; Carleton F. Tufnell, Esq. Engineers: Messrs. Crompton and Co., Limited. Secretary: Francis R. Reeves, Esq.

Fourth report of the directors presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon-street, E.C., on Wednesday, March 4, 1896, at 12 o'clock noon:

The number of lamps attached to the Company's mains has now increased to the equivalent of 18,403 8-c.p. lamps, and the number of consumers to 270. From the accompanying statement of accounts it will be seen that the result of the year's working is a profit of £2 562. 5s. 3d. as compared with £1,243. 0s. 5d. for the preceding 12 months, and it is satisfactory to report that the consumption of electricity per lamp fixed has increased rather than diminished, as compared with the consumption of the preceding year. The revenue from the sale of current has increased from £3,616 19s. 9d. in 1894 to £5,343 6s. 9d. After adding £15. 12s 9d. from last year's accounts, and deducting £1,038 12s. 7d. for interest on loans and debentures, there remains a balance to the credit of net revenue account of £1 539. 5s. 5d. The directors propose to write off the sum of £134. 15s. from the preliminary expenses account, to place £200 to reserve, to declare a dividend at the rate of 4 per cent. per annum on the share capital, payable on April 15 next, and to carry the balance £152. 14s 6d. forward. The amount realised from premiums on shares and on the 4½ per cent. debentures which were issued last year was £460. 10s.; this has also been placed to the reserve fund, which will now show a credit balance of £660. 10s. In accordance with the contract with the Hove Commissioners, the sum of £263. 9s. 2d. has been also placed to a depreciation and maintenance reserve account. Since the date of the last report the directors have placed 1,719 shares and £7,500 of 4½ per cent. debentures. Offers were received for the balance of the 4½ per cent. debentures at the issue price of £103, but the directors considered it advisable to place no more than the £7,500 at that time. The total number of shares issued to date is 6 260, representing £31,300, and the directors now offer the balance of 1,740 shares to the proprietors for subscription at £5. 5s. per £5 share. As the Company has been placed in a sound position, both financially and as a dividend-earning enterprise, the directors have given notice to the holders of the £12,500 of 5 per cent. debentures that they intend to pay off the same on July 1 next, and have offered to them new debentures of the Company at par bearing 4 per cent. interest in exchange. In response to the circular making this announcement, the holders of £7,250 of debentures have agreed to accept the new 4 per cent. debentures, thus leaving £5,250 to be placed, and the directors entertain no doubt of their ability to place these in July next, when the existing debentures are to be paid off. Owing to the proximity to the sphere of this Company's operations of the Brighton Corporation electric supply works, where the management are not under the same obligation as are the directors of a public company to work for substantial returns upon the money invested, and, in consequence, are able to make a low charge for their production, an adverse comparison has been made between the charges made by the Brighton Corporation and by this Company. The Board, desirous of doing everything in their power to meet the wishes of their customers, have adopted, as from January 1 of the present year, the method obtaining in Brighton of charging by the "demand meter" system, which regulates the rebates or discounts allowed to customers in accordance with the actual consumption calculated upon the maximum number of lamps in use at any one time. This arrangement of charging is, they consider, as fair a one as can be devised and the directors hope that as the system offers inducements to consumers the change will result in a considerable increase during the year in the number of lamps fixed, and a corresponding increase in the consumption of current. The directors have pleasure in again congratulating the shareholders upon the position and progress of the Company. The supply of current has been regular and continuous throughout the year, and the machinery, which is maintained in the highest degree of efficiency, has given the greatest satisfaction. In order to meet the increasing demand for electric

Digitized by Google

current in Hove, the directors were obliged last year to add a new Crompton-Willans set of 250 h.p., and two new boilers. With these additions to the plant, it is believed that the Company will be able to meet the demands likely to arise for some time to come. Mr. C. F. Tufnell retires from the Board by rotation, but offers himself for re-election. Mr. Robert Payne, F.C.A., auditor of the Company, also offers himself for re-election.

W. T. HENLEY'S TELEGRAPH COMPANY, LIMITED.

The annual report has been issued, and shows that a net profit has been made of £21,823. 19s. 5d. After payment of debenture interest, and income tax, and making an allowance for depreciation of plant, machinery, etc., there remains £17,342. 9s. 2d., to which must be added £1,600. 7s. 9d., the final dividend received from the International Cable Company, Limited, and £8,624. 9s. 3d. brought forward from last year, making a total of £27,567. 6s. 2d. From this must be deducted £2,100, the interim dividend of 3 per cent. paid on the ordinary shares on August 1 last, and £1,050, the half year's dividend on the preference shares paid in October, and there remains a balance of £24,417. 6s. 2d. Of this sum the directors have transferred £5 000 to reserve fund, and they propose the payment of the remaining half-year's dividend on the preference shares at the rate of 7 per cent. per annum, and a further dividend of 5 per cent. free of income tax on the ordinary shares (making a total distribution of 8 per cent. for the year, free of income tax, on the ordinary shares). These payments together absorb £11,050, leaving £13,367. 6s. 2d. to be carried forward.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

Admiral Sir G. H. Richards presided over the ordinary meeting of this Company, held on Tuesday at 38, Old Broad-street, and moved the adoption of the report. He said there had been very little submarine telegraph work done during 1895, but a great portion of that carried out had been executed by the Company. The total dividend for the year was at the rate of 15 per cent. per annum. The Company was never in a sounder financial position than now, while the prospects of work for the coming year were more favourable.

Sir R. G. W. Herbert seconded the motion, and it was carried unanimously.

ISLE OF MAN TRAMWAYS COMPANY.

The annual general meeting of the Isle of Man Tramways and Electric Power Company, Limited, was held at Douglas last Friday, Mr. Alexander Bruce presiding.

The **Chairman**, in moving the adoption of the report and accounts, said that the balance-sheet showed the total takings to be £26 466 and the expenses to be £11,999, leaving an actual profit for the year of £14,467, which placed them in a unique position compared with any similar undertaking in the kingdom With the balance from last year, the sum available was £15,789. Debenture interest at 6 per cent. and a half-yearly dividend at the rate of 7½ per cent. was paid in June, leaving £10,227 to be dealt with by the meeting. Out of this the directors proposed to add £2,000 to the renewal and reserve fund, had paid £1,299 on debenture bonds, and proposed to pay a dividend at the rate of 6 per cent on the preference shares and on the ordinary stock at the rate of 8½ per cent., absorbing £4,687, making the dividend for the year 8 per cent. on the ordinary stock, and leaving £2,240 to be carried forward.

The report and accounts were unanimously adopted, and Dr. Farrell and Mr. Pittar were re elected directors.

After the general meeting, an extraordinary meeting was held, and a resolution was adopted to take over Snaefell Mountain Electric Railway at £72,500.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Aberdeen.—The Corporation invite tenders for an additional engine of 300 h.p. at the electric lighting station.

Erfurt.—Tenders are wanted by March 11 for the supply of 52,000 carbons for arc lamps for the Prussian State Railways at Erfurt.

Naples.—Tenders are wanted by March 9 for 3,500 kilogrammes of copper wire. The estimate is 6,475 lire. Address, La Fonderia reale, Napoli.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, Avenue Hoche 8, Paris.

Namur.—Tenders will be received on July 10 next for the construction of a telephone building at Namur. Plans and particulars can be obtained from le Service Téléphonique, Namur.

Duisburg (Germany).—The Municipality require tenders before March 23 for the electric lighting work for their new swimming-bath. Particulars can be obtained for 2 marks (2s.) from the Stadtbaurath, Duisburg.

Zamora (Spain).—The electric lighting of the town of Zamora for 20 years is offered for tender. Conditions are obtainable at the Ministero de la Gobernacion, Madrid, and la Casa consistorial, Zamora. A security of 4,000 pesetas (£160) will be required.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of apparatus for electric alarm bells. Tenders, suitably endorsed, must be sent to the Chief Engineer, at the Company's Stores, Santa Apolonia, Lisbon, by March 11, and particulars, etc., can be obtained from the Paris Offices of the Company, at 28, Rue de Châteaudun.

Christiania.—Tenders are wanted for the supply of telegraphic instruments, including 26 Morse apparatus, 11 galvanometers, and three signal bells, paper tape, etc., for the Norwegian State Railways. Tenders must be sent in by March 11 to the office, Iernbanctorvet 8-9, and particulars can be obtained of the Inspector of Telegraphs, Ostbahnstation, Christiania.

Pontefract.—The Guardians invite tenders for fitting up the new infirmary with electric bells. Full particulars may be obtained on application at the offices of Messrs. J. Holmes Greaves, and Co., architects, 38, Albion-street, Leeds; Corn Market, Pontefract. Sealed tenders, on proper forms, to be delivered at the Union Offices, Pontefract, by 6th inst., at 4 p.m., endorsed "Elec ric."

Digitized by Google

Bucharest.—The authorities of the city of Bucharest require tenders for some system of lighting the suburbs which does "not require to be conveyed underground by pipes or otherwise." Particulars can be obtained at the Agence Havas, 96, Queen-street, Cheapside, E.C., and tenders will be required by March 26.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange-town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Glasgow.—Tenders are required by the Corporation for a compound dynamo machine for the sewage purification works, Dalmarnock. Specifications and forms of tender may be had on application to Mr. Thomas Melvin, manager at the works, and tenders, properly sealed, and marked outside "Tender for Dynamo Machine," must be lodged with Mr. J. Lang, clerk, City Chambers, Glasgow, by 14th inst.

London, S.W.—The Guardians of Chelsea invite tenders for the supply and fixing of telephones and communications with certain wards and rooms of their infirmary in Cale street, in accordance with a specification which may be obtained, and samples of the instruments and fittings which may be seen, at their offices, 250, King's-road, Chelsea. Tenders must be delivered at the Guardians' offices by noon on March 10.

Paris.—The Direction générale des postes et des télégraphes, rue de Grenelle 103, Paris, require tenders for the supply of 10-millimetre and 16 millimetre paper tape for telegraphic instruments. Application for permission to tender must be made to the Direction by March 14, and tenders sent in by March 24. Tenders are also wanted for nine lots of apparatus for telegraphic offices. In this case application must be made by March 15, and tenders sent by March 25.

Leeds.—The Electric Light Company invite tenders for the various works required in the extension of the electric light station in Aire street, Leeds. Plans and specifications at the offices of the company, Aire-street, and bills of quantities on application to Messrs. Milnes and France, architects, 99, Swan-arcade, Bradford, on 12th inst. and until 19th inst., on which latter day sealed tenders, properly endorsed, are to be delivered to the architects by 6 p.m.

Herne (Germany).—It is proposed to make a street railway nine kilometres (5½ miles) long from Herne to Recklinghausen, to be worked either by gas motors or electric traction. The undertaking will be put out to general competition, and the contractor will have to covenant for its completion in from one to five years. Tenders must be sent in by March 18, and particulars price 1 mark (1s.), can be obtained from Herr Amtmann Schaefer, Der Verwaltungsausschuss Herne.

Manchester.—The Manchester, Sheffield, and Lincolnshire Railway Company invite tenders for the supply, during twelve months ending April 30, 1897, of telegraph materials. Patterns can be seen on and after March 9, on application to Mr. A. W. Longden, storekeeper, at Junction-street Mills, off Ducie-street, London-road, Manchester; and specifications, with forms of tender, may be obtained on and after same date, from Mr. Oliver S. Holt, secretary, London-road Station, Manchester. Applicants are requested to particularise the stores for which they wish to tender. Sealed tenders, endorsed "Tender for ——," to be in the hands of the secretary by 10 a.m. on March 17.

Chesterton (Cambs).—The Urban District Council is open to receive tenders for the public lighting of the district for seven years. The tenders shall be made in the three following modes—namely, (*a*) lighting the district from August 14 to May 15 (inclusive) in each year; (*b*) lighting the district throughout the whole year commencing May 15 next; (*c*) lighting the district for either of the above periods (1) with ordinary burners, (2) with incandescent burners, if the illuminant with which the tender be made be gas. All cleaning, lighting, and maintenance to be done by the contractors. Tenders to be sent to Mr. James Spearing, clerk, 15, Sydney-street, Cambridge, by March 31.

Sunderland.—The Corporation want tenders for the following plant required at the electric supply station: (*a*) two steam-engines and continuous-current dynamos, with steam and exhaust pipes and switchboard extensions; (*b*) two water-tube boilers of Babcock and Wilcox type; (*c*) fuel economiser; (*d*) a water-softening plant; (*e*) a cast-iron tank. Specifications, general conditions, and form of tender can be had at the office of the borough electrical engineer, electric supply station, Sunderland, on payment of a deposit of £1. 1s. for each of the above. The deposit will be refunded on the receipt of a bona fide tender. The tenders will be let subject to the consent of the Local Government Board to the application of the borough of Sunderland for the extended loan for the above works. Tenders to be delivered at the office of Mr. Fras. M. Bowey, town clerk, Town Hall, Sunderland, by 5 p.m. on March 13, addressed to the Chairman of the Highways Committee, and endorsed "Tender for Extension of Electric Supply Station."

Bangor.—The Corporation invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough. The contract will be split up into two sections: (1) construction, supply, and erection of boilers (water-tube), steam-engines (double acting), steam and exhaust pipes, etc., economiser, feed pumps, condenser, alternators, exciters, accumulators, switchboard, travelling crane; (2) supply and laying down of mains and transformers. Specifications and plans may be obtained on payment of £2, 2s. for the former and £1. 1s. for the latter, which will not be returned, at the office of Mr. F. Hastings Medhurst, M.I.E E., Westminster-chambers, 13, Victoria-street, S.W., on and after 24th inst. The firm whose tender is accepted will be required to enter into a contract and a bond with two approved sureties for the due performance of the contract. Firms may tender for one or both sections, but tenders for a part only of either section will not receive consideration. Sealed tenders, endorsed "Electricity," to be delivered at the office of Mr. W. H. Pritchard, town clerk, Bangor, by March 18.

RESULTS OF TENDERS.

Alexandria.—The concession for the electric tramways at Alexandria has been awarded to Mr. P. Cauderay, Paris, on the basis of an annual payment of £58 per tramcar run.

Blackpool.—The Corporation have accepted the tender of Messrs. John Fraser and Son, of the Millwall Boiler Works, London, for the supply of two boilers, and all fittings included in Section A of the specification, and also the whole of Section C of the specification for evaporative condensers. The tender of Messrs. S. Z. de Ferranti, of London, for the supply of one 300-kilowatt alternator and two rectifiers, and the tender of Messrs. Tinkers, of Hyde, for the supply of pipe work, were also accepted.

BUSINESS NOTES.

Manchester.—The Tivoli (Folly Theatre) is to be redecorated and lighted with electricity.

Cardiff.—The Lighting Committee have agreed to contribute to the cost of lighting the arcade.

Western and Brazilian Telegraph Company.—The traffic receipts for the past week were £2,624.

Brompton.—The whole of the buildings at the Hospital for Consumption have been lighted by electricity.

Wells (Somerset).—The Town Council are about to apply for sanction for a loan of £10,000 for electric lighting.

Plymouth.—The Chamber of Commerce has held a meeting in support of telegraphic communication with lighthouses.

Leeds.—It is proposed to erect two new arcades in New Briggate, which will be completely fitted with the electric light.

Faversham.—The electric light station at the works of the Cotton Powder Works Company, Limited, has been destroyed by fire.

Eastern Telegraph Company.—The receipts for the month of February were £69,711, as against £62,342 for the corresponding period of 1895.

Kilmarnock.—A party of Messrs. Grant, Ritchie, and Co.'s men have visited the Ballochmyle Quarries and inspected the electric lighting there.

Bridlington.—The electrical engineer to the Urban Council has been instructed to have the Prince's-parade lighted by electricity during the Easter holidays.

Bangor (N. Wales).—The Town Council have confirmed the action of their committee in advertising for tenders in connection with the electric lighting scheme.

Salford.—The Town Council have decided to apply for the sanction of the Local Government Board to borrow £5,000 for requirements as to electric lighting.

Eastern Extension Telegraph Company.—For the month of February the receipts show an increase of £14,050 as compared with the corresponding period of 1895.

Swansea.—The Streets Committee of the Corporation have instructed the borough surveyor (Mr. Bell) to inspect the Swansea tramway lines and report on their condition.

West India and Panama Telegraph Company.—For the two weeks ended February 29 the receipts were £2,681, as against £1,947 for the corresponding period of 1895.

Portsmouth.—The estimate for the next rate shows an advance of some £3,500, one of the principal items being the cost of extending the street-lighting by electricity.

Halifax.—The Gasworks Committee of the Corporation have decided to recommend the Town Council to apply for sanction to borrow £20,000 for electric lighting purposes.

Salford.—The Gas Committee recommend the Borough Council to apply to the Local Government Board for sanction to borrow £5,000 for requirements as to electric lighting.

Aberdeen.—In view of the increased demand for the supply of electric current, it has been remitted to the electrical engineer to report as to an extension of the works and mains.

Worcester.—The Town Council have decided to lay mains in Bridge street, College-street, The Tything, and the road to Shrub Hill, for further electric lighting, at a cost of £1,000.

Newcastle-under-Lyme.—The Town Council have refused their consent to a deviation of the tramway from Stoke, and have decided to oppose the Bill for tramway extension to Newcastle.

Woolwich.—The Local Board of Health have agreed to the closing of Victoria-street, on the condition that Messrs. Henley's Telegraph Company provide a parish wharf 149ft. long and 40ft. wide.

St. Giles's (London).—The new public library just opened in New Oxford-street is lighted throughout by electricity, the fittings and installation being supplied by Messrs. Pontifex and Co., of Coleman-street.

Digitized by Google

Aluminium.—We have received from the Pittsburgh Reduction Company a copy of their treatise on aluminium. The book is published by the European agents of the company at 38, Victoria-buildings, Manchester.

Belfast.—The Corporation have received a deputation on the unsatisfactory state of the tramway service. In the course of the proceedings it was suggested that some form of mechanical traction might be adopted.

Brazilian Submarine Telegraph Company, Limited. — The directors have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum free of income tax, for the quarter ending December 31.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending March 1 amounted to £1,056, as compared with £934 in the corresponding week of the previous year, being an increase of £122

Tunbridge Wells.—An article by Mr. H. Boot, borough electrical engineer, has appeared in the *Kent and Sussex Chronicle* advocating the adoption of electric tramways by corporations possessing electric light stations.

Northwich.—The Northwich Electric Supply Company, Limited, was registered on February 24, with a capital of £10,000 in £5 shares, to carry on the business of electric lighting at Northwich, Leftwich, Davenham, and Hartford.

Liverpool Electric Supply (Transfer) Bill.—Under this Bill it is proposed that the borrowing powers be increased to £500,000, so as to provide capital for extensions. The town clerk has been instructed to assist the progress of the Bill.

Rose and Bird, Limited.—We are informed that Mr. A. H. Rose has joined this firm in the capacity of managing director, in place of the late Mr. J. A. Bird. The offices of the firm are now at Albany-buildings, 39, Victoria-street, S.W.

St. George's, Southwark (London).—The Vestry have decided to petition against the City and South London Railway Bill so as to obtain a *locus standi* in objecting to any of the shafts which the company propose to sink in the parish.

Derby.—In view of the approaching legislation on the subject of light railways, the committee in charge of the scheme for constructing an electric tramway between Derby and Ashbourne have decided to postpone further action for the present.

Cheltenham.—The Town Council have decided to apply for sanction to borrow £15,000 for electric light extensions. In reply to Major Cardew's report on the recent accident, the town clerk had written that the suggestions made had been carried out.

Bell's Asbestos.—The directors of Bell's Asbestos Company, Limited, have decided to recommend the payment of a dividend at the rate of 3 per cent. per annum, and the placing of £1,000 to the reserve fund, leaving about £2,200 to be carried forward.

Coolgardie (W. Australia).—The Westralian Electric Lighting and Supply Company have secured a monopoly for 21 years from the Municipality of Coolgardie. The company will also supply electric power to the various mines, and the town installation is almost completed.

Blackpool.—The Town Council have approved the proceedings of the Electric Lighting Committee recommending the application to the Local Government Board for further borrowing powers of £30,000 for new boilers and alternators and extensions to the electricity works.

Johannesburg.—It is stated that preliminary negotiations have been concluded for the establishment of an organisation in Johannesburg representing a number of large German manufacturers. The firms co-operating include the Union Electricity Company of Berlin.

Eastbourne.—At the meeting of the Town Council, Councillor Wright called attention to the cost of electric lighting, and asked how much per unit was paid to the company by the Corporation. Alderman Pocock believed it was 8d. per unit, but the Front was lighted under contract.

Bray (Ireland).—At a meeting of the Township Commissioners Mr. Harris, resident electrical engineer, forwarded a report on the machinery necessary to make the electric lighting station perfect; and Mr. Hammond, C.E., was appointed to make out estimates for the necessary repairs to the works.

City of London.—At the meeting of the Commissioners of Sewers Mr. Gordon asked when the experiments in the lighting of the side streets by electricity would be commenced, and Mr. Voysey, the electrical inspector, said it depended upon the City of London Electric Lighting Company. The apparatus was complete, and the experiments would be commenced in about six weeks.

Brighton.—In honour of the visit of the Prince of Wales the town was illuminated in the evening on a grand scale. Mr. Wright, the electrical engineer to the Corporation, arranged for search-lights to be fixed on the tower of St. Nicholas Church and on the top of the West Pier pavilion, and the electric light was also used to good account in the magnificent illuminations at the Royal Pavilion.

The Copper Trade.—Copper consumption was even greater in the second than in the first fortnight of February, but at the same time supplies were more plentiful. On January 31 G.M.B.'s were £43. 17s. 6d., on February 14 £44. 5s, and on February 29 £46. 10s. The price has since sagged a little, but promises to recover again.

City and South London Railway.—The returns for the week ended March 1 were £946, compared with £953 for the corresponding period of last year, being a decrease of £7. The total receipts for the half-year terminating as above were £8,860, compared with £8,941 in the same period of the preceding year, being a decrease of £81.

Ripon.—At the monthly meeting of the City Council it was stated that the Gas Committee had held a long discussion as to electric works for the city, and eventually the town clerk was instructed to obtain from the Dean and Chapter information as to the number of lights they will require if they adopt the electric light for the cathedral.

Chelmsford.—The past year has not been a very prosperous one for the gas company. At the annual meeting it was stated that the sale of gas had decreased by £150, but Mr. Duffield (the chairman) pointed out that the company had great competition to fight against—first, there was Messrs. Crompton and Co., and then there were also the oil lamps.

Stafford.—The Gas and Electricity Committee have reported that an agreement had been entered into with the County Council for the lighting of the County Council buildings, the Judges' House, and Eastgate House with electricity, the annual charge being £175, with the payment of 8d. per unit for all current supplied over 1,312 units per quarter, the number of lamps not to exceed 1,200 8-c.p., or their equivalent.

Fenton (Staffordshire).—On the new powers sought by the tramways company coming up for discussion in the Urban District Council, the clause relating to the supply of electrical energy met with objection. Mr. Hughes remarked that the company would be empowered to put electricity in competition with their gas at Fenton, where the Council were contemplating the spending of £6,000 or £7,000 more on their gasworks.

Nottingham.—In consequence of the development of their business, Messrs. Caddy and Co., Limited, furnace engineers, have found it desirable to reconstruct their company so as to admit the capital necessary for its increasing requirements. This has necessitated the formal winding-up of Caddy and Co., Limited, and in future the business will be carried on under the name of "Caddy and Co. (Nottingham), Limited."

Wakefield.—It is stated that the scheme for electric lighting, which has been standing in abeyance for some time, is shortly to be proceeded with. The committee who have the matter in hand have unanimously decided to recommend the City Council to proceed with the work. The Local Government Board have sanctioned the borrowing of the money required to defray the cost of the works, and tenders have been accepted for the necessary plant.

Larne Electric Light Works, Limited.—This Company was registered on February 24 by Milward and Co., 188, Fleet-street, E.C., with a capital of £4,000 in £1 shares. Object: to acquire the business of an electric lighting company, as hitherto carried on by J. E. H. Gordon and Co., Limited, at Larne, Ireland; to carry into effect an agreement with the Larne Town Commissioners, and to carry on the business of an electric light and power supply company in all its branches.

Derby.—The promoters of the Derby and Ashbourne Tramways Bill have officially notified the abandonment of the Bill for the present session. The promoters named in the Bill were Sir Henry Wilmot, V.C., C.B., Bart., the Hon. Frederick Strutt, Mr. Afred Charles Duncombe, Mr. Godfrey Frances Meynell, and Mr. John Shaw. The proposed tramway was intended to be worked upon the overhead trolley system of electric traction. The total cost of the tramway was estimated at £31,172.

Devonport.—At the meeting of the Borough Council Mr. Councillor Waycott moved: "That a special committee be appointed to consider the expediency of taking into consideration the subject of providing tramway or other vehicular accommodation between our fast-growing suburbs and the town." In view of the extension of Keyham Factory and the consequent increase of population, he said it was necessary that such an important matter should be considered. Mr. Harvey seconded, and the motion was carried.

Cork.—The Electric Tramways Company, Limited, have given notice of application to be made to the Lord-Lieutenant in Council under the Tramways (Ireland) Acts through the Grand Jury of the county of Cork at the next spring assizes, and to the Corporation of the city of Cork, for an order in Council to authorise the construction, working, and maintenance of tramways in the city and county of Cork, to be worked by horse power, electrical, or other mechanical power, with all necessary works connected therewith.

City and South London Railway Bill.—The second reading of the City and South London Railway Bill will be opposed by Mr. Lowles and Mr. Harry Foster, who intend to move the rejection of the Bill. Their ground of opposition is set forth in a motion which Mr. H. C. Richards proposes to move—viz.: "That it be an instruction to the Committee to make such provision in the Bill as will prevent the taking or removal of the church of St. Mary Woolnoth, or the use of the site thereof, or the churchyard, for the purposes of the company's undertaking, or from being in any way injuriously affected thereby."

Eccles (Lancs.).—The Town Council have after considerable discussion confirmed the following resolution, which was passed at a special meeting on the 24th ult.: "That, pending the application for borrowing powers, it is not advisable to appoint a deputation to the Board of Trade, and that it is not expedient to apply to that Board or the Local Government Board for an extension of time for carrying out the electric lighting scheme." The Town Hall and Electric Lighting Committee recommended that £1,073 of their proposed expenditure be taken out of the general district rate and £737 out of the borough rate. The estimate was adopted,

Digitized by Google

Aston (Birmingham).—Owing to the unsatisfactory nature of the electric light, both at the baths, the free library, and the Council Buildings, Mr. Vaudrey, C.E, has been consulted, and upon his recommendation the Highways and Buildings Committee have been authorised to put down a new steam-engine and dynamo, and to do other necessary work, at an estimated cost of £350, and the Urban District Council have now instructed the clerk to make an application to the Local Government Board for a loan for this sum.

Castleford.—The gas company have written to the Urban District Council in reply to a letter asking them to lower the price of gas and improve the quality, stating that they are unable to make any further reduction in price at present, as the consumption of gas had not increased. As to the quality, the gas had always been above the standard fixed by the Company's Act. The Council considered the reply very disappointing, and Councillor Townend said if the company did not try and meet them it would compel the incoming body to take steps by which there would be a considerable loss to the company. The matter has been referred to the Gas and Water Committee

Dover.—The electric light is proving very successful. The Dover Electricity Supply Company, Limited, commenced trading in April of last year, and already there is an equivalent to 4,600 8-c p lamps connected, and applications are steadily coming in. Their present system of supply includes 31 arc lamps for public street lighting, although the Town Council originally gave no guarantee that they would use the new illuminant. During 1895 the company were charging the maximum statutory price of 8d. per unit, but at the commencement of the present year the charge for current was reduced to 7d. for the first unit per lamp per month, and all current over this amount is at 5d

Preston.—The shareholders of the electric lighting company are well satisfied with the progress the concern is making In 1893 the income was £3,345 and the expenditure £4,345—a loss of £1,009. In 1894 the totals were respectively £4,778 and £3,783—a reduction in expenses of £571 and a profit of £995. Last year the income was £5 739, and the expenditure £3,339—a reduction in expenses on 1893 of £1,016 and a profit of £2,401. No dividend, however, is to be declared for the past year. The Corporation have decided to light several of the public thoroughfares and streets with electricity, so that altogether, it is believed, there are indications of progressive value in the Company's property.

Edinburgh.—The Lord Provost's Committee have recommended that no action be taken on the subject of a letter from Messrs. W. Dixon and Co, Glasgow, as to electric traction on the tramways This was expected to initiate a discussion in the Council. The recommendation was however, adopted by the Council, the Lord Provost remarking that up to the present they had not got anyone to tell them what electric traction would cost, unless that with the overhead wires, which the Corporation and the citizens had pronounced against over and over again. It was agreed to extend the public lighting by electricity along Morningside-road as far as Church-hill, and to light the West Port by the same means.

Derry.—At a meeting of the Corporation Lighting Committee Mr. Christie read a report, which, among other things, referred to the cost of running an electric arc lamp per year. Councillor Harper said he had gone very accurately into this question, and he found that in Newcastle-on-Tyne the Corporation paid £29 a year for each arc lamp; and the general average all over England was from £24 to £27, bringing up the average cost to £25 per lamp. Now, he would say that in the city of Derry it would cost a far larger sum, and in the future they had no prospect of it being less, because every day, every week, and every year it was increasing. To say that it cost only £20 a year to run an arc lamp was absurd.

Blackpool, St. Annes, and Lytham Tramways.—At the House of Commons Mr. Campion found that this Bill had complied with all the standing orders applicable to it at its present stage. The Bill authorises the Blackpool, St. Annes, and Lytham Tramways Company to revive the powers given them under their Act of 1893, and under this Act the company have to complete their authorised works within two years of the passing of the Act. They now seek to extend this period to 12 months after the passing of the present Bill. The promoters also desire power to lease and have running powers over the Blackpool Corporation tramways, to enter into working arrangements with the Corporation to acquire and work omnibuses, etc.

Wolverhampton.—At the general meeting of the gas company Councillor Jenks said he should like to hear if the company had been affected by the installation of the electric light. The Chairman replied that since the installation of the electric light the company had really had a larger number of customers. Alderman Owen said he believed there would be a large loss on the electric light undertaking in Wolverhampton. Alderman Annan said he did not think it would be a loss to the ratepayers if properly conducted, and he did not know any electric lighting scheme better managed than that in Wolverhampton. He did not make light of the electric light. The gas company must take care to keep well up to date with their works.

Catalogues.—We have received from Messrs. Dorman and Smith, of 94, Charing Cross-road, W.C., and Ordsal Works, Salford, a copy of their catalogue and price-list of electrical apparatus for 1896. It is a well turned-out book, and its contents covers the whole ground of electrical fittings. We have also to acknowledge from Messrs P. R. Jackson and Co., of Salford Rolling Mills, Manchester, a copy of their new catalogue of piston, pump, and packing rings. This firm has recently taken up the electrical engineering business. Their new shops are fitted with tools for the manufacture of dynamos, motors, switchboards, and electric light plant; and machinery for the general transmission of electric power in mills, ironworks, and mines.

Blackpool and Fleetwood Tramroads.—The Blackpool and Fleetwood Tramroads Bill has come before Mr. Campion, Examiner of Private Bills at the House of Commons, for investigation of standing order proofs. The Bill proposes to enable its promoters to construct tramways and a tramroad between Blackpool and Fleetwood. Its consideration has been postponed on various occasions, and Mr. Campion having found that the standing orders had not been complied with, as the promoters had failed to obtain the consent of all the local authorities having jurisdiction over the roads on the line of the proposed tramroad, Mr. Campion will report the non-compliance to the House of Commons in due course. This does not necessarily mean that the Bill has been dropped.

Newmarket.—At the meeting of the Urban Council a letter was read from the Board of Trade asking for the observations of the Council on the request of the promoters of the Newmarket Electric Lighting Company that the consent of the Council should be dispensed with. Another letter was also received from the Board enclosing a memorial forwarded by the promoters, signed by a number of leading residents in favour of the scheme. The Chairman said the surveyor had informed him that he would, if required, prepare a report at once on the question of supplying the district with the electric light. He suggested that the Board of Trade be informed that the surveyor was in a position to make a special report on the subject for consideration of the Council at their next meeting, after which they would reply more fully to the Board's letter. This was agreed to.

Stapleton.—The Clerk to the District Council submitted at the Council meeting a letter from the Board of Trade with reference to the Council's opposition to the powers sought by the Great Western Electric Light and Power Company, stating that the company had withdrawn their application for such powers; and he also stated that it was now understood that the Bristol Tramways Company would, by the end of the summer, apply for powers to extend their system of electric tramways to Fishponds; that the general fare would be 2d., and for workpeople 1d. Mr. Harris proposed and Mr. Tarlton seconded, "That the company be asked to fix the Fishponds terminus at the junction of Downend and Staplehill roads" This was carried. It was also resolved, upon the motion of Mr. Monks, seconded by Mr. Cool, that the company should be asked to put down wood paving inside the rails of the line.

Barcelona Tramways.—The directors' report states that no distribution of dividend is yet possible. In pursuance of the policy announced at the previous general meeting, the company has presented to the authorities a petition for the power to substitute electric for animal traction, accompanied by all needful plans, specifications, etc. The formalities to be gone through in Spain in matters of this nature are protracted and tedious, but there is no reason to fear that the application will not be granted. In view of the early adoption of the new mode, the directors are about to ask the shareholders to create additional capital to the extent, in all, of £150,000, divided into £50,000 in ordinary and £100,000 in 5 per cent. cumulative preference shares, which they estimate will be sufficient to cover the necessary outlay for the electrical installation and equipment, and the payment for the purchase of additional land.

Portsea.—On the spot where the main prison building used to stand, Messrs. Martin, Wells, and Co., of Aldershot (who are represented at Portsmouth by Mr. Moss), are erecting a new dockyard electric shop, which is to measure 348ft. in length, 42ft. in width, and about 28ft. in height. It will be built of brick, with stone dressings, and a slate roof. Inside, the latter will be supported by iron and wooden rafters. Plenty of large iron-sash windows are being provided. The floor is to be paved with wooden blocks, and a gallery will run around the building. On the ground floor rooms are to be provided for the electrician and his leading men, and the plans further provide for a drawing office, a plating-room, and extensive stores. Steps are being taken to fit the shop with the latest type of electrical machinery, etc. Additions and alterations are in progress whereby one portion of the old prison shoemakers' shop will be converted into a boiler-house, with engine, dynamo, and testing rooms adjoining.

Camberwell.—At a meeting of the Vestry Mr. Phillips, on behalf of the Special Electric Lighting Committee, presented an elaborate report with reference to the projected application of the County of London and Brush Provincial Electric Lighting Company for a provisional order to supply electric lighting in the parish, and setting forth the terms upon which the Vestry would consent to the order, among these being a provision requiring the company to sell their undertaking at any time after the expiration of 21 years. He now moved certain emendations upon the report already adopted, stating that the Vestry had applied to the Board of Trade for certain powers, which were greater than any powers granted to other parishes except those that had asked for the electric lighting to be in their own hands. The Board of Trade had granted the powers, but there were a few trumpery proposals that they declined to accede to. He asked the Vestry to accept the position laid down by the Board of Trade, because if they did not do so they would be disallowed the advantages already granted. The recommendations were carried.

Belper.—At a meeting of the Rural District Council Mr. Teale asked if they were to have any information as to the powers of persons to carry wires overhead for electric lighting purposes. The Clerk stated that a person could carry a wire over a public

Digitized by Google

road without permission of the authority, providing it was over 30ft. from the surface of the road. Mr. Smedley had his name to the following notice of motion: "That in the opinion of this Council the time has arrived when we ought to have the necessary powers for lighting our streets with the electric light, and in order to do this the clerk be instructed to apply to the Board of Trade for a license authorising this Council to supply electricity under the Electric Lighting Act, 1882, for any public or private purposes within the area of the Belper Urban District Council for the next seven years, and that the resolution be considered at a special meeting of the Council to be specially convened for that purpose." The Clerk stated that a full month's notice would have to be given to comply with the Act, whereupon Mr Smedley consented to the motion being put down for consideration at the April meeting of the Council.

Fife Police and Telephones.—A deputation from Fife County Council has waited upon the Secretary for Scotland in Edinburgh to solicit his lordship's aid in obtaining from the Post Office telephone facilities for the police at more moderate rates than the ordinary charges. At present, it was explained, the cost of the messages which it was necessary to send per annum would, at the usual rates, amount to about £500. Sir Ralph Anstruther submitted that the County Council thought that if it were the desire of the Crown authorities that telephonic facilities should be increased, the Crown authorities should give them assistance in getting these facilities at a cheap rate. Formerly, the County Council paid a lump sum per annum to the Telephone Company, and they wished to follow a similar course with the Post Office, but the postal authorities said they had no power to make any such arrangement. Lord Balfour, in reply, said the request was one which ought not to have been made to the Secretary for Scotland, but to the Post Office Department and the Treasury, but he agreed with all they said of the importance of having rapid telephonic communication for police purposes.

Messrs. Crompton and Co.'s Proposed New Works.—The *Essex Chronicle* says: "It is said—and said, we believe, with truth—that the negotiations between Messrs. Crompton and Co., Limited and the trustees of the Johns estate, with reference to the acquirement of a site for the proposed new works near the railway line by the Writtle-road Bridge, are not progressing as might have been wished. This is distinctly bad news, for it will be a most unfortunate thing for Chelmsford if Messrs. Crompton should seek a site for the works in some other town. We most earnestly hope, alike for the sake of Chelmsford, the electric lighting firm, and the development of the Waterhouse Farm estate, that the hitch which exists will be speedily got over. On both sides of the bargain which has been contemplated we would respectfully urge moderation, so that terms may be agreed upon if possible. From the point of view of the future progress and prosperity of Chelmsford, this matter is of the utmost importance. In fact, it would pay the town to present Messrs. Crompton with a site rather than let them go elsewhere with these works, which would create a large additional wage and salaries fund for expenditure here, and improve the borough in every way."

Dublin.—The members of the Corporation have met in committee of the whole house to consider the rival electric tramway schemes. The proceedings were private, but it is stated that a resolution was adopted to the following effect: "That the United Company be allowed the use of electricity on their existing 17 miles at a rental of £300 a mile for each mile in which there was an installation; that they should not be given a monopoly of tramway rights in the city, and that the rental be subject to revision every seven years." A meeting in opposition to the electric tramway scheme has been held. At the beginning of the proceedings there was a great deal of uproar and confusion, in the course of which some rotten eggs were thrown from one end of the room to the other. The police were called in and they expelled several people. Business was then proceeded with, but the opposition being too numerous to be expelled *en masse*, the interruptions continued unabated to the end. On the report of the committee with reference to the proposals of the Dublin United Tramways Company and the Dublin Southern Districts Tramway being discussed in the Town Council, it was decided to postpone a decision on the matter for six months.

Foleshill (Coventry).—At a meeting of the Parish Council Mr. Ivens and Dr. Orton reported on their interview with Mr. Willmot, county surveyor, with respect to the dangerous condition of several of the tramway poles at New-inn Bridge and other places. Mr. Ivens said Mr. Willmot did not think the poles were so bad, but that it would be better to have them altered. He thought, however, that the greatest improvement would be to take away the loop lines at New-inn Bridge and Oak's-yard and he (the speaker) agreed. Dr. Orton alluded to the dangerous position of the poles at the places mentioned, and agreed that the taking away of the loop lines would be the best improvement. New-inn Bridge was positively dangerous. He moved that as Mr. Willmot and the deputation were of opinion that the poles were dangerous, the Council agreed it was advisable that the loop lines at New-inn Bridge and Oak's-yard should either be removed or the position of the poles altered. The motion was seconded and carried. An amendment that the Council proceed to the next business on the ground that the Local Government Board inspector's report stated that the trams were not to pass each other at the places mentioned, proposed by Mr. Carpenter, was not seconded.

Peterborough.—The following report of the Electric Lighting Committee was read at the Town Council meeting: "Mr. Batten proposed 'that the engineer prepare and produce on Friday, February 28, a statement giving detailed estimates of the annual expenditure in connection with the proposed electric lighting of the prescribed area in the borough, showing particulars of the working expenses, depreciation of plant and interest upon loan of £20,000 and proportionate repayment of the same within 25 years; also an estimate of the number of electric lamps at 6d. per unit required to provide for such annual outlay; and a separate account of the cost per annum of the street-lighting contemplated in the scheme, and of the account now paid for the gas lighting of the same streets.' This was seconded by Mr. Herbert. For the motion 10, contrary 8; the motion was therefore carried." Mr. J. Hunting challenged the confirmation of the minute, remarking that the discussion on Friday was a little heated. It was an utter impossibility for the details to be prepared by the time named, and he moved that the time be extended for three weeks. Mr. Batten said he did not object. Alderman G. Hunting seconded. Mr. Batten asked if the town clerk had heard when the commissioner was likely to come down. The Town Clerk said he had not. The amendment was agreed to.

Ealing.—At the meeting of the District Council the Electric Lighting Committee reported that they had considered draft plans for the provision of increased accommodation at the electrical works, and they recommended, in view of the many applications for electric light and the necessity of laying down extra machinery in the near future, that the plans should be put in hand and the necessary drawings prepared. The surveyor reported that the total of applications for private lamps had now reached 6,158, and of these 5,627 had been connected. Mr. Baker Hays asked how far they were from clearing up the initial expenses. The Surveyor: All but one of the original accounts have been paid. Mr. Baker Hays remarked that the incandescent street lamps seemed in every way admirable; they gave a much better light than the gas lamps. The Surveyor: Yes, the light is better and each lamp is a customer. Mr. Box: Have Messrs. Bramwell and Harris fufilled their promise to considerably reduce the original accounts? The Surveyor: Yes, in one instance an account was reduced by £1,100. The Chairman, reverting to the recommendation of the committee, remarked that the extra work was only what was anticipated, though it would require to be done sooner than was expected. The Council ought to feel gratified that that was the case. The recommendation of the committee was adopted.

Waterloo (Liverpool).—At a meeting of the Parish Council Councillor Taylor expressed the opinion that it would be advisable that members should have a printed copy of the proposed scheme of the electric tramways through the district and then they would be in a position to know what the promoters were asking for. The Clerk said the provisional order was printed. Councillor Williamson said he had not previously heard anything being said about the overhead or underground wires. Councillor Taylor said his impression was that the Council were going to support the scheme, their strong reason for doing this being that they required such a scheme, and were inclined to support anyone who promoted it. The Clerk said the overhead wires had been mentioned before, because at the last meeting a letter on the subject was read. Councillor Williamson said it had clearly been an oversight on his part, but it was immaterial to him whether the wires were overhead or underground. Councillor Johnson said he had not the slightest objection to the overhead wires. He had seen them in Dublin, and they were neither dangerous nor an eyesore there. The Chairman pointed out that tall loads of waste were brought down Oldham-road and these might interfere with the wires. Councillor Johnson said the highest load which ever passed on the road would not touch the wire. It was decided to hold a special meeting to consider the subject.

Morecambe.—An extraordinary general meeting of shareholders of the Morecambe Electric Light and Power Company has been held for the purpose of passing a resolution for voluntarily winding up the company. The meeting was called in consequence of a petition in bankruptcy lodged by the Bank of Liverpool, the company's bankers, who intimated their willingness to withdraw this if the company decided upon voluntary liquidation. Mr. W. B. Hodgson, chairman of the company, presided, and there was a fair attendance of shareholders. After several questions had been replied to, the resolution was adopted, Mr. C. R. Compston, Lancaster, being appointed liquidator. The secretary subsequently gave an account of the financial position of the company. The non-success is understood to be mainly attributable to inadequacy of capital, to the result of proceedings at the instance of residents in the vicinity of the generating station for nuisance caused by the alleged emission of noxious vapour from the motive power employed, and other unforeseen difficulties they had met with. The District Council have received authority for a meeting of ratepayers to carry out a provisional agreement for taking over the undertaking and mains of the company. The total cost of the installation for public and private lighting is estimated at £16 000, inclusive of £3,950 to be paid for the present mains. The latter are calculated to supply 122,000 units, in addition to the public lighting of the town and promenade.

Kingstown (Ireland).—In the Kingstown Police Court on Friday, before Mr. Byrne, Q.C., the directors of the Dublin Southern Districts Tramway Company were summoned by the Dalkey Township Commissioners for having failed to carry out the provisions of the order obtained by them for the construction of the electric tramway line by omitting to restore portions of the roads to a proper state of repair. Mr. M'Laughlin (Messrs. M'Laughlin and Ireland, solicitors) appeared for the complainants, Mr. Walsh, C.E., township surveyor, and Mr. O'Neill, town clerk, being in attendance. The defendants were represented by Mr. Dudley (Messrs. O'Connor and Dudley, solicitors), Mr. J. Clifton Robinson, C.E., managing director, and Mr. S. J. Fraser, the company's engineer, being also present. Mr. Dudley raised the preliminary objection

Digitized by Google

that the magistrate had no jurisdiction to hear the case, contending that such summonses could only be heard before justices in England and Scotland under the provisions of the Tramways Act of 1870 Mr. M'Laughlin argued that the Act having been applied to Ireland afforded a summary remedy before a magistrate. Mr. Dudley said the order under which the company were making their tramway provided the remedy for cases of the kind. An application should be made to the Board of Trade, and that body could hold an enquiry. The present proceedings were apparently taken with the object of discrediting the company Mr. Byrne dimissed the summons, holding that he had no jurisdiction to try the case. There appeared to be a *casus omissus* in the Act with reference to Ireland, and the proper body to settle the matter was the Board of Trade. Mr. Dudley applied for costs His Worship said he would allow 10s. costs.

Bucklow (Cheshire)—Trouble has arisen between the Rural Council and the Altrincham Electric Company It appears that at a meeting of the Council of December 14, Mr Fawcus of the Altrincham Electric Supply Company, Limited, agreed to do certain things subject to the Council giving their consent to the company's application to the Board of Trade for a provisional order extending the area of supply by including Timperley and another road in Hale. One of the conditions under which the Council gave their consent was that the company would repay to the Council the cost of the repairs of the road after disturbance both in the old and new area of supply, in accordance with a scale approved by the Council. The Clerk now stated that he wrote to Mr. Fawcus, asking whether he declined to comply with the undertaking which he gave on that occasion, as if not it was not the intention of the Council to approach the Board of Trade with reference to the terms under which their consent was given. Mr Fawcus had replied to the effect that he could not consent to the extended operations which the Council now thought fit to give to the undertaking, as he contended that such undertaking referred to the new area and not to the old at all. He would be pleased if the correspondence which had passed between the Council and himself on this matter were brought before the Board of Trade should the Council think it desirable to do so. The Council unanimously decided that the Board of Trade should be acquainted with the full conditions under which their consent was given to the company's application, and it should be explained to them that if those conditions had not been agreed to at the time, their consent would have been withheld.

Kingston-on-Thames.—The business of the municipal electric lighting station commenced in October, 1893, and capital to the amount of £22,770, repayable in 25 years, has been expended. From the period of commencing until December 31, 1894, the total expenditure, excluding loan repayment, and interest, was £2,540. 19s 2d., and the total revenue £1,985. 19s. 7d. The amount receivable for the sale of current for the first quarter of 1895 was more than double the receipts for the corresponding quarter of 1894; and in May, 1895, current equivalent to 4,150 8-c.p. lamps was being supplied (including the illumination of the town hall, Corporation offices, and free library) So far as can be ascertained at present, the revenue for 1895 will clear working expenses but not any portion of the repayment of capital and interest. Mr. J. E Edgcome, A.M.I.M.E., A.M.I.E.E., the borough electrical engineer, states that as a large number of the present consumers came upon the mains at the end of the year, their accounts for 1895 represent only a few weeks' consumption and they would, of course, largely increase the revenue for the current year, exclusive of the customers likely to come on. The street arc lighting is charged at the extremely low rate of 2½d per unit instead of, as is frequently the case, street-lighting being charged at the same rate per unit as that supplied to private consumers. This, of course, made a great difference in the revenue returns for the works, although there was no difference to the ratepayers, as what they gained upon the increased revenue on the works they lost in extra payment for street-lighting. The 36 arc lamps have displaced 114 gas lamps, and the amount of light in the streets is five or six times greater than formerly. The charge to private consumers is 6d. per unit.

Ayr.—A special meeting of the Town Council has been held for the purpose of considering the minutes of the Lighting Committee. Provost Willock, who presided, explained that the object of the meeting was to get power to proceed with certain works for finishing up little matters in connection with the electric light. They had been obliged to call the meeting because the Lighting Committee had not powers. Mr. Grant stated that before proceeding to discuss the minutes he had a motion to make. Provost Willock ruled Mr. Grant out of order. Mr. Grant said it was a pity he was out of order, for there had been nothing but blunder after blunder. His motion was to appoint an electrical engineer to supervise the works altogether. It was agreed to charge £3. 10s. for the light supplied at the hospital ball, and on a division it was agreed that £10 should be the charge for the electric light at the art exhibition in the Carnegie Library. Mr. Hammond, electrical engineer, explained to the committee that the testing of the transformers had disclosed that they were one-third below the specified dimensions, and the meeting requested him to give a written report on them with the view to intimating a claim against Messrs. Swinburne for the whole extra expenditure which their failure entailed. Mr. Hammond recommended that seven transformers should be purchased as against those which Messrs. Swinburne had failed to supply, and in view of the urgency of the matter the committee approved. It was agreed to discuss this matter in private. Two offers for seven new transformers have been received—one by Siemens and Co. at £476, to be delivered in 11 weeks, and the other offer by Messrs. Fowler at £630, to be delivered in six weeks. It was agreed to delay the matter until the engineer was further communicated with.

Leeds.—On the minutes of the Highway Committee coming on in the Town Council Mr. Hannam proposed: "That the resolution passed by the Council on October 15, adopting the report of the Highways Committee upon tramway traction, be rescinded so far as regards the recommendation for an electric conduit system in the centre of the city, and that the Council approve the resolution of the Highways Committee to adopt the overhead electric system for the line from Roundhay to Kirkstall throughout, centre poles being used where practicable." After much consideration the committee came to the conclusion that the wisest course for them to adopt would be to visit Bristol and inspect the most modern overhead tramway electric system at work in that city; and having done so, they were almost unanimous in the opinion that they should be perfectly safe in asking the Council to adopt overhead wires along Boar-lane. Mr. J. F. Carter seconded. Mr. Mark Scott thought the committee should furnish an estimate of the shallow-conduit system. While not opposing electric haulage, he felt that the traffic in Leeds streets would be interfered with by the proposed system. Mr. Laycock, quoting from a circular, said the cost per mile at Bristol was £17,150, but Mr. Hannam subsequently said the capital cost of the four miles at Bristol was £50 000 The cost of the working could not be obtained. Alderman Firth expressed astonishment at the statement that the cost per mile at Bristol was 17,000 The compiler of that circular, he maintained, had left out of account the fact that practically a new permanent way had been put down for six miles, and that the £50,000 also included engines, cars, and all the electrical plant—in fact, the cost of the whole of the requirements of the Board of Trade. After further debate the resolution was agreed to.

Fareham.—A special meeting of the Urban Council has been held to consider further replies on the matter of the purchase of the electric light. The clerk read a letter from the Local Government Board to the effect that they were not prepared to reconsider their decision with regard to the sum of £200 and £120 as additional loans for the purchase of the electric lighting works. The clerk also read a letter from the Board of Trade stating that the Board would, on receiving an assurance in the form of a resolution of the Council that the wires referred to in Section 82 of the order should be placed underground within three months from the date of the transfer, be prepared at once to consent to the transfer. On the proposal of Mr. Abraham, seconded by Mr. Etherington a resolution was passed that the Council undertook to place the wires underground within the required three months. Mr Manville, with whom the clerk had had an interview at Portsmouth on the 15th ult., wrote that he should be prepared to report upon the plant, to prepare specifications, and to superintend the laying of the wires at the usual fee of 5 per cent on the contract, with a minimum fee of 75 guineas. It was decided to accept these terms, and to ask Mr. Manville to meet the Council in committee at an early date. Ten tenders for the proposed loan of £6,681 for the purchase of the works were received, and that from the Capital and Counties Bank, at 3 per cent. interest, with expenses of only £8 15s. for stamp duty, was unanimously accepted. The Council considered the negotiations which had been in progress between the agents of the opposing parties as to the final settlement. It was decided that the payment should be at 3½ per cent. interest from November 21, or 5 per cent. upon the debentures, and 3½ per cent. upon the shares if from March 17, and that the payment of the costs should be by instalments Eventually it was agreed that both parties should recommend counsel to select a date midway between the two named, and that the costs should be paid in four instalments.

Bristol.—The Sanitary Committee and the Electrical Committee having been appointed a committee to consider and report upon the question of introducing the overhead trolley system of electric traction into the city, they have met and have finally resolved to obtain the opinion of an expert as to the best system of electric traction, and to ascertain under what conditions electric traction is permitted in other towns, and what are the terms under which the tramway companies have the use of the streets. The Electrical Committee have had before them an application from the Stoke's-croft and North-street Ratepayers' Association for public electric lighting in those thoroughfares. The committee agreed to instruct the secretary (Mr. Prosser) to reply that the question of extensions generally was being considered, and that they hoped in the course of, say, three months to be able to report to the Town Council on the matter. The printed annual statement of accounts was before the committee, and was regarded with much satisfaction. The accounts are for the year ended Decembr 31, 1895, and show a gross profit of £4,019. 19s. 10d., as compared with £456. 7s. 11d. in 1894. The profitable demand for the light still continues. The total of borrowed money is £100,000 and of this £97,794. 11s. 10d. had been expended at the end of the year. The sum of £4,577. 11s. 9d. was received from the general district rate, or about a penny in the pound on the ratable value. In respect of the existing loans, £7,240 has been repaid, leaving £92 760 still owing. A balance of £1,786. 11s. 11d. is carried forward from net revenue to the current accounts. There were 408 301 Board of Trade units of electricity sold during the year, of which 251 708 were consumed by private consumers and 156,893 by the 99 public lamps which are supplied by the current. The cost of street-lighting for the 12 months was £3,447. 3s. 10d., or, roughly speaking, £34 per annum per lamp. This cost includes cleaning, replenishing, etc. It is not easy to compare the cost of these lamps with gas lamps, but, of course, the sum is considerably higher than for gas lamps. Against that fact, however, has to be set the greater illuminating power. At the request of the St.

Digitized by Google

George's Urban District Council. the tramway company have agreed to a reduction of fares The Council have agreed to a further extension along the parish boundary.

Hampstead.—At a meeting of the Vestry the Lighting Committee reported that they had carefully and fully considered the question of what additional boilers would have to be laid down at the central electric lighting station for the winter of 1896-97; that they had considered the various types of boilers most suitable to the proposed new additions, and had received tenders and specifications from four firms; that, after careful consideration the committee were of opinion that the type of boiler manufactured by Messrs. J. Brown and Co. was the one most adapted to the space at the Vestry's command, and to meet their requirements; and therefore they recommended that two of Messrs. Ellis and Eaves's fire-tube marine boilers be ordered from Messrs. J. Brown and Co, Sheffield, at the price of £3,500, subject to that firm entering into such a contract with the Vestry as may be approved by the committee. Mr. Thwaites, chairman of the committee, in moving the adoption of the recommendation, said that it had become necessary to enlarge the station owing to the great increase in the number of customers. He also explained that it was necessary to decide upon the type of boiler before they could prepare plans for the enlargement of the existing buildings The recommendation was adopted. The same committee recommended that Messrs. Siemens Bros. and Co., Limited, be informed that the Vestry are not satisfied with the working of the arc lamps in Finchley-road during their two months' trial; that they are going fully into the matter, and will be in a position to communicate with them further on the subject shortly. This was adopted. Mr. Newton asked what was the cause of the electric light suddenly failing at the vestry hall on the previous Friday evening. The electrical engineer said that the failure was caused by the blowing out of a fuse. He had made arrangements for a periodical examination of the installation in the building to be made in order that nothing of the kind might occur again. It was resolved to lay a new underground telephone wire from the vestry hall to the stoneyard at a cost of £35.

Croydon.—The Electric Lighting Sub-Committee reported to the borough County Council that they had accepted the tender of Mr. S. Page for the electric lighting station buildings, offices, etc. They had received the following report from Prof. Kennedy: "The details as to clauses of contract and of specifications are now settled with the British Thomson-Houston, as also are final amounts of prices. The original tender of the British Thomson-Houston was drawn very fine indeed, and for the future good working of the station it has been necessary for me to add several matters. I have also been very anxious to avoid the chance of your having to pull up the streets again unnecessarily soon, as would be the case if the mains now put in were only just equivalent to the first instalment of lamps. All these matters are taken account of in the specifications and prices. I think that it would be as well that the condensing plant and pipes should be omitted at present. You will by this means save something like £1,100 out of the British Thomson-Houston tender, and the efficiency of the station will not be reduced. The actual cost of working will, of course, be somewhat greater to the contractors, as they will no doubt use more coal. But this section of the plant can be added whenever you think proper later on." The chairman of the committee had prepared a revised plan showing the proposed method of public lighting by arc lamps in the compulsory area, which the sub committee approved and recommended for adoption. The estimated extra cost of these lights over the price now paid for gas lamps in the above area is about £350 per annum. The sub-committee had considered a memorial signed by 59 residents in High-street, Friends'-road, and Park-lane, requesting that the proposed installation might be extended from Mint-walk, along High-street, up Friends'-road, returning along Park-lane to Katharine-street; but they did not recommend that any extension of the area be undertaken at the present time. Councillor Moss moved the adoption of the report. Alderman Miller seconded, and said that the mains now being laid for the central area were sufficiently large to extend to Addiscombe, Park-lane, South Croydon, and thereabouts, with, of course, additional sub-stations. They would also, doubtless, arrange to take the light to Norwood. When a demand came they would be prepared with a supply. With regard to the question discussed at the last meeting of lighting the compulsory area by means of arc lamps he had prepared a plan showing the position of 38 arc lamps, which would displace 62 burners now in existence. He was not prepared to give the Council the exact cost, inasmuch as since the last meeting Prof. Kennedy and the contractors had suggested a smaller lamp of 1,500 c.p instead of 2,000 c.p. They did not think that streets like North-end and High-street were sufficiently wide to require such powerful lamps as were originally suggested. The price of the smaller lamps worked out at £16 per lamp. The report was adopted.

Maidstone.—The question of disposing of the provisional order came before the Urban District Council last week. His Worship the Mayor presided. Alderman Charles Ellis moved the adoption of the committee's recommendations that the Council dispose of the provisional order to Mr. King for £500, the cost of obtaining the order, under certain conditions. He said the electric lighting order was obtained in 1892, and between then and now a considerable amount of discussion had taken place upon the subject. Mr. Hawtayne's scheme was rejected in 1893 by 17 votes to 3 and a resolution was then passed declaring that in the opinion of the Council it would be expedient to obtain a company or private firm to carry the out order. Accordingly, negotiations were opened with Messrs. Bourne and Grant, of the Electric Construction Company, but nothing was arranged, and at the end of 1894 the committee were reinstructed, being told to find some mode of disposing of the order. Acting on their fresh instructions, the committee made another effort, and at last got an offer from Mr. King, who said he was prepared to form a company to carry out the undertaking. Their report was presented to the Council on January 13 last. The terms upon which the order was to be transferred included the payment of a sum of £500 The Council were not to be bound to take any supply for public lighting, but if they did take electricity for that purpose they were to have it at 20 per cent. less than the cost to private consumers. The Corporation officers were to have the right of entrance to the company's works to see how things were going on; and there was a clause in the agreement for the regulation of the price to be charged for electricity supplied. If the company earned more than 10 per cent., the public must benefit in the shape of a reduced price On top of all this the Council could buy the undertaking, on giving six months' notice, at the end of 21 years, or after every subsequent five years at a fair market value as a going concern, with 10 per cent. added for compulsory purchase, excluding any consideration as to future profits. Another point to be considered was that the Council had had no application from the ratepayers, to his knowledge, for electric light. According to the unanimous voice of the speakers at the public meeting, electricity was to be the light of the future, and certain towns in which it had been installed were referred to—Brighton, for instance. But there was no comparison between that place and a quiet country town like Maidstone. Mr. Monckton (the town clerk) read a letter from Mr. King, stating that he was willing to increase his offer from £500 to £750 if the Council would carry out the heads of the agreement. Mr. Morling said they had not had the advice of a practical electrical engineer, and before they disposed of the order they ought to take counsel with some eminent man like Mr. Preece. It would be money well spent. Mr. Cox moved an amendment, "That in view of the resolution passed by the public meeting, and the further offer of Mr. King, the report be referred back to the committee for further consideration," and this was carried by 12 votes to 8.

Birmingham—The expenditure for the year 1896-7 on electric lighting, pumping machinery, storage tanks, and steam-generating plant at new meat market is estimated by the Finance Committee at £12,000. The directors of the Birmingham Electric Supply Company report that the amount of net profit, including the balance of £1.001. 11s. 9d. brought forward from last year, is £6,570. 11s. 8d. Out of this the directors recommend the payment of a dividend of 4 per cent., absorbing £3 629 9s. 9d., placing £1,920. 9s. 11d. to the credit of the depreciation reserve fund, and a further sum of £250 to the general reserve fund, carrying forward the balance of £770. 12s. to next year's account. On making the above appropriation, the total reserves and undivided profits will amount to £9,463 18s. 6d. There has been a steady increase in the company's business during the past year; the total number of 16-c.p. lamps, or their equivalent, on order December 31, 1894, was 12 138, and on the same date in 1895 the number was 18,199. The additions since the close of the financial year have brought the number up to 19,401. The expenditure on capital account during the past year has been £50 537. 2s. 1d. Considerable additions have been made to the plant and machinery at the Dale End works. Included in the capital expenditure are the buildings and partial equipment of the company's new stations at Edgbaston and Newhall-street, as also the underground mains that have been laid through a considerable portion of the company's new parliamentary areas. The directors also report that the two new stations are now in full working order. In the Edgbaston district the supply has been only available since October last, and the orders already received are encouraging. In the jewellers' district the demand for current, both for lighting and power purposes, considering the few weeks the supply has been on the mains, is most satisfactory. The reduced scale of prices adopted by the Board last year has had the effect of increasing the number of consumers and augmenting the company's business, and the slight falling off in the revenue caused by these reductions has now been overtaken, and justifies the policy adopted. The increase during the year in the use of motors has been considerable, and will no doubt in time became an important addition to the company's resources. To cope with the output in the future, additional plant has been ordered for the equipment of the Dale End station, and generating plant is in hand for the Newhall street depôt. As authorised by the shareholders at the last annual meeting, the registered capital of the company had been increased from £100,000 to £200,000, and in October last 10,000 shares were issued at a premium of 5s. per share, and, in accordance with the resolution passed at a special meeting of the shareholders, the £2 500 received for the premium has been applied as follows: to writing off preliminary expenses, £1 685. 2s. 4d.; to writing off expenses incurred in the recent registration and issue of new capital, £154. 10s.: and the balance towards the reduction of the charge on account of the company's provisional order, £660 7s 8d.—£2,500.

Lancaster.—At the meeting of the Town Council the Electricity Committee reported that they had instructed Messrs. Sharpe and Co., of Westminster, to oppose before the Privy Council the renewal of the patent of the Westinghouse Company on behalf of the Corporation The committee had appointed Mr. C M. Johnston electrician at the electricity works, at a salary of £100 per annum, he to perform such duties as the committee may from time to time determine, and to act under the instructions of the borough surveyor. On the motion for the confirmation of the minutes of the Electricity Committee, Mr. Alderman Smith drew attention to the very signal proof of the sound advice given by one or two of

Digitized by Google

them last year, when they opposed the reduction in the price of current from 7d. to 5d. per unit Mr. Storey, himself, and the officials were all agreed that in offering current at 5d. they would certainly incur loss. The argument on the other side was that the reduced price would mean greater consumption, and it would be better than allowing the plant to be unemployed. Their worst fears had been realised in the balance-sheet, which showed that the electric light during the past year had been a loss to the town of £500 practically a penny in the pound on the rates. He did not think they had any right to supply electricity at a penny per unit less than it cost. Electric light was a luxury, and he did not suppose 5 per cent. of the ratepayers were consumers. Therefore they were making a present to a few at the expense of the many. It was true there had been some increase in the current consumed as the result of the reduction, but it was a very small one, the figures showing 58,000 units against 46,000 last year. He did not wish to move an amendment, but he thought it would be wise even now to revert to 6d. per unit and reduce the vexatious charge upon the meters. If they increased the price to 6d. they would have an increase in revenue of £240 or £250, which was pretty nearly equal to the deficit estimated for the coming year, which amounted to £280. Mr. Alderman Bell said Mr. Smith had hardly put the matter right. The recommendation of the committee was that the price be reduced from 7d. to 6d., and that they should get a current indicator, so that people who consumed light during a long period should pay less than was paid for a shorter period. If they had adopted that recommendation their loss would have been considerably more than £500, because people were giving up the light rather than pay the price, so that instead of an increase from 46,000 to 58,000 they would have had to report a decrease. He supported the action taken by the majority of the Council at that time. Mr. Hall said it was the intention of the committee to go thoroughly into the question at the end of the year. He voted for the reduction in price, but they were then told that electricity could be produced at a certain price, and they had found that information was not exactly correct. During the past year the cost of production had been reduced from 6d. per unit to a decimal over 3d., but. of course, that did not include interest and redemption. The increase in custom had been 27 per cent., which was not quite equal to the reduction made in the price. The minutes were confirmed.

PROVISIONAL PATENTS, 1896.

FEBRUARY 25.

4174. Improvements in the method of fixing caps to incandescent electric lamps, and in joining the leading-in wires of such lamps to contact plates. J. A. Sinclair, 55, Rowan-road, Hammersmith, London.

4175. (The sparkless) switch. J A. Fisher, Berea House, Gillott-road, Edgbaston, Birmingham.

4179. Improvements in electric road vehicles actuated by electricity. Thomas Machin, 36, Temple-street, Birmingham.

4207. Improvements in instruments for measuring electric currents. William Thomson (Baron Kelvin). 154, St. Vincent street, Glasgow.

4234. Improvements in electric lamps for vehicles. John Zimmerman, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

4237. Improvements in continuous-current electric motors and method of regulating the same. James Devonshire. 70, Chancery-lane, London. (Elihu Thomson, United States.) (Complete specification)

4238. Improvements in windings for armatures of dynamo-electric machines and motors. James Devonshire, 70, Chancery-lane, London. (Walter H. Knight (United States) (Complete specification.)

4261. A new or improved electrical lamp. Herbert John Dowsing and Henry Sheehy Keating, 28, Southampton-buildings, Chancery-lane, London.

FEBRUARY 26.

4345. Improvements in the production of gas by means of electricity. John Henrique Dunn and Robert Graeme Elphinstone Dalrymple, 47, Lincoln's inn-fields, London.

FEBRUARY 27.

4369. Improvements in wooden casings or mouldings for electric conduit wires and cables. Charles John Wightman and Arthur Hudson, 2, Market-street, Bradford.

4371. Improvements in the construction of standards of electrical resistance. Andrew Duncan Hughson, 51, Wightman road, Harringay, London.

4393. Improvements in filaments for electric incandescent lamps. Godfrey Bamberg, 33, Barcombe-avenue, Streatham-hill, London.

4404. Improvements in electric switches. Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster.

4406. Improvements in and connected with electrical storage batteries. Edwin Augustus McLachlan, 11, Furnival-street, Holborn, London.

4427. Improvements in the construction of armatures for alternators and such like machines. Horace Field Parshall and the British Thomson-Houston, Limited, 70, Chancery-lane, London. (Complete specification.)

4432. Improvements in electrical resistances. William James Davy, 40, Chancery-lane, London.

4434. Improvements in or connected with moulds for use in the manufacture of secondary battery plates or supports. Frank King, 47, Lincoln's-inn-fields, London.

FEBRUARY 28.

4490. A compensated hot-strip ammeter for the measurement of electric current. Herbert Brandon White, 6, Cholmeley-villas Highgate, London.

FEBRUARY 29

4617. Improvements relating to electric railways. Carl Coerper, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

NOTES.

The Cinematograph.—Mr. Lumière's invention is to have a prominent position in the programme at the Empire Theatre.

Institution of Junior Engineers.—By invitation of the directors, about 150 members of the Institution of Junior Engineers have paid a visit to the National Skating Palace in order to inspect the machinery there.

Communication with Lightships.—The Royal Commission on the subject of electrical communication with lightships is approaching the end of its prolonged investigation. The taking of evidence has been concluded, and the final report is expected to be presented after Easter.

Telegraphs in the North.—According to the *Elektrotechnische Zeitschrift* a new connection is to be made in the extreme north between the Russian and Norwegian telegraph systems. The new line will run along the coast of the Arctic Sea to Vadsö, in Norway, and the Russian portion is expected to be ready in the course of the summer.

Aerial Graphoscope.—Mr. E. S. Bruce is to give a demonstration of the aerial graphoscope at the Kensington Town Hall on Wednesday evening next. The apparatus is one in which the principle of the persistence of vision is made use of to secure a lantern image projected apparently in space, and effects are produced which are not otherwise obtainable.

The Red Lion-square Accident.—The adjourned inquest into the death of Mr. A. F. St. George has been concluded, a verdict of accidental death being returned. According to the evidence, Mr. St. George was carrying on experiments in connection with the manufacture of candles, and having practically filled a cylinder with various substances placed it over a gas furnace, when the explosion took place. There was no pressure gauge on the cylinder.

Personal.—We are informed that Mr. S. Sudworth, who for some years has had charge of the dynamo and transformer shops at Messrs. Johnson and Phillips, has resigned his position, and has been appointed works manager to the Consolidated Telephone Construction and Maintenance Company at Coventry. Before leaving Charlton, the staff and workmen with whom he had been associated presented Mr. Sudworth with a handsome clock as a testimonial of their regard and a mark of their good wishes for his success in his new field of work.

Electricity in Dental Practice.—Dr. Levitt E. Custer has been writing to an American professional paper calling attention to the advantages of electric heating apparatus in dentistry. He lays especial stress on the precision with which it can be controlled and regulated. There is undoubtedly much truth in this, and another advantage is the absence of waste products of combustion. As the total amount of heat required is not enormous, and the work required to be done is expensive and of high quality, the field would seem to be an ideal one for electric heating work.

The Telephone Service.—Messrs. Camm, Bagshaw, and Co., Sheffield, have forwarded to the local Press some correspondence with the National Telephone Company. For the company's new list Messrs. Camm, Bagshaw, and Co. gave their trade description as "steel and file manufacturers." For this the Telephone Company wanted to charge them 5s., on the ground that a business description should be confined to three words. Messrs. Camm, Bagshaw, and Co. said they could not put it shorter, and they would not pay. There the matter rests at present.

Diamagnetism.—The Amsterdam Academy of Science has received a communication from Messrs. H. A. Lorenz and J. D. van der Waals on Mr. L. H. Siertsema's criticism of Mr. Duhem's proof of the impossibility of the existence of diamagnetic bodies. The authors consider that Mr. Siertsema has shown that what Mr. Duhem actually proves is only that the old theory of Poisson, or any similar theory, is only admissible in explaining the properties of such a body as bismuth on the supposition that the magnetic susceptibility is not negative in character, but only less than that of the surrounding medium. As applied to Maxwell's theory, Mr. Duhem's reasoning fails.

Uranium Carbide.—In another note mention is made of the carbides of the cerite metals. Mr. Henri Moissan has also produced carbide of uranium, and says that when heated with excess of carbon in the electric furnace the carbide is a definite and crystallised one, corresponding to the formula U_2C_3 ($U = 240$). Cold water decomposes it, a third of the carbon being given off in the form of a mixture of gaseous hydrocarbons, of which three-quarters are methane, and very little acetylene. Hydrogen is also present. The remainder of the carbon produces a mixture of liquid and solid carbides. It looks as though this reaction might prove a typical one for the carbides of several elements.

Sparks and Tramlines. — It is remarked by *L'Electricien* that it is well known that interruptions of the circuit caused by dirt and grit on the rails of electric tramways are liable to produce a good deal of sparking as the tramcars pass, and that this can only be prevented by the constant use of sweepers. On the Rouen tramlines, where they have at present a mixed service of horse and electric tramcars, this has not been done, and the result is that the street boys having discovered the effect of a stone being put under the tram wheels have made a regular practice of putting small pebbles on the lines in the Rue Jeanne d'Arc for the pleasure of seeing the sparks when the tramcar goes by.

Telephones in France.—It is stated that the arrangements for extending the existing through telephone service between Paris and Marseilles on to Cannes, Nice, and Monte Carlo have been all but completed, and that it is probable that within the near future it will be possible to converse freely with the Riviera at any of the Bureaux de Poste in Paris. It has further been stated in a Dalziel telegram that negotiations are pending between the London and Paris postal departments, so that the London and Paris telephone may be connected with the French inland trunk wires. It is understood that the French Government is seriously considering the practicability of telephone communication between Marseilles and Algiers.

Exhibitions.—It is confidently stated that at the Swiss National Exhibition, which opens on May 1, the electrical exhibit will probably be the finest ever seen. As the authorities have 12,000 h.p. at their disposal for experimental purposes, it is evident there ought to be no difficulty in the way of doing something very big. A meeting of the British committee in connection with the Hungarian Millennial Exhibition at Budapest this summer has been held. The meeting was presided over by the Lord Mayor, and the subject of transport was discussed. It is announced in the St. Petersburg *Viedomosti* that the Russian Minister of Finance contemplates organising an exhibition of Russian products in London, to be held next year after the closing of the Nijni Novgorod Exhibition.

Cerium Carbide.—Mr. Henri Moissan having worked out the metals of the alkaline earths, has extended his research into the carbides formed by the metals of the cerium class in the electric furnace, and has communicated

Digitized by Google

his results to the Paris Académie des Sciences. Mr. Moissan has obtained a carbide of cerium to which he has assigned the formula CeC_2. When decomposed by water this does not give pure acetylene, like calcium carbide, but a mixture of acetylene, ethylene, and methane. (Something of this sort must necessarily occur owing to the higher valency of cerium.) There is also stated to be a residue of carbon compounds whose composition is not given. Of the alkaline metals lithium carbide has been prepared, and gives acetylene in the usual way.

An Interrupted Experiment.—The electrical engineer has many enemies, from the teredo, which ruins his submarine cables, to the mice, which devour his electric light mains. It has remained for Blackpool to furnish a new terror. The town of Blackpool possesses a menagerie, from which there recently escaped a porcupine. When recovered it was found to have devoured the insulation off two cables of a three-wire system, and to be desperately engaged on the internal strands. History does not yet say how the diet agreed with it. The *Pall Mall Gazette*, to whom we owe this interesting paragraph, has clearly not done justice either to the intelligence or the taste of that porcupine. It is obvious from its taking the trouble to bare both the wires that the animal intended to make a connection, and not merely a meal.

The Metric System.—The examiners of private Bills having decided that it would be contrary to parliamentary usage for the promoters of Bills to employ metrical measures in the specifications prepared by them pursuant to the Standing Orders, Mr. Arnold-Forster proposes to take the sense of the House upon the matter at the earliest possible opportunity. His probable method of procedure will be to give notice of an amendment to the Standing Order. In America they are prepared to go much further, for the secretary of the New Decimal Association has received information from the United States that a committee of Congress has under serious consideration a Bill to render the metric weights and measures compulsory in all official transactions, and it is reported that the majority of the committee are disposed to take some action. If the use of the metric system were mandatory in all departments of the Government, it is believed that the example would be followed in private contracts.

Trees and Wires.—The American supply companies seem to have a way of preparing trouble for themselves by taking insulated wires loose through the branches of trees. The insulation naturally chafes off. The *Scientific American* relates a case which happened in Brooklyn (New York), in which an arc light wire running through trees appears to have produced some pretty fireworks. The fire brigade were summoned, and their idea of a remedy was to pump water on to the trees. American firemen are bad to beat, but they did not succeed on this line. Ultimately they had to go to the supply company and ask to have the current switched off. It is said that the damage done to property amounted to £300. Probably this was the result of the heroic efforts of the brigade and their water, unless—and that is the only other supposition—live trees in America are estimated at £100 a piece. There is, unfortunately, no information as to what kind the trees were. There is such a difference between pine and poplar. But in Brooklyn streets it would be neither of those.

Motorcarts.—The Lord Mayor has presided over a meeting of the honorary council of advice of the International Horse and Horseless Carriage and Roads Locomotion Exhibition which it is proposed to hold this year at the Crystal Palace. Among those present were Sir David Salomons, Mr. Jacobs (president of the Institute of British Carriage Manufacturers), Major S. Flood Page, Captain Simonds (chief officer Metropolitan Fire Brigade), Prof. D. E. Hughes, Mr. de Lande Long (clerk of the Coachmakers' Company), Mr. G. T. Rait (chairman of the Crystal Palace Company), and Mr. E. Clarke. Sir David Salomons, in moving a resolution expressing the advisability of holding the proposed exhibition, remarked that since he introduced a deputation on this subject to Mr. Chaplin the Government had declared itself favourable to self-propelled conveyances, and regarded them as likely to solve in a measure the light railways question. He thought Mr. Chaplin was to be congratulated on having taken so much interest in the matter and on having promised to bring forward a Bill to deal with it. Mr. Jacobs seconded the resolution, and it was carried. It was announced by Sir David Salomons, who occupied the chair during the latter part of the proceedings, that Lord Kelvin had consented to join the honorary council.

An Accumulator Problem.—In the *Journal* of the Institution of Electrical Engineers there appears a communication by Mr. Desmond G. FitzGerald on the determination of the weight of dilute sulphuric acid to be allowed for in the construction of accumulators of which the effective capacity at a required rate of discharge is known. The steps in the solution of the problem are (1) to find the quantity of theoretical H_2SO_4 constituting an ampere-hour equivalent of this acid and multiply this by 2 and then by the number of ampere-hours of the effective capacity; (2) to find the quantity of water (Aq) required to produce with the calculated weight of H_2SO_4 acid of the percentage strength N; and (3) to find what additional quantity of acid of the strength N will in combination with the calculated quantity (Aq) of water give a residual acid of the percentage strength n. If Q ampere-hours be the effective capacity, and A the weight of H_2SO_4 corresponding to this capacity, then $A = Q \times 56{\cdot}4$ grains. Proceeding as indicated above, Mr. FitzGerald eliminates the intermediate quantities and ultimately arrives at a formula which gives the total weight of acid as equal to

$$A + Aq + (Aq \,.\, A + Aq^2) \div \left\{ \frac{100\ A}{n} - (A + Aq) \right\}.$$

The quantity Aq in this formula is, of course, determined in the second stage from the proportion

$$N : 100 - N :: A : Aq.$$

Diffusing Globes.—We have received a report by Prof. S. P. Thompson on the diffusing globes invented by Mr. Fredureau, of Paris. From the report and the description accompanying it, we gather that the globe is not unlike the old "dioptric diffuser" brought out by Mr. A. P. Trotter some 10 or 12 years ago. In some cases a hemispherical reflector is used above the lamp in conjunction with the diffuser, which is below. With this combination the results obtained by Prof. Thompson with a 16-c.p. lamp are as follows, the zero angle being vertically downwards:

Angle at which light was measured.	Amount of light with naked lamp.	Amount of light with reflector only.	Amount of light with reflector and diffusing globe.
0deg.....	8	17·5	34
10deg.....	8·5	17·5	24
20deg.....	9·25	18·75	22
25deg.....	10·25	15·2	16·25
30deg.....	11·5	15	12

These figures show that a strong local illumination can be obtained in this way, but we must protest against the claim that for effective purposes the light is doubled. In nearly all cases of interior illumination the walls require lighting as well as the floor directly under the lamps. Also the figures show that the reflector dome gives a better and more even

Digitized by Google

distribution of light without the diffusers. This globe, which will be useful for table lighting, can be obtained from Messrs. A. and E. Cohen, of 2, Bury-street, E.C.

Telephones.—The Flensburg Chamber of Commerce has issued a circular to the other chambers of the German empire with reference to the telephone question. The circular points out that in some foreign States, especially the Scandinavian countries, in which Finland, with its excellent telephonic system on the Swedish model may be included, telephonic intercourse has attained an extraordinary development such as is unknown in Germany. Admitting that the postal and telegraphic organisation in these northern countries is not so highly developed as in Germany, and that the telephonic development may have been influenced to some extent by the fact, yet this is a reason which as must only be considered of minor importance, and the immense progress in Scandinavia must be attributed to the low charges which have existed from the beginning, and which have enabled the public to take advantage of the telephone, not only in the smaller but in the very smallest towns. A comparison is again made between Schleswig-Holstein and Jutland, and it is remarked the cause of the non-development of the telephone in Schleswig-Holstein must not be sought for in its physical characteristics, nor in a want of enterprise on the part of the Schleswig-Holstein public, but must be attributed to the demand having been killed by the heavy rates of subscription and onerous terms imposed. The result is that the number of subscribers in Jutland, which is thinly populated and without any large towns or any district of importance, exceeds the number of subscribers in the large towns of the German empire, Berlin and Hamburg only excepted.

Formula for Condensers.—Prof. Harold B. Smith contributes a short note to the February number of *Electric Power* on the subject of the construction of a condenser. A given capacity is wanted, and it is required to find the size. Starting from the theoretical formula for the capacity, $k\ A/4\ \pi\ d$, where k is the specific inductive capacity of the dielectric, A the area of the plate, and d the distance between the plates, it follows immediately on expressing the capacity in microfarads that the required area, A, is given by the equation $A = 1{\cdot}1313\ C\ d \times 10^7/k$, where C is the given required capacity. The value of k of course varies from unity in the case of air to as much as 5 for mica. (It is a quantity by no means accurately determined for most substances.) As a practical example, suppose it is necessary to design a condenser having a capacity of 1·5 microfarads with a dielectric of oiled paper 4·3 mils thick and tinfoil 7 mils thick, since the value of k for oiled paper is 2·67, the equation given above becomes $A = 1{\cdot}1313 \times 1{\cdot}5 \times {\cdot}0043 \times 2{\cdot}54 \times 10^7 \div 1{\cdot}67$, or the area required is 69,400 square centimetres, or 10,759 square inches. In obtaining from this the number of plates of a given size, it is obviously necessary to remember that on the two outer plates only one surface is effective, so that one more plate is required than the formula would appear to give. It is stated that the capacity of a condenser of 65 plates made in this manner came out on testing by one method exactly correct, and tested in another way correct within 2 per cent. With reference to this absolute accuracy, it may be observed that in most tables of the values of k a very considerable margin is allowed in the figures.

New York Railways.—The *Electric Railway Gazette* gives an account of the evidence of Mr. David L. Barnes, consulting engineer for the Westinghouse-Baldwin combination, given in the rapid traction investigation before the United States Supreme Court Commissioners. So far as New York was concerned, Mr. Barnes advocated the use of a passenger car equipped with motors and hauling trailers, and expressed the opinion that such a train could be operated at a speed of 60 miles an hour between stations, if the stations were a mile apart. In case it became necessary, he said, two motorcars might be provided for a train, but he did not favour the plan of equipping every car with motors, on account of the complication in wiring and the greater first cost of rolling-stock. Where the trains were operated without switching, and there was no loop track, he advocated the use of a motorcar at each end of the train when more than one was necessary, so that the motorman could control the train from either end of it. He had examined the profile of the proposed underground road, and saw no difficulty in operating electric cars upon such a road, at an average speed for express trains of 40 miles an hour and 15 miles an hour for local trains. He calculated that a seven-car train (one motorcar and six trailers) could be brought to a speed of 60 miles an hour within 47 seconds on a level track, and within a distance of 2,700ft. To reach a speed of 40 miles an hour would require 32 seconds and 1,200ft. He expressed the opinion that there is no choice in the matter of the system of propulsion for the proposed underground road—electric traction, he said, is the only feasible method. The cost of changing the present elevated roads over to electricity Mr. Barnes estimated at 8,000,000dol., and he thought the saving in operating expenses which had been realised by the Chicago West Side elevated road would reach 25 per cent.

Electric Locomotives.—The French Society of Civil Engineers has been discussing a communication of Mr. H. de Grièges on "The Progress of Electric Traction on Railways." This related mainly to what had been done on the Chemin de fer de l'Ouest by the electric-steam locomotive "Fusée," and to proposals to construct a new one of much larger size. Mr. de Grièges, however, stated that besides hoping, in the course of the summer, to have two of the Heilmann locomotives at work, the company intended to start electric traction on a conductor system on a line between Saint Germain Ouest and Saint Germain Grande Ceinture. After a great deal of discussion on the points of weight and speed in comparison with the ordinary steam locomotive, Mr. L. Rey asked Mr. de Grièges if he could state what was the relation between the work done on the pistons and the work returned at the draw-bar in his engine. Mr. de Grièges said that an effective return of 67 per cent. was obtained. At this Mr. Rey was openly surprised, and remarked that the best locomotives on the Nord Railway usually averaged about 55 per cent. Mr. J. A. Pulin thought there must be some mistake in the figure given. In reply to Mr. Regnard, Mr. de Grièges stated that the steam-engine used was not of the Willans type, but more on the plan of the engines used in torpedo boats. Each of the six cranks was worked by a single piston rod carrying two pistons instead of three. Ultimately the discussion went over to the next sitting of the society when Mr. Bousquet said the efficiency of 67 per cent. corresponded to an efficiency of 90 per cent. for the steam-engine, 90 per cent. for the dynamo, and 83 per cent. for the motors. This, however, was the efficiency at the wheel and not at the draw-bar. When allowance was made for the work done in moving the engine itself, the efficiency came down to 39 per cent. Mr. Réné Varennes said the electric locomotive contained a locomotive boiler, a steam-engine with quite a number of cylinders, a dynamo, another steam-engine with two cylinders used to excite the magnetic field, eight electric motors with their commutators and brushes, not to mention the bearings. It seemed to be a combination of complications, in which were

Digitized by Google

united all the troubles of a fixed installation of electricity, an electric tramway, and an ordinary steam locomotive; and yet, Mr. Varennes complained, people had objected to the compound steam locomotive because it had four cylinders instead of two. After this, no one appears to have said any more.

The New Photography.—The interest displayed in the application of Prof. Röntgen's discovery to photographic purposes continues unabated. Nevertheless there seems little to note beyond repetitions and extensions of results already attained. Some time ago it was noted that the new radiations had been used to distinguish false pearls from true without removing them from their settings. Messrs. Abel Buguet and Albert Gascard, according to a communication made to the Paris Académie des Sciences, have ascertained that the same thing can be done with diamonds, as these are much less opaque to the Röntgen radiations than the heavy glass is that is used to imitate them. The new photography has also during the past week made its first appearance in a court of justice. In the course of a case at the Nottingham Assizes it was considered necessary to prove that an actress had suffered a displacement of the bones of her foot, and Röntgen photographs were put in and apparently used as evidence in support of the medical testimony. In the course of a lecture last week at the Society of Arts Mr. Campbell Swinton described an improved form of Crookes tube which he had employed for the new photography, and with which he had obtained superior results. In it the cathode plate was concave, so as to focus the cathode rays upon a point on the piece of platinum foil forming the anode. The foil was bent at an angle of 45deg. to the direction of the cathode rays so as to throw down the Röntgen rays, which in this case proceeded from the platinum, not the glass. The advantages of this tube were that it gave a sharpness of definition otherwise unattainable, and that there was less chance of the glass being cracked by heat. As to other points in the construction of the tube used, he said it must be made of soda, not lead, glass. Further, it must be exhausted to a very high degree, though what exactly was the best degree of exhaustion was uncertain. The best plan was to keep the tube connected with a mercury-pump, so that the exhaustion could be varied at will. He found that even a sealed-up tube would not retain the same exhaustion from day to day, owing to absorption of residual gases by the electrodes, condensation on the glass, etc. Mr. Swinton also exhibited an apparatus similar to what Prof. Salvioni, of Perugia, called a "cryptoscope," in which the fluorescence of a diaphragm contained in a tube is used to give a visible image of the "shadows" of the new rays. The material Mr. Swinton uses to make his diaphragm fluoresce is, however, barium platino-cyanide. At the close of the lecture, Prof. Dewar, who had presided, made some remarks, but refused to commit himself to any statement as to the theory of the new rays. Indeed, this matter seems to stand very much where it did. It may be noted that Mr. W. Lascelles Scott, of Forest Gate, has written to the *Times* to the effect that he has discovered that the Röntgen rays are capable of refraction under certain conditions, but unfortunately he gives no particulars. He also confirms the discovery already made on the Continent that the light from most fluorescent substances—for instance, platino-cyanide of barium, quinine, stramonium, fluoresceine, calcic sulphide, and that form of the old Bologna, or Canton's phosphorus, often utilised as "luminous paint"—contains a proportion of the new rays, or at any rate will, with a sufficiently long exposure, produce photographs through vulcanite and wood. Mr. Justice Wills has also written to the *Times* on the subject, but mainly to suggest that the proper name for the new process is "scotography." This is distinctly better than Mr. Le Bon's *lumière noire*. Mr. Scott would call the prints "vibriographs." The associations conveyed by this are anything but happy.

Oil Insulation.—Mr. Elihu Thomson has contributed to the New York *Electrical World* an interesting article on the dielectric strength of oils under alternating potentials. In the course of tests made under Mr. Thomson's direction, the fact was noticed that the striking distances of high potentials in insulating oils were in some way variable with the frequency of the current or potential waves, or upon the time during which electric stresses existed in a given direction through the medium, and this relation has been confirmed by other and later experiments. The general effect is found to be that discharges at low frequencies are capable of puncturing mineral oil layers up to from one-third to one-half the thickness of an air layer required to just resist puncture by the same discharges, while with high frequencies of equal striking distances in air an oil layer of one-thirtieth to one-sixtieth of the thickness of the air layer was sufficient to prevent discharges. At frequencies such as 125 per second a potential which would give $\frac{1}{2}$in. spark in air may puncture from $\frac{1}{3}$in. to $\frac{1}{4}$in. of oil between the electrodes, while at frequencies of 50,000 to 100,000 a layer of oil of $\frac{1}{4}$in. may resist puncture when the spark in air is as much as 8in. The high frequencies experimented with were such as were given by condenser discharges over an air gap, including a primary of a few turns, with a secondary of a single layer of some hundreds of turns immersed in oil. The discharges, in such case, are not continuous waves, but a rapid succession of oscillatory discharges with dead intervals of periods of inactivity intervening. The effect of carefully drying an oil was found to increase its insulating power. In these tests of the power of oil layers to withstand puncturing by high potentials a curious effect was noticed, which was that discharges under oil passed far more readily between balls than between sharp points. With balls of $\frac{1}{2}$in. diameter as terminals, and with low-frequency (125) potential differences, ranging from 100,000 to 150,000 volts, the space between the points could be one quarter that between the balls. The ratio between the length of spark in air and between sharp points in oil was 10 to 1 at 10,000 volts, and 8 to 1 at 15,000, while with balls these ratios fell to 2·4 to 1 and 2 to 1 respectively. When flat plates were substituted for the balls the striking distance in oil was still further increased as compared with the distance with points. The seemingly anomalous action of points under oil, so different from their action in gases or air, is certainly curious, and the usual injunction to avoid points and edges as conducive to electric discharge does not seem to apply in such media as oil, at least when the potentials are alternating and at ordinary frequencies. Mr. Thomson goes on to suggest, as a theoretical explanation of the phenomena, that only such part of the electrostatic field as is due to the ether is first established after electrification, and that the increase of such field due to the molecules of the substance, such as the interposed oil, is subsequent to the former. If this were so, the establishment of an electrostatic field at high rates in oils would present analogies with the case of magnetic fields in iron or metals. Some results of investigations communicated by Mr. P. Jaret to the Paris Académie des Sciences with reference to the behaviour of mica support this view. No explanation is given of the reversal of the conditions of discharge from points and balls. The free path of the molecules of the dielectric may have something to do with it.

CLARKE'S PATENT COAL-CUTTING MACHINE.

The adjoining illustration (Fig. 1) is of an electrical coal-cutting machine manufactured by Messrs. Rosling and Appleby, of Bradford, Yorks, to Mr. T. B. A. Clarke's design and patent. We are informed that several of these cutters have been in use at the Lidgett, Nostell, Astley, and Tyldesley collieries for the past two or three years, and have given general satisfaction. It is claimed that the machine will hole hard bind at the rate of a yard a minute, and that it will hole in any material and in any part of the seam. At Nostell Colliery the cutters hole to a depth of 4ft. 6in. in hard bind containing iron pyrites, over 100 yards being done in a shift. Two men are employed, who lay their own rails.

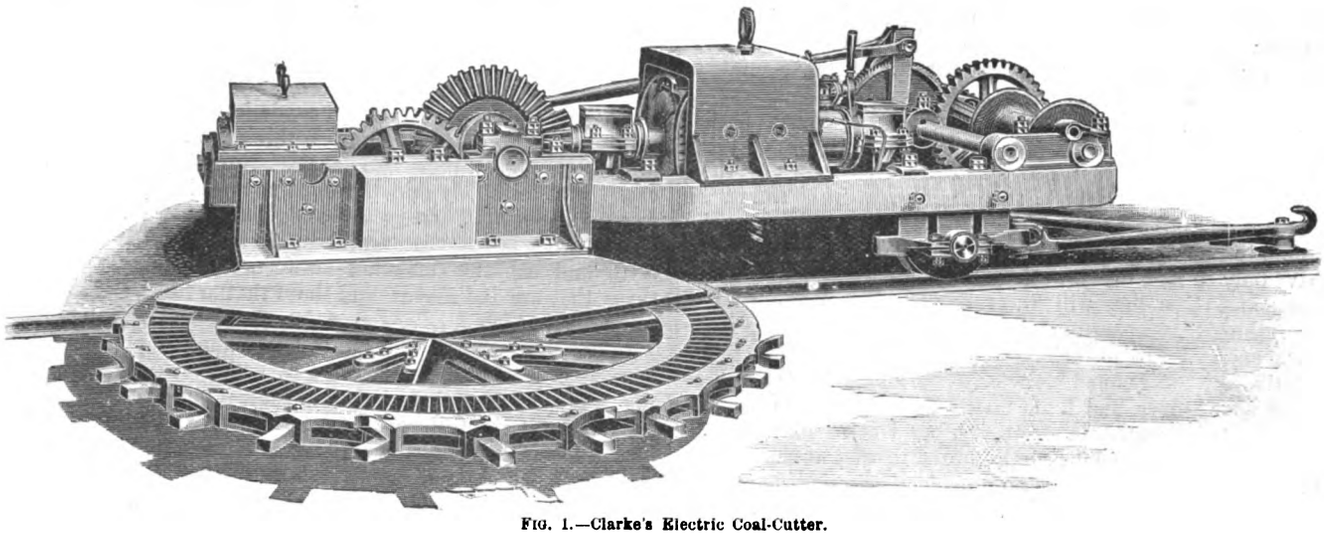

FIG. 1.—Clarke's Electric Coal-Cutter.

The machine is built of steel throughout, and is thoroughly enclosed and protected, being practically unbreakable. The motor is of iron-clad type, and is specially designed for the work, having the armature and commutator enclosed in a gas-tight casing, which is strong enough to thoroughly protect them from injury either by blows or other rough usage, or even a fall of the roof, and also from dust and dirt. A special brush gear is fitted to these motors which renders them sparkless. It will develop up to 20 h.p. at an emergency, but usually the work only requires from 7 h.p. to 10 h.p. The current is supplied at a pressure of about 400 volts, so that the motors can give off from 80 to 90 per cent. of the power supplied to the dynamo, half a mile away at the pit head. To colliery owners an important feature of the machine is the cheapness of working, which has been amply demonstrated at the various collieries where it is employed, as much as 10d. per ton, it is stated, having been saved over hand holing in a seam 3ft. thick. The dynamo manufactured by the same firm for driving the coal-cutter is also of special design, and made to stand the very heavy alterations in load which are bound to occur in this kind of work.

The second illustration (Fig. 2) shows the same firm's new type of dynamo machine, with circular bedplate and steel magnets. Great care has been taken in the design of these machines, especially as regards efficiency, durability, and small rise of temperature during continuous running.

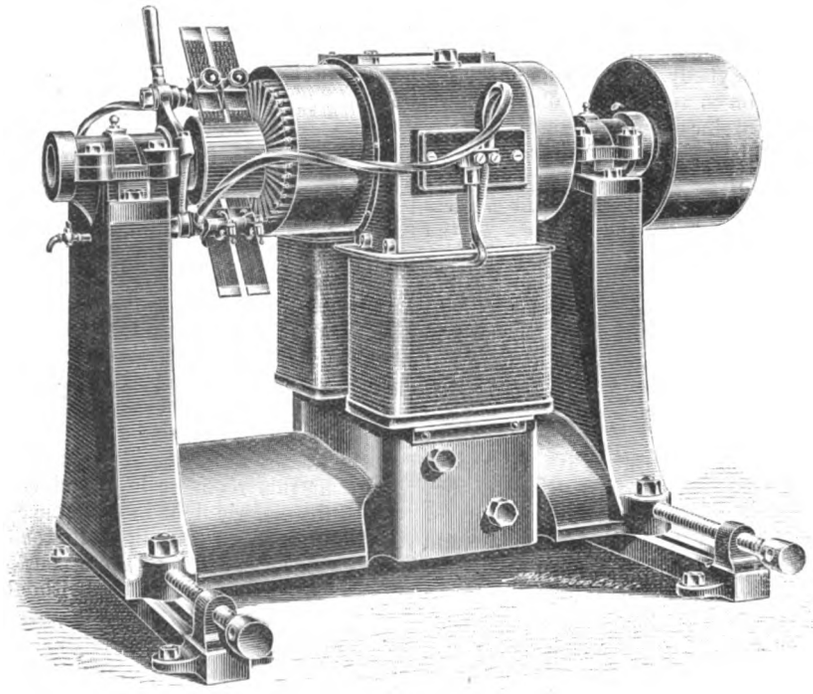

FIG. 2.—Dynamo used to Drive Coal-Cutter.

ELECTRICITY IN CONNECTION WITH BUILDING.

LECTURE BY MR. W. H. PREECE, C.B.

(Concluded from page 265.)

But in some places private enterprise produces equally great effects; for instance, in Newcastle, there are two companies competing against each other, and I was quite surprised only last week to receive notices that the rate of 4½d. per unit at which they were supplying current to our post office there, and subject to a discount of 10 per cent., was reduced still further by increasing the discount of 10 per cent. to 20 per cent. The result is that we are paying in

Digitized by Google

Newcastle less than 4d. a unit for exactly the same material, if you can so call it, for which you are paying 8d. per unit. Of course, that is due to the fact that coal is cheap in Newcastle and dear in London. Swansea is a town near the coal district, and Swansea is a town where they have proposed not alone to supply electricity for electric lighting purposes at night, but also to utilise it for working their tramways by day; and if this scheme were carried out (I am not sure that it will be) it would mean this, that by having a continuous supply during 14 or 15 hours of the day they would be able to reduce the price to their consumers to probably as low as 3d. a unit. Now, that means that, while 8d. a unit is equivalent to gas at 4s., 6d. a unit is equivalent to gas at 3s., and 3d. a unit means a light equivalent to gas at 1s. 6d. That is probably what would be found in some of those towns in the coal districts which are able to apply their energy, not only for light, but for the movement of trains. I am not speaking idly on the subject, for everybody who wants to know what energy costs and what people pay for it have only to look every week in the columns of the technical Press and there they will find full records week by week of everything that appertains to the cost of production of electrical energy. One of the first questions asked is, "What is the relative cost of gas and electricity?" I have told you I was a gas shareholder, and I am interested in gas—I do not tell you I am interested in electricity, but I leave you to guess. My experience is, and I have indicated it, that at the present moment practically there is no difference between the cost of electricity and the cost of gas. Anybody can verify this for himself. If he has not got gas in his house or his office, he has some friend who has, so he has only to compare his electric light bills and his gas bills and he will find whether there is any great difference between the two. Now, I have seen a great many of these accounts, and I have seen great differences between the two. Sometimes the electrical light bill is less than the gas bill—often it is more than the gas, but if you take throughout the country the figures that are published every week, you will find that on the average there is no difference between the price of gas and the price of electricity. That is now. But, as I told you, the cost of production is lowering, and the result will be that the time is not very far distant when electricity will be considerably cheaper than gas. Of course, in my mind, I am comparing the ordinary burner with the ordinary electric lamp. The incandescent gas has recently come in, and that is going to produce a considerable change. There is no doubt that the incandescent gas gives you a very brilliant and a very beautiful light, and I cannot conceive anybody in his common senses who could resist the temptation to replace the old ordinary burner with the new beautiful incandescent lamp. In the first place, it gives a more brilliant light than the old burner; in the second place, it reduces the cost and the expenditure; and in the third place, it diminishes considerably the defects of gas, the principal consideration being the freshness of the air we breathe. Many people say—it has been said to-night—that the incandescent gas is going to interfere with the progress of electric light. I do not think so; and I do not think that the introduction of the electric light is going to interfere with the progress of gas. Each has its function. The function of gas is heat and power, not light; the function of electricity is light; and the function of the incandescent gas is to teach the public the benefit of a beautiful light. When they find that this beautiful light carries with it all, or nearly all, the objections of gas, it will mean that their next step will be the displacement of gas in any form for light, and the use of electricity. But gas being in the house, and gas able to be used for heating, gas will be applied to heating purposes, and so the business of the gas producer will not be affected, and, which is much more important, the dividends of the gas shareholder are not going to be diminished.

Now, with regard to lamps. One important feature of the electric light is the character of the lamp that is used. There is nothing more simple than the electric lamp. It simply consists of a very fine thread of carbon, which is contained in a glass bulb from which all the air or gas has been extracted. It is, in fact, a vacuum, but there are some remnants of gas left in that vacuum. These remnants are in reality a hydro-carbon gas, and in that hydro-carbon gas the filament will remain alight for some time. If this lamp were not a vacuum—if there were air there—the filament would be quickly consumed; the oxygen of the air would combine with the carbon which would generate carbonic acid and the thread would disappear; but being in a vacuum and in a very fine atmosphere of hydro-carbon, the result is that it burns for 1,000 hours or more. It is not combusted; it undergoes a certain disintegration on the surface, and through some electric action the particles of carbon of the thread are scattered and they cover the glass surface of the globe and dull it in course of time. These lamps were for 14 years the property of a company who, owing to the possession of a patent, held the monopoly, and the price charged was a pretty considerable one. The patent has expired and now the manufacture is open to all the world. The result is that we are flooded with lamps—lamps made in Germany as well as lamps made in England, and I think you all know the difference between those two labels. Now they have become cheap, and somebody said the word cheap simply meant the word "nasty." There was no doubt that we have been flooded with lamps that are cheap and nasty; the difficulty is to find out the difference between those that are good, those that are indifferent, and those that are bad. This is a subject to which I have devoted a great deal of attention. I cannot show you the tests now, but I want to point out to you the general idea of a method by which we can determine the quality of lamps before they are actually used. A lamp is supposed to have a life of 1,000 hours—that is, it ought to have a life of 1,000 hours—but we can in 1,000 seconds let it pass through a certain stage of its existence which, if carefully recorded, will give us the characteristic of the lamp, that will tell us in a few minutes its whole history. I cannot go through the process now because it involves a considerable amount of care, but I will show you what the process is. I switch the current on to this lamp and you see it gives the normal quantity of light. I now put on an increased current and this instrument—a voltmeter—indicates the voltage of the current passing through the lamp. You see not only is the brilliancy of the light increasing rapidly, but this indicator shows that the voltage is increasing too. If we had a photometer measuring the light at the same time as we are measuring the current and the E.M.F., we should have all the conditions that determine the life of a lamp. You see what a beautiful thing an electric lamp can be if we could afford to pass through it as much energy as is going through this lamp now. It is an ordinary 10 candle power lamp, and is probably giving 100 candle-power or more. Now it has broken at a voltage of 250. That lamp has passed through a history which, if carefully recorded, will give us all we want to know about that lamp. That is the test we are applying in the Post Office to all the lamps we can get hold of, and the result is that we shall soon be able to submit to the public a test that will enable us to select the bad from the good and the indifferent from both. Such is the lamp at our disposal for the purpose of introducing light into our buildings, and a lamp that has this particular merit that it does not vitiate the air we breathe. It is a lamp that we can put where we want it; it is a lamp that we can use when we want it; it is a lamp that we can apply to the decoration of our houses; it is a lamp that lends itself to the artistic tastes of the ladies of our households (the most important and particular factor in everybody's household); it is a lamp that gives us light by the consumption of energy without doing any harm whatever; and when we have that energy supplied to our houses at a rate of about half the cost of gas, who is there in this room or in the city of London who will not adopt the electric light in preference to any other?

Well, there are difficulties in the adoption of this light—for instance, the fitting up of our buildings. You cannot bring electricity into a house without there being a certain amount of danger. It is the same with gas, it is the same with fire, it is the same with candles, and it is the same, only much more so, with the common match. However, electricity, being the least dangerous of them all, still possesses danger—danger to person and danger to buildings—and here our Government departments and our insurance offices come in, and they supply us with rules and regulations by which, if we follow them, we ought to possess or obtain in our buildings the greatest possible security both to person and from fire. But, somehow or other, we all of us love, if we possibly can, to do the insurance company and the Board of Trade, and we want to do things cheaply. We put our work in the hands of the

Digitized by Google

contractor who will do it at the lowest possible price. We do not take the trouble to have our work properly inspected by officers of the insurance companies or by those competent people who are to be obtained all over the country for the small commission on which the poor architect and the carpenter live—namely, 5 per cent. on the work that is carried out. The absence of this inspection has led to a good many troubles. However, notwithstanding all this, the number of accidents in this country is ridiculously small; and of the thousands of fires that take place, the number of fires due to electricity numbers mere units. I think last year it was only three or four throughout the whole country, while the fires from other causes numbered thousands.

The cost of wiring is coming down, and my experience in the Post Office, where we are wiring-up buildings all over the country as fast as we can induce the Treasury to give the funds, bears out this statement. In the General Post Office there are no less than 10,000 lamps supplied and lighted every day by machinery that we have in the building. So it is all over the country: Manchester, Leeds, Birmingham, Glasgow, Liverpool, Bristol, and all our great places are being fitted up with the electric light, and we have no difficulty in getting the funds for doing so Well, now, the cost, as I said before, is going down. At one time the cost of wiring a building was as much as £3 per lamp. I have known it done for less than £1 per lamp; the average is a little more. The cost of wiring depends entirely on taste and on the money expended in fittings. You can spend £50 on a single electrolier for your drawing-room. An electrolier may be made of any form or shape you like, and you can spend as much or as little money on it as you please; and if you are satisfied with plain, simple fittings there ought to be, there is no difficulty in fitting-up a building at £1 or £1. 5s. per lamp.

Then comes the mode of distribution. I have a board there which shows how the energy can be distributed through the house. It represents a plan of a house with four rooms, and each room can be put on separately and independently. The one charm of the electric light is, as I said before, that you can put it where you want it, and you can use it when you want it. You can use it for any purpose whatsoever, and my friend Mr. Probert, who is here, will show you a doll's house which he has constructed and fitted throughout with the electric light. I merely show you that to illustrate how simply electric light can be applied to any purpose. Could you do it with gas, could you do it with candles, or with any other mode of producing illumination excepting electric light? We can also tell exactly the amount of light to be applied to these diffe rent purposes. There is an extremely simple law that enables you to determine exactly the number of lamps or the amount of light you want to apply to any particular room or space, and it is simply this—that if you take one square foot of floor surface you want to expend on it an energy of one watt per square foot. A watt means really a measure of the energy that is expended in a lamp. Now, each of these lamps round this room is what is called a 16-candle lamp, and each lamp absorbs 64 watts. There are 746 watts in a horse-power; a horse-power will therefore supply energy for about 11 of these lamps. As each 16-candle lamp absorbs 64 watts, and as a rule in dwelling-rooms you have your lamps fixed about 8ft. above the floor, a 16-candle lamp will well illuminate 64 square feet. So that if you have a room of whatever size it may be, and you allow one watt per square foot of surface for a lamp 8ft. high, you have simply to calculate the number of watts for the whole area of the room; and if you cannot put your lamps 8ft. from the floor, but as they are here, about 35ft. high, you simply have to take the square of the distance and you can calculate to a nicety the amount of light required per square foot. Now, this room at the present moment is not illuminated to one watt per square foot. I know that by the ease or the difficulty with which I can read my own writing on white paper; but there are instruments called photometers that measure with extreme accuracy the illumination of a surface. By following this simple calculation, you are able to determine exactly the number of lamps that can be used and the expenditure of energy they absorb.

But there comes a difficulty; what is the reflective power of your walls? If your walls are painted white, half the number of lamps will give you the same light, but if architects will insist on panelling up their rooms with dark oak or teak panels, and put up marble pillars and pilasters, put in dark-green wall paper, and decorate their ceilings in a heavy manner, why, then, you must expect that the poor electrician will recommend to them a greater consumption of energy. There can be no doubt whatever, from experience, that with light distempered walls, as we are now adopting in our post offices—colouring the ceilings white and the walls as light as they can be—we get twice the amount of light that we should obtain if we were to follow the dictates of some of the æsthetical architects of the present day.

You should put your light so that it shall not offend the eye. The eye is the most wonderful, the most delicate, the most beautiful machine and apparatus that ever was designed or created. If there is anything that settles the point whether the human being is the result of design or of a concatenation of circumstances, as some people assert, the eye with its delicate mechanism is sufficient at once to bring it within the region of design. Automatically, the eye adapts itself to the amount of light that there can be available for it. Our ancestors were perfectly satisfied with the most horrible rush-lights. Nothing more appalling than the mode in which our grandfathers lived we in the present day can scarcely conceive. I can remember the time when we had moulded candles, and when the servants came round every hour and snuffed those abominable candles. Our theatres were lighted up by flambeaux. There were great torches suspended at the sides of the stage, and I remember reading of one man who said there was nothing he enjoyed so much in the theatre as the smell of the flambeaux.

Now, see what we have got. Look at this hall; and yet I am sure that we see very little better than our great-grandfathers who dined at the Carpenters' Hall under the influence of a tallow dip, for the simple reason that the eye adapts itself to the amount of light that is available for it. And that is why it is the greatest mistake in the world to place with the reach of the eye the bright and brilliant thread of one of these electric lamps. It dulls the eye If you come into a lighted room from the bright sunshine it looks dull, because the pupils of the eye are expanded by the brilliancy outside, and so it is that one has to study the eye in arranging the decoration of a room. The first law is, "never let the eye be offended by the brilliancy of the incandescent carbon filament." This is carried out to a large extent in nearly all our buildings. There is one of the banks in the City of London during the last week which has been lighted, not by the direct light from the lamps, but by reflected light of white walls, and I am told the effect is very beautiful.

So much for electric light. That is not the only purpose to which electricity can be applied. Electricity generates light because it generates heat. The only reason why these lamps show light so brilliantly is because they are heated to great brilliancy. The current passing first of all produces heat before it produces light. It is now being used to a very large extent for other purposes. Here is what is called a radiator. I happen to have in the Post Office a rather large room, and I found that my single fire-place during the cold weather was not sufficient to maintain the temperature of the room, so I had one of these radiators. The current passes through a wire that is behind the metal screen and becomes heated; not so hot as to become light, but quite hot enough to radiate heat, and the heat generated by the radiator is quite sufficient to raise the temperature in my office from 54deg. to 60deg., and it maintains the temperature of my office constant; so electricity can be applied to warming one's apartments. It can also be applied to boiling water. Here is a small kettle; I simply attach the block to the contrivance, and in about 10 minutes the water will boil. To be exact, it is worth knowing that it takes just 12 minutes to boil a pint of water, and it costs, with your energy at 6d. a unit, a farthing. Here is also an egg-boiler; but not only can you use electricity for making tea, for boiling water, for cooking steaks, chops, sausages, and all that sort of thing, but you can use it for no end of purposes—curling-tongs, flat-irons, and so on. We use it in the Post Office for heating up our wax. The quantity of sealing-wax used in a post office is marvellous; I cannot tell you how many tons are used per annum, but the consumption of gas and firing to maintain the heat to melt this wax is very considerable, and

Digitized by Google

now, in Leeds, we have introduced electricity for the purpose so far with success.

We can also use this energy for producing power to produce motion in machinery; and one of the most useful purposes in hot countries or in warm weather is to move fans, or in India for moving the punkahs. In engine-rooms and workshops fans not only produce great circulation of the air, but extract the air also and maintain ventilation. Then, again, it can be used for working pumps, and it is used for working lifts. In London there is one near Bond-street, close to the electric light station, there is one in Brighton Town Hall, and in several other places there are lifts worked by electricity We are introducing the current for lifts at our post office in Leeds. You can use it for knife-cleaning, it is used a great deal for printing machinery, and there is a very ingenious thing, one of the latest developments invented—viz., a deck-planing machine. What with its ability to supply us with the purest and cleanest light, with the means it gives us to warm up our buildings and to supply us with means of cooking and looking after our creature comforts, what with its power to enable us to ventilate our chambers and to cool the atmosphere in heated climes, I think we must say that electricity possesses a superiority over all other forms of energy. In dwelling-houses, in offices, it adds to the health of our people, in shops it is almost imperative, in workshops it is the greatest comfort in the world to the worker—it improves his health and enables you to get more work out of him—and in theatres and places of amusement it enables everybody to go with comfort to himself and to everybody else. In the days of gas a visit to the theatre invariably resulted in a headache; now, with the electric light, nothing of the kind occurs.

When you look at some of the pictures of the past—only two or three years ago there was a picture in the Royal Academy of a Highland chief keeping his court in his house, supported on each side by stalwart servitors holding torches, the floor covered with heather, and there he and his attendants sat at dinner. Compare the position of the Highland chief and people of rank in the olden times, with their stinking, flaring torches, with the comfortable bourgeois of the present day in his suburban residence, whose rooms are clothed with elegant Turkish and Oriental carpets, whose walls are decorated with the highest efforts of art, and whose living-rooms and bed rooms are lighted with the purest and most simple form of light. So we come to the conclusion that at any rate, however well our great-grandfathers saw, we see with ten thousand times greater comfort; and we have succeeded by admitting these forms of energy into our premises in doing something that has added to the happiness and to the comfort of us all.

On the proposition of SIR ARTHUR ARNOLD, a hearty vote of thanks was passed to Mr. Preece for his lecture.

NOTES ON STEAM SUPERHEATING.*

BY WILLIAM H. PATCHELL.

(Concluded from page 241.)

Hick, Hargreaves, and Co.'s Superheater.—By the courtesy of the makers, the author has been favoured with the following particulars and tests of their superheating apparatus in a mill at Bolton. As shown in Fig. 4, the apparatus consists of a nest of U tubes, bent to a large radius at the bottom, which are placed at the back of a Lancashire boiler where the hottest gases from the flues impinge upon them. The box containing the tubes is divided down the middle by a vertical diaphragm, so that the saturated steam entering at one side passes down and up through the tubes, and leaves superheated at the other side. A by-pass valve is arranged to regulate the flow of steam through the superheater, because only a portion of the steam from the boiler is intended to be superheated. The Lancashire boiler to which the superheater is applied has a grate surface of 39 square feet; the heating surface in the boiler is 1,195 square feet, and in the superheater 120 square feet. The area of passage through the superheating pipes is 22 square inches. The boiler pressure is 100lb. per square inch. The test showed an economy in water of 9·6 per cent. per indicated horse-power per hour with superheating and 19 per cent. of coal. In the tests a portion only of the steam was superheated.

McPhail and Simpson's Superheater.—This apparatus is the invention of Mr. Hugh McPhail, and is manufactured in Wakefield by McPhail and Simpson's Dry Steam Patents Company. It consists of two parts: the superheater proper, and

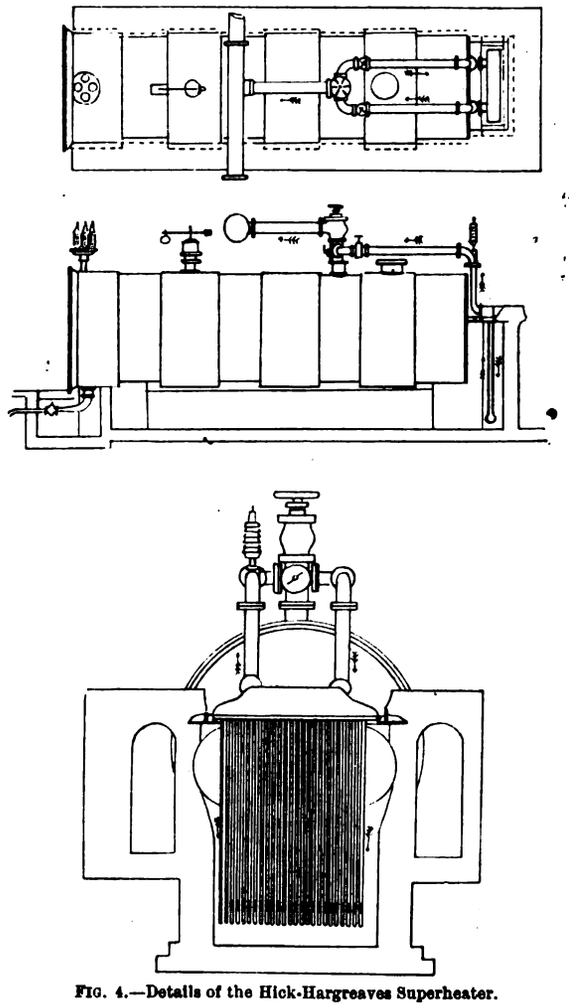

FIG. 4.—Details of the Hick-Hargreaves Superheater.

the steam-generator of radiating tubes, which distinguishes it from all other plants. As applied to a Lancashire boiler (Figs. 5 and 6), there are two nests of vertical steel tubes, expanded at top and bottom into cast-steel boxes, or "headers," as they are called in water-tube boilers; these nests are placed preferably at the back end of the internal flues of the Lancashire boiler,

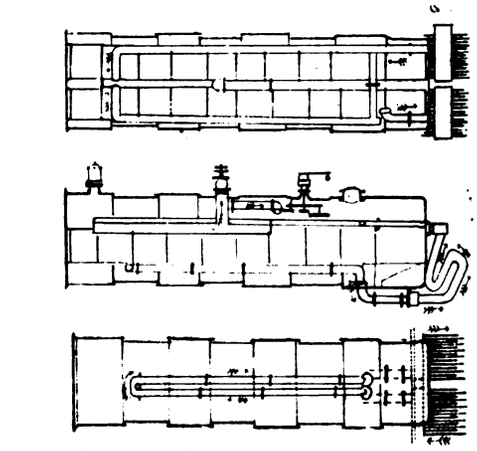

FIG. 5.—McPhail and Simpson's Superheater.

in the down-take, where the furnace gases impinge on them and pass between them. One of the top boxes is connected to the usual anti-priming pipe in the boiler, and the corresponding bottom box is connected to a block, which passes into the bottom of the boiler, and from which a copper pipe runs along the bottom of the boiler under the internal flues to the front end, and thence back again to the rear, where it passes out of the boiler and into the other bottom box. The second top box is connected to another copper pipe, which runs along the boiler over the internal flues, just below the water-line, and ends at the main steam stop-valve. The

Digitized by Google

course of the steam is from the anti-priming pipe to the first top box, then down through the superheating tubes to the first bottom box, whence it enters the boiler, and passing through the lower copper pipe gives up part of its superheat to the surrounding water, before leaving the boiler and entering the second bottom box. It is then further superheated in passing up through the second nest of tubes; and thence passing through the second top box into the upper copper pipe in the boiler, it again parts with some of its superheat, before finally leaving the boiler at the steam stop-valve. The final degree of superheat depends upon the proportion of the superheating tubes to the radiating pipes. The function of these radiating pipes is most important, as they give off to the water in the boiler the superheat which might be dangerous in the engines at times of heavy firing; and, when the fires are green after cleaning and the flue gases low in temperature, they prevent any possibility of the superheater becoming a condenser. They thus tend to keep regular the amount of superheat in the steam as it leaves the boiler. In its complete form this superheater has been tested and fully reported upon by several engineers in this country, among whom may be mentioned Messrs. Crossland and Michael Longridge. The results of some recent tests made by M. Armengand, at the works of Messrs. Isaac Holden, with a Lancashire boiler 28ft. long and 8½ft. diameter, with two internal flues 3ft. 3¾in. diameter, heating surface 2,287½ square feet, grate area 39 square feet, showed an equivalent gain of 30·9 per cent. in the weight of water evaporated per pound of coal when the superheater was used.

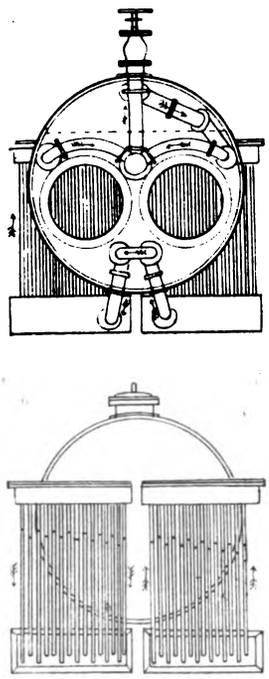

FIG. 6.—McPhail and Simpson's Superheater.

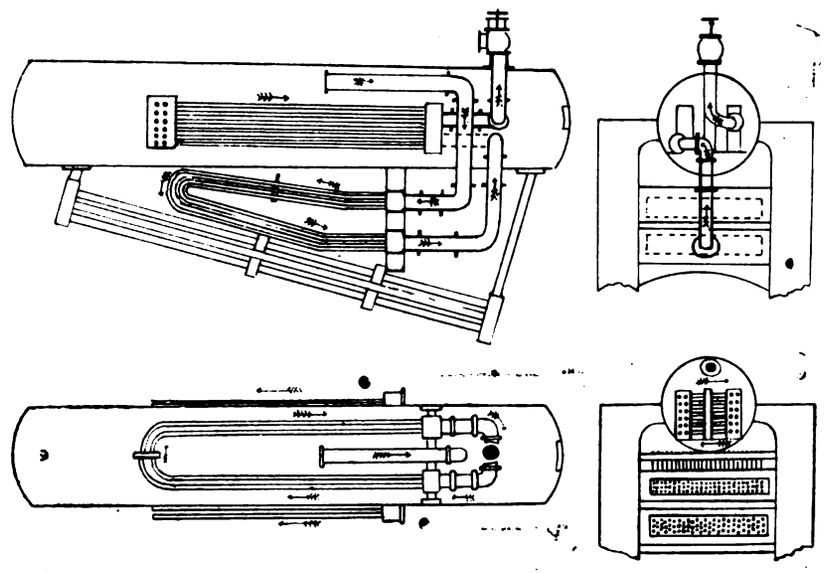
37·7 square inches, and through steam stop-valve 28·27 square inches. Complete tests of one boiler were made by Prof. Kennedy before and after the superheating apparatus was fixed, and the principal results with and without the superheater are given below:

	Without.	With.
Date of trial, 1893	June 20.	Oct. 17.
Actual water evaporated per pound of coal, lb.	8·89	9·65
Evaporation per pound of coal from and at 212deg., lb.	10·50	11·47
Evaporation per pound of carbon value, lb.	10·30	11·22
Coal burnt per hour per square foot of grate, lb.	11 3	15·5
Coal burnt per hour per e.h.p., lb.	4·74	4·12
Water per hour per e.h.p., lb.	42·1	39·7
Coal per kilowatt-hour, lb.	6·35	5·5
Water per kilowatt-hour, lb.	56·4	52·8
Efficiency of boiler, per cent.	68·4	74 9

The temperature of the steam in the main steam-pipe was 7deg. below the temperature of saturated steam when the superheater was not in use, and it was about 9½deg. above that temperature after superheating.

The superheat was practically lost in the range of steam-pipes between the boiler and engine. The increased capacity and ease in working of the boiler have been as marked in its subsequent use with the superheating apparatus; in regular work it is evaporating about 50 per cent. more than heretofore. At first the author had some misgivings as to incrustation forming in the superheating tubes from the priming water; but from examining them closely on several occasions after a run of 4,000 hours and more, and finding them perfectly clean, he is satisfied on this point. The top box, by its increase in area over the steam-pipe, gives a period of comparative rest in the flow of the steam, and acts as an efficient separator for the water or scum carried over. A steam-trap fitted to the box discharges any such accumulation regularly, thus preventing its being carried into the superheating tubes. The bottom box is also fitted with a trap to intercept any leakage from the steam stop-valve when the boiler is shut in. The first apparatus proved so satisfactory that a second was applied to the companion boiler in 1894, when the effect of the superheated steam in the pipes began to be marked by a decrease in the discharge from the drains and in the leakage from joints.



FIGS. 7 AND 8.—McPhail and Simpson's Superheater.

Another series of six tests made at the Kinleith Mills, Currie, Midlothian, on Lancashire boilers, each 28ft. long and 7½ft. diameter, having a heating surface of 920 square feet and a grate area of 36 square feet, showed an equivalent of 35·4 per cent. in the water evaporated per pound of coal and 2·6 per pound of combustible. This type of superheater was adopted by the author in 1893 at the Maiden-lane station of the Charing Cross and Strand Electricity Supply Corporation, but had to be considerably modified to suit the Babcock and Wilcox water-tube boiler, as it was found possible to put only one set of superheating tubes in the limited space between the top of the water-tubes and the underside of the drum, and only one set of radiating pipes in the drum, so that the arrangement represents only one-half of the complete apparatus as applied to a Lancashire or double-flued boiler. The arrangement is shown in Figs. 7 and 8. The saturated steam is taken from the anti-priming pipe to the upper box of the superheater, whence it passes down through the superheating tubes to the lower box, thence up into the radiating pipes in the drum, and through these to the steam stop-valve. The principal dimensions of the Babcock and Wilcox boiler are: 9×9=81 tubes, 18ft. long and 4in. diameter; total heating surface about 1,827 square feet; drum 23½ft. long and 4ft. diameter; width of fire-grate 5ft. 6in.; total grate surface 34·4 square feet. The principal dimensions of the superheater are: 75 superheating tubes of 1in. diameter, heating surface 355 square feet; 12 radiating pipes of 2in. diameter, heating surface 174 square feet; area through superheating tubes 58·9 square inches, through radiating pipes

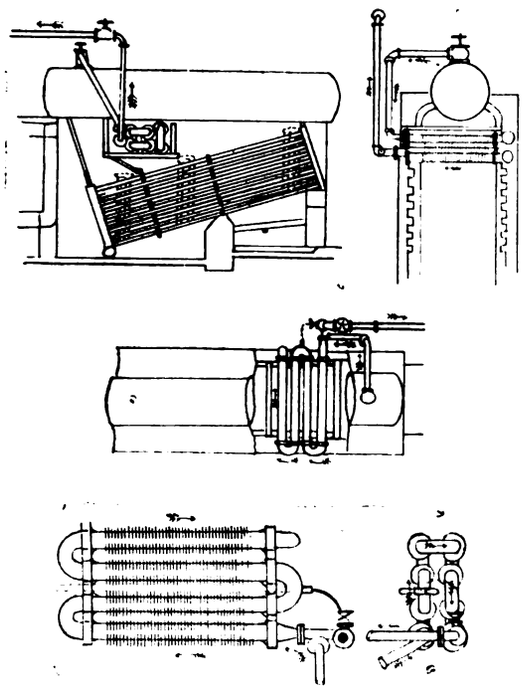
Induced Draught.—The duty of the boilers having been increased to the above extent, and the priming difficulty being quite overcome, the only limit to the evaporation was the chimney draught. As the two boilers were fitted with an independent flue and chimney, they lent themselves readily to an experiment in this direction. Having considered several schemes of forced and induced draught as an auxiliary, the author finally decided on putting a fan in the flue at the back of the boilers. As there was no space available for any form of economiser between the boilers and the fan, no attempt could be made to diminish the loss from heat in the waste gases. The gain sought for was in the direction of increasing the capacity of the existing boilers, so as to render steaming independent of the natural effects of foggy or heavy weather, and by working the boilers at a higher rate to diminish the proportion of radiation losses, which are practically constant at all loads. The fan selected is a 72in. single inlet, made by Messrs. G. E. Belliss and Co., and driven direct by one of their tandem compound self-lubricating engines, having cylinders 3½in. and 6in. diameter and 4½in. stroke, working at 150lb. boiler pressure, and running at 300 revolutions per minute. The engine and fan were put in somewhat large for

Digitized by Google

the estimated work, in order to secure slow speed and quiet running, with the result that within a few feet of the fan it is impossible to tell by the sound whether it is running or not; this is a marked improvement on many fan engines. A draught in the flue at the fan inlet equal to a 2in. water-gauge has been easily maintained. The usual method of working is to work the boilers on natural draught at times of light load, and then, as the load increases, to start the fan, close the by-pass in the flue, and work steadily at 1in. water-gauge. With this draught the superheater tubes are continually bathed in incandescent gases, but not the slightest trouble had been experienced with them. In order to test the thorough reliability of the tubes, and in view of the fact that trouble was most likely to arise, if at all, when getting up steam, one of the boilers was shut in, and the steam let down day after day for some weeks and then raised again with the induced draught; and there was an entire absence of any signs of irregularity or trouble. When the boiler is steaming freely, an iron bar inserted through the brickwork to a point near the ends of the tube soon becomes red hot, and the temperature as taken by a platinum coil pyrometer is about 900deg. F. At this temperature it appears to be of little importance whether the cooling agent is water or steam, so long as the circulation is kept up. This circumstance is most interesting in view of Mr. Durston's Devonport experiments, reported in his presidential address to the Institute of Marine Engineers, as to the permissible limit of temperature in a tube or tube plate, which he places at about 750deg. F.; and in view also of the grave doubts that are frequently expressed as to the safety of steel tubes exposed to furnace temperatures without a perfect circulation of water on the other side of the metal. What temperature the tubes actually reach the author is unable to state, but the steam coming out of them is over 600deg. F. The tube plates would be lower in temperature than the outer ends of the tubes, because the gases are drawn downwards and away from the plates by the draught. No trace of leakage at any one of the tube ends has yet appeared.

Schwoerer's Superheater.—The superheater illustrated in Figs. 9 to 11 is the invention of Mr. Emile Schwoerer, of Colmar, Alsace, who was for some time private secretary to the late Mr. G. A. Hirn. It was Mr. Hirn who first took up superheating seriously, and it is due to his energy that so much has been done with it in practical working in Alsace. Mr. Schwoerer's improvements were in the direction of reducing the space occupied by the apparatus, and he attained this end by employing a coil of pipe with gills on them both inside and outside, thus getting large surfaces in a small bulk. Regulation of the superheat by deflecting the hot gases away from the tubes, rather than by varying the proportion of the total steam passing through the tubes, is due to Mr. Schwoerer. By the courtesy of Prof. W. Cawthorne Unwin the author is enabled to give the tests of Schwoerer superheaters in Alsace, some of which were carried out by himself and others by Mr. Walther Meunier, engineer-in-chief of the Alsatian Association of Steam Users. The boilers were of the Elephant kind, with Green's economisers. The saving effected in the coal varied in the 12 different trials from 17·6 up to 25 per cent., and the economy in steam from 11 to 20 per cent. An application of the Schwoerer superheater has been made by Messrs. James Simpson and Co. to a Babcock and Wilcox water-tube boiler at the Grand Junction Waterworks, Kew.* The arrangement is shown in Figs. 9 to 11. The boiler is of the same size as those fitted by the author with McPhail's apparatus at Maiden-lane. Full details of the trials unfortunately cannot be obtained, but the saving effected is satisfactory. Tests were conducted by Mr. Osbert Chadwick before and after the superheater was fixed, and showed a saving of from 6·05 to 10·63 per cent. This type of superheater is also made by Messrs Frazer and Chalmers, Erith, who have one in constant use at their works.

Sinclair's Superheater.—Another form of superheater is shown in Fig. 12, which is due to Mr. George Sinclair, of Leith. There is here a departure from the usual method of securing the tubes, which in this apparatus are flanged and bolted to the cross inlet and outlet pipes instead of being expanded into them. In such positions an expanded joint is generally considered desirable, but here the joints are removed from the action of the hot gases, and a bolted joint gives much greater facilities for removing a tube in order to examine or clean it. In Fig. 12 the apparatus is shown in conjunction with a marine dry-back boiler, as fitted by Prof. Kennedy at the Edinburgh electric lighting station. The arrangement is very compact and should prove highly economical. The hot gases from the smoke-box at the front are led to the back over the top of the boiler, passing among the superheating tubes, thence down the sides of the boiler to the centre flue underneath it. The apparatus was described in Mr. Burstall's paper read at the last meeting (October, 1895), and in the discussion Prof. Kennedy stated that further tests were then in hand.



FIGS. 9, 10, AND 11.—Schwoerer's Superheater.

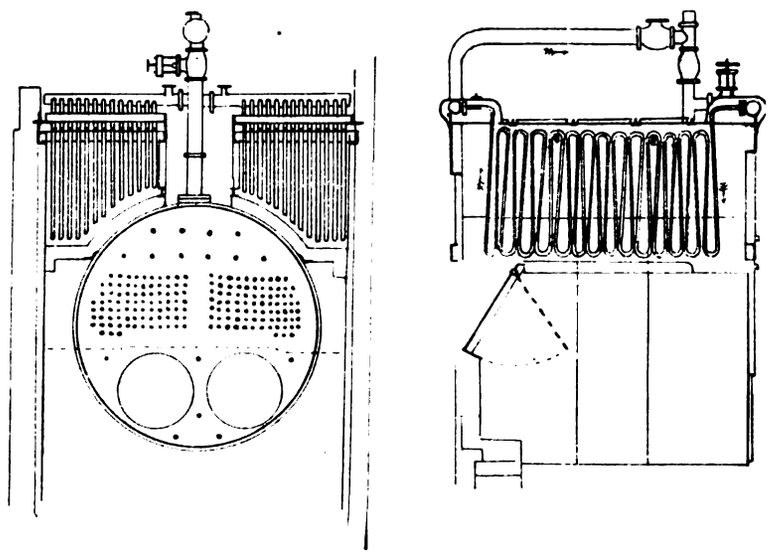


FIG. 12.—Sinclair's Superheater.

It is much to be regretted that so little has been done as yet with superheated steam at the engine. In nearly every instance the superheat appears to be gone, if not at the steam-chest, at any rate immediately on admission to the cylinder. But even under these circumstances the advantage of superheating is manifest from many of the tests given above, and it must be recognised that, although the steam may be cooled down again to the temperature corresponding with the pressure, it is still dry steam, and is a better working gas than the saturated solution of water-dust supplied by an ordinary boiler. The desirable amount of superheat has been generally considered to be the equivalent of the heat lost by initial condensation, but this does not obtain in practice. The amount of heat lost in initial condensation is generally from 20 to 25 per cent. of the total heat of the steam above boiling point. Tests with superheated steam show a saving of 20 per cent. with only 5 per cent. extra heat in the steam. This point has been brought out clearly by Mr. W. H. Booth in his paper on cylinder condensation, read to the Manchester Association of Engineers a few months ago, wherein it was shown that the amount of superheat is but little in excess of that necessary to supply the heat required for making good the latent heat which disappears as work during expansion. In conclusion, the author desires to thank the several gentlemen and firms who have kindly given him information and plans.

HIGH-VOLTAGE LAMPS, AND THEIR INFLUENCE ON CENTRAL-STATION PRACTICE.*

BY G. L. ADDENBROOKE, MEMBER.

(Continued from page 269.)

EFFECT OF USING HIGH-VOLTAGE LAMPS ON DISTRIBUTION.

On this point I do not think I can do better, as a commencement, than quote from my article in the *Electrical Review* of January 11, 1895: "How great a gain there is in distributing current at a higher voltage, and how much it simplifies the distributing problem, is not at first sight fully apparent, though everyone recognises that there are advantages. The advantages may really be said to progress as the cube of the voltage up to, say, about 200 volts. For let us suppose we have a station on all of whose circuits the lamps require 200 volts to incandesce them, instead of the usual 100 volts. In the first place, having doubled the pressure, we may extend our mains double the distance at the same current-density with the same percentage loss; but at the higher voltage the same current-density in a given sized main will give us twice the energy and light twice the number of lamps. Consequently, without increasing the sectional area of the mains, we can do four times the lighting with the same mains, or the same amount of lighting at four times the distance, with the same percentage loss. Then there is a further gain, for, since we can extend the mains four times as far from the central station with the same percentage loss, the area which can be served from a single station is 16 times greater at the higher pressure than at the lower. Presuming, however, that this argument is not pushed to its extreme limits, it is well within the mark to say that at 200 volts nine or ten times the area could be better served on the three-wire system from a single station than is now the case at 100 volts; not only is this the case with the feeders, but it extends in an even greater degree to the distributing system. At present there is no doubt that there is an inconvenient fall of voltage in the distributing mains, and the internal wiring of houses, which leads to irregular and unsatisfactory lighting, and which is under existing circumstances, whatever system is employed, exceedingly difficult to remedy. If by any means the voltage could be increased to 200 volts this would practically vanish, distributing mains might be carried three times their present distance from the feeding point, and the fall of potential in houses would be merely nominal on the present basis of wiring, instead of frequently amounting to 1-2 volts or more. By these means the number of feeding points in a given area would, of course, be much reduced. The same fittings and wiring as are now used would be applicable, and the voltage does not go beyond the Board of Trade limits." This was a general statement, made largely with a view to point out to manufacturers what a field it would open if they could produce a commercially satisfactory high-voltage lamp.

During the last 18 months manufacturers have seen the advantage of exploiting this field, with results which have already been detailed above. Consequently it is desirable to look a little more closely at the distribution problem under its new aspect, and I will therefore ask your particular attention to the figures which I now propose to lay before you. It is generally acknowledged that in the three-wire system at 110 volts it is not economical or very practical to distribute current at a radius of much more than three-quarters of a mile from the central station, except under special circumstances. The area which can therefore be economically served from such a station is about 1½ miles each way, or about 2¼ square miles. In his well-known feeder paper Mr. Crompton gave figures which he argued showed that a feeder on the three-wire system supplying 110-volt lamps could be laid and maintained, and would involve the same loss of energy, taken over the same day, as would an alternating feeder, including transformers, instruments, and switching gear, the length of the feeders in each case being 2,400 yards. These figures were strongly attacked by the alternating party, myself amongst the number; the most legitimate point of attack being that Mr. Crompton had assumed a loss of 30 per cent. at full load on the low-pressure feeder, which was considered excessive on account of the extra plant it would entail at the central station. Had Mr. Crompton put the length of his feeder at about 1,400 yards, or a little over three-quarters of a mile, and had he used a density of about 500 amperes per square inch—which is about the practical density—the loss would have been 16 per cent. for the continuous-current feeder at full load, and few alternating men would have seriously combated that on the whole the continuous-current feeder was as economical and desirable as an alternating feeder. The figures would then agree with the generally current comparison which I have mentioned above, and which I propose to use as a basis of argument in order to avoid disputes.

Now, from data I have collected, it appears that in such places as the centre of large towns there are perhaps 30,000 inhabitants per square mile, though ordinarily the population for a square mile of a town does not appear to exceed 16,000. A low-pressure station on the three-wire system with 110-volt lamps can therefore serve economically about 60,000 to 70,000 people in the centre of large towns, and about 35,000 in districts outside the centres and in provincial towns. If, therefore, we wished to light London, with its 4,000,000 population, on this basis, taking the average population at 25,000 per square mile, we should need, roughly, 70 to 80 stations to light the whole Metropolis, not counting the extreme suburbs. If, however, in the direct-supply system the voltage is double, the position is altogether altered, and a comparison between the transformer and direct-supply systems under these circumstances will lead to very different results from those so far given. Theoretically, if 220-volt lamps are used, we can extend the feeders four times as far as if 110-volt lamps are employed, and therefore the area which could be lighted from each station is 16 times as large. I do not intend to take full advantage of this facility in the calculations which I propose to lay before you, as I consider that the fall of voltage is too large in low-pressure central stations at present, and that the voltage of the lamps at different points of the distributing system is not kept as near the normal as it should be. In what I am about to say I shall therefore consider that, instead of four times, we extend our feeders a little over three times as far as before, thus securing better regulation and a smaller percentage drop in both the feeders and distributing system, together with the great saving in copper. If, then, we can extend the lighting radius three-quarters of a mile from a low-pressure direct supply station with 110-volt lamps, we can extend it, on the above basis, 2½ miles at 220 volts, which means that we can cover an area of 5 by 5, or nearly 25 square miles from one station—that is, 11 times the area we could before. Instead, therefore, of serving 60,000 people in the central districts, one central station would serve 700,000, and over a quarter of a million in the less central districts. Taking, then, the population of London as 4,000,000 without extreme suburbs, about six or seven stations would comfortably cover the whole area. Now this is a number which is directly comparable with the number of stations at present being operated by the gas companies, and to my mind it is doubtful if it would be desirable to reduce the number of stations below this figure for so large an area, even if it could be managed.

It would be interesting to go into this metropolitan lighting problem further did time permit, but it does not, and I must ask you now to turn your attention to the provinces. Take maps of Birmingham, Liverpool, Glasgow, and Manchester, and cut out a piece of tracing paper to represent 25 square miles on the same scale as the map. Lay the tracing paper over these maps and you will find that two stations, or at most three, will cover not only the whole of these great cities, but the suburbs for a couple of miles outside. For the general run of large towns one station would amply suffice, and for the smaller ones one station would, of course, permit of lighting over the whole area at a very small expense for mains. Before a technical audience like this, however, it will doubtless be more satisfactory to investigate a particular instance than to proceed further with general statements. At 220 volts pressure an ampere represents 220 watts; therefore one-third ampere represents 73·3 watts. Now at four watts per candle-power a 16-c.p. lamp takes 16 × 4 = 64 watts, and an 8-c.p. lamp 32 watts. We shall therefore be sufficiently near for the purposes of this calculation, and shall be allowing a sufficient margin, if we assume that a 16-c.p. lamp takes one-third ampere, and an 8-c.p. lamp one-sixth ampere at 220 volts.

Next consider the distributive system. There are two points needing attention: the first is, How far, and over what area, can we spread our network from the feeder points? the second is, What drop should we allow on the feeders themselves? But before going into these matters further we must settle what shall be our greatest drop from the feeder point to our furthest lamp on the network spreading from it. The variations which are permitted at present are too great, and would have to be reduced in time anyhow. I therefore do not intend to adopt the present practice as a basis, but to take as the limit an extreme fall of 2 per cent. on the distributing system from the feeder point to the furthest lamp at the tops of the houses—that is, lamps near the feeder would be 1 per cent. above their proper voltage at full load, and extreme lamps 1 per cent. below. This is, I think, as large a variation as good practice would allow, though it is less than half what is considered permissible now. Having settled this, the following data and table will enable us to see at a glance the best method of designing the mains, and their cost: (1) A bar of copper 1in. in section and one mile long weighs approximately nine tons, and its resistance is 1-22nd ohm, or 0·045. (2) Therefore a double conductor one mile long and 1in. in section weighs 18 tons, and its resistance is 1-11th ohm, or 0·090. (3) I do not think it will be necessary on the high-voltage system to have the third wire in a three-wire system more than one-fifth the

* Paper read before the Institution of Electrical Engineers, February 27.

TABLE A.—Data Relating to Feeders on Three-Wire System Supplying 220-Volt Lamps—½ Ampere per 16 c.p. and ¼ Ampere per 8-c.p. Lamp.

Current density in amperes per sq. inch.	Loss in volts per mile of double con ductor.	Percentge fall of potential at full load.	Kilowatts available per square inch section of outers = 2·2 square inches copper.	Number of lamps carried by mains one square inch section = 2·2 square inches copper.		Cost per mile of copper at 6½d. per pound.			
						Per lamp alight at once.		Per lamp installed = twice lamps alight	
				16-c.p.	8-c.p.	16-c.p.	8-c.p.	16-c.p.	8 c.p.
		Per cent.				s. d.	s. d.	s. d.	s. d.
1,000	90	17	440	6,000	12,000	4 0	2 0	2 0	1 0
500	45	9·3	220	3,000	6,000	8 0	4 0	4 0	2 0
400	36	7·6	176	2,400	4,800	10 0	5 0	5 0	2 6
300	27	5·8	132	1,800	3,600	13 5	6 8	6 8	3 4
250	22·5	4·86	110	1,500	3 000	16 0	8 0	8 0	4 0
200	18	3·85	88	1,200	2,400	20 0	10 0	10 0	5 0

section of the other two, except, perhaps, in the distributing system. In fact, I understand Mr. Crompton considers the third wire could be done away with altogether as soon as the feeder gets a good load joined up to it, so that only the distributing system would need the third wire, these wires being joined together at the distributing point.

Consequently, the weight of a set of mains on the three-wire system—the two outers 1in. section, and the inner 1·5in.—would be 20 tons per mile; and the cost for copper at 6½d. per pound would be £1,210 for the copper in the mile of mains. Now at 1,000 amperes per square inch a main this size would carry current for 6,000 16-c.p. lamps, if perfectly balanced on the above basis, and the fall of pressure would be 90 volts in the mile, or 17 per cent. Such a fall of potential as 17 per cent. in the mile is excessive, and therefore we must arrange to work at a smaller current density. To enable the best current density to be judged, I have arranged the accompanying table (see Table A) which enables us to see the reduction in fall of potential which we get by reducing the current for a given section, and also the cost for copper which will be incurred for such density per mile run.

Now, it is not unusual in some low-pressure central stations to have falls of even more than 16 per cent. at full load on the longest feeder; but this is an undesirably great fall, save on exceptional occasions, such as Christmas week, or during a fog in winter, and I think, with the immense reduction in copper cost which the use of high-voltage lamps gives, it is desirable to work with smaller falls. Suppose we accept 250 amperes per square inch as a basis, it will be seen that mains on the three-wire system will cost us 16s. per 16-c.p. lamp alight at once, and 8s. per 8-c.p. lamp per mile, and the drop of potential will nearly be 5 per cent. Now, if we assume that current is supplied 2½ miles from the station as an extreme, as we did before, our longest feeders will be about this length, the drop at full load on the feeder will be about 12 per cent., and the cost of copper 40s. per 16-c.p. lamp, and 20s. per 8-c.p. lamp alight at once for the longest feeder. If we take the network as proceeding from the feeder points at the same current density—namely, 250 amperes per square inch—and if we agree that it shall extend rather over a quarter of a mile from the feeder point, to allow for irregularities, so that each feeder will feed a network covering half a mile square, it will be noted that the drop, including extra lengths of main for going round angles and into the houses, will be about 1½ per cent., and the extreme cost of copper per lamp alight at one time in the network will hardly be more than 4s. per 16-c.p. lamp, and 2s. for an 8-c.p. lamp, while the mean cost will be about three-fourths of this, and the mean drop of potential only 1 per cent.—and even this can readily be reduced by a little judicious adjustment. We therefore see that for feeders extending about 2½ miles, and a network extending a quarter of a mile further from the feeding point—that is, 2¾ miles altogether—the extreme cost for copper per 16-c.p. lamp lighted at once will be about 44s., and for an 8-c.p. lamp under 22s. This represents extreme lengths. The average length of feeders to cover the above area would hardly be more than 1¾ miles, or three-quarters of the above maxima, and the cost of the copper, on the average, in the distributing system will be reduced in like proportion. We shall therefore be correct in taking three-fourths of the above sums as the average cost of copper per lamp lighted at once from station to lamp, including both feeder and network, in a station covering a town area of equal density 25 square miles in area. This is, approximately, per 16-c.p. lamp, 33s.; per 8-c.p. lamp, 16s. 6d. Further, from practice and the tables in *Lightning*, we know that there are usually at least twice as many lamps installed as are required alight at once; therefore we may put the capital cost of mains for copper only at about, per lamp installed, cost of copper, 16-c.p., 16s. 6d.; 8-c.p., 8s. 3d. Now, it is fair to take 6 per cent. per annum as the sum to allow for interest and depreciation on the copper in the mains—say, 3½ per cent. for interest and 2½ per cent. for depreciation. At this rate, on the above capital cost, the annual cost for interest and upkeep comes out at under 1s. per 16-c.p. lamp and 6d. per 8-c.p. lamp installed. Further, on looking through the tables of consumption of current it will be found that 18 units per 8-c.p. lamp installed is a fair all-round average—at least, it is the average from *Lightning* for London and most of the provincial stations. At this rate, therefore, it will be seen that the upkeep and interest on capital for the copper in the distributing system comes to 0·33d., or one-third of a penny per unit of current sold; or, supposing the sum actually received for current is 6d. per unit, the cost for interest and upkeep on the copper in the distributing system represents less than 6 per cent. of the cost of current. Out of this cost it will be noticed that about three-fourths of the copper is in the feeders, and one-fourth in the distributing system. I may say that Mr. Crompton objects to the method of taking the consumption per 8-c.p. lamp installed as a basis of comparison, and I quite agree that it is rough and unscientific. Mr. Crompton suggests the relation between the annual output in B.T. units and the output which would be registered if the maximum load were continued day and night throughout the year. In this case he tells me the actual output would vary from the equivalent of full load for 700 hours in some country towns to 1,000 in parts of London, 1,300 in Kensington, and a much higher figure for the Pall Mall and St. James's Company; 1,300 hours corresponds to a load-factor of 15 per cent., though it will readily be seen that it is a figure of more comprehensive nature, and not exactly similar. I leave this question here, however, as, though very interesting, to discuss it further now would be out of place in this paper.

In order to complete the comparison made above, the cost of insulating and of laying the cables should, of course, be taken into consideration. In order to set this point at rest, Mr. T. O. Callender has kindly prepared for me data deduced from their experience in supplying and laying cables, which, as the result of a large amount of practice, are beyond cavil, and which show the average cost of cables laid as compared with the cost of the copper in them. These particulars are given in Table B:

Table B.—Total Cost of Insulated Cables laid complete, as compared with the Cost of the Copper contained.

Character of cables (separate).	Armoured, laid direct.	Plain, laid in solid bitumen.	Armoured, laid direct.	Plain, laid in solid bitumen.
Area of cable { Outer	Sq. inch. 0·50	Sq. inch. 0·50	Sq. inch. 1·00	Sq. inch. 1·00
Area of cable { Middle ..	0·25	0·25	0·50	0·50
Area of cable { Outer	0·50	0·50	1·00	1·00
Cost of cable laid complete, exclusive of excavation	19s. per yd £1,650 per mile.	25s. per yd. £2,200 per mile.	33s. per yd. £2,900 per mile.	42s. per yd. £3,700 per mile.
Excavation, cheap streets and lanes...	s. d. 1 3	s. d. 1 3	s. d. 1 3	s. d. 1 3
Excavation per yard, average run of trench in towns under macadam or pavement	2 0	2 0	2 0	2 0
Ratio of cost of copper (at 7d. per lb.) to cost of complete cable laid, as 1.....	2·5	3·1	2·2	2·3

Under asphalte or wood the cost of excavation will run up to as much as 15s. per yard run, but this item will practically be the same whatever system is used. Moreover, as only a few of the main streets in large towns are so paved, this item is not one which need concern us particularly in a general comparison, but must be dealt with in accordance with local circumstances in each case. It will be noticed that in the above table the middle wire is half the section of the outers; in practice it would not be necessary to have this more than one-fifth for the

Digitized by Google

feeders, and in some cases it might be omitted entirely. The actual cost of feeders should therefore come out about 10 per cent. under the prices given, though I have thought better to leave the table as it was, preserving Mr. Callender's own figures. At these rates, for a two-mile feeder of armoured cable, working at a current density of 250 amperes per square inch, the cost, laid complete, would be about £55 per kilowatt for the maximum output; the fall of pressure being about 10 per cent. I think, therefore, that the whole distributing system—consisting of feeders, branches, local services, service boxes, and every other item, also providing for a fair proportion of the cables being laid under asphalte or wood, from such a station as I have described above, with a service extending 2½ miles in all directions—could be laid complete for £60 per kilowatt. This is a very moderate figure as compared with the sums now spent. If we assume that 8 per cent. is required to meet interest, upkeep, and depreciation on this outlay, and if we take the output of the station at 800 kilowatt-hours maximum load on the basis suggested by Mr. Crompton, it is evident that interest and upkeep on the distributing system would cost about 1½d. per unit of current sold for the whole distributing system; so that a charge of 1½d. per unit would cover all costs outside the station itself. From what we know of the cost of generating electric energy, it will, I think, thus be clear that, even in places where coal was expensive, a very good profit would be made by selling current at 4d. per unit for lighting and 2½d. for power purposes. In making this calculation I have assumed the same density of population over the whole area; but it is evident that this would very seldom be the case, as in nearly all towns at two miles from the centre the density of population is greatly reduced, which would mean a smaller proportion of long feeders, and consequently a less average cost per kilowatt output than I have taken.

I do not wish it to be assumed from what I have said above that the capital cost of a direct-supply station at 220 volts, with feeders and distributing system extending 2½ miles, as described above, would be as low as that for an alternating station at 2,000 volts, with transformers and 220-volt lamps, to cover the same area. It would not. Comparing feeders, I think, with the present prices of mains, and using the same class of insulation in each case, as is frequently done now—that is, not using expensive rubber cables for the high tension—the two systems are equal in cost for feeders 1½ miles long. As the distributing system will extend a quarter of a mile further beyond the end of each feeder, a direct-supply station on exactly the same lines is as cheap in capital cost for an area having a base of at least 3½ miles, and covering 10 square miles. Further, as something must be allowed to the direct-supply system on account of lower depreciation and greater safety and freedom from restrictions and ability to supply motors more easily, another quarter of a mile may easily be allowed on the feeders of the direct-supply station on this account, so that the systems compare together when the base of the area served is four miles, and the area itself 16 square miles, even if no accumulators are used. Although this is not as large as the area I have taken as a basis, what it means can be estimated from what has been said above as to the actual areas covered by large towns. I am, of course, assuming that 220-volt lamps are used on the transformer station as well as the direct. If we assume that the transformer station employs 100-volt lamps, of course the comparison would be much more decidedly in favour of the direct supply at 220 volts. There is no need, however, to go very minutely into these figures, because, though thoroughly practical, they do not represent what it is clear will be central-station practice in the future, as I do not think it probable that any direct-supply station in the future will be operated without accumulators.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS, Mar. 12.

DR. HOPKINSON (President) in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Foreign Member.—Fritz Nial Wolff, Aarhus, Jutland, Denmark.

Associates.—Samuel Ernest Andrew, King's-road Central Station, St. Pancras, N.W.; Wellesley Curran Clinton, University College, Gower-street, London; A. H. Lidderdale, White Hill, Berkhampstead; Harold John Lintott, Parkfield. Horsham; Marshall Osborne, 81, Manor-road, Brockley, S.E.; Robert Cornelius Quin, Kensington House, Hamilton-road, Brighton; Henry John Rogers, the Watford Engineering Works, Watford.

Students.—Alfred H. J. Graham, 27, Gower-street, W.C.; Archibald Victor Mason, Carbery Lodge, Ascot; William Edmund Miller, 33, Clarence-street, Loughborough; John Robert Milnes, 67c, Upper Tulse-hill, London, S.W.; Sidney A. Nash, 29, Cambridge-street, Loughborough: H. Ralph C. Partridge, Hockam, Thetford, Norfolk; John M. Robb, 48, Marlborough-Hill, London, N.W.; Reuben M. Sayers, 7, St. Peter's-square, W.; Frank S. Shaw, 32, Clarence-street, Loughborough, Leicestershire; Herbert Turnbull, 60, Toothill-road, Loughborough; Robert N. Tweedy, Redruth Cornwall; Charles Percy Walker, Shaw-lane, Headingley, Leeds; Leonard Wilson, 33 Clarence-street, Loughborough; Claude P. Wooler, Danemoor, Darlington.

The discussion on Mr. Addenbrooke's paper on "High Voltage Lamps" was then resumed.

The President said it was absolutely necessary that they should conclude the discussion on the paper that evening, as Mr. St. Clare's paper must come on at the next meeting. He suggested that those gentlemen who had any remarks to make should be as brief as they reasonably could.

Mr. Swan said the paper raised the question whether the time had not arrived when electrical engineers might arrange their plans for general electric supply on the assumption that incandescent lamps for a double voltage to what are now in vogue would be forthcoming on demand, and whether those lamps would be as cheap and as good as those of lower voltages. He passed over the question whether there was a possibility of a different kind of lamp of Crooke's tube or Tesla type superseding the lamp now known, but, at least, it might be said that the symptoms of its near approach were not sufficiently marked to make it necessary for the electrical engineer to take the possibility into immediate account. The question of the greatest moment was whether incandescent lamps of low candle-power, and requiring a voltage of 200 or 250 volts, could be made to compete in point of efficiency and cost with lamps of the lower voltage now in use. The demand for such lamps was a comparatively new demand, but fast increasing, and the pressure was sufficiently strong to compel the manufacturers to meet the demand by a supply at a moderate cost of a lamp which should be suitable for the double voltage, and which should have a fairly long life and a fair efficiency. From his own experiments he knew that it was possible not only to fulfil the very moderate requirements stated by Mr. Addenbrooke, but to go considerably beyond that, and as time went on the result would be both increased efficiency and diminished cost. A lamp of 200 or 250 volts of 8 c.p. was a more fragile thing than the 100-volt lamp of the same candle-power, such as at present made. Looking at the question from the point of view of the electrical engineer, instead of the lamp manufacturer, it was fairly clear that this practice would have a sufficient and perhaps more than additional recompense in the additional facilities that came from a wider and more economical distribution of current from supply stations, which was a very important advantage, and fully justified a very considerable sacrifice in obtaining it. In new work he saw no other objections to high voltage lamps than those Mr. Addenbrooke had named, but great care would have to be exercised in existing installations. Mr. Addenbrooke had given two years for the thorough elaboration of the higher voltage system, but in his opinion that was a very liberal allowance; so far as the lamp manufacturer was concerned, he did not require it. To go from the question of high voltage to that of efficiency, the real difficulty here was connected with the employment of the lamp on a higher voltage. The fluctuations of pressure to which lamps were subjected were commonly too great to give the high-efficiency lamp a fair chance. At 2½ watts per candle the filament was heated to a very high temperature, and a rise of voltage beyond that was very trying to the life of a lamp. They all knew that even the best lamps of that character would not bear very long any extra pressure producing a super-high efficiency and a super-high temperature. In nearly all the public supply companies the normal voltage was often exceeded by more than 5 per cent., sometimes 10 per cent. When such extra pressure was brought, the result was disaster, and the lamps gave way. But given a voltage that never rose more than 1 or 2 per cent. above the normal, there was no difficulty in realising that economy of current which was obtainable by the use of a 2½-watt lamp. He hoped in the near future it might be practicable to make a much more general use of lamps of high efficiency than under existing circumstances would be convenient or economical.

Mr. Stearn quite agreed with Mr. Addenbrooke's view that economy in lighting could be more easily reached by high pressure and low temperature than by high temperature and low pressure. So far as duration was concerned there was not much difficulty; where the pressure was regular, satisfactory results could be obtained. The difficulties in the way of the construction of high voltage lamps were mechanical ones, and he proceeded to explain how the filament could be fixed in a lamp so as to get a single filament lamp instead of a double as at present.

Mr. Snell said there had been very little trouble with the higher voltage lamps at St. Pancras, and **Mr. Robertson** remarked there was no difficulty in the new lamps from the makers' point of view.

Mr. Geipel thought no one would deny that lower voltage lamps could be run at a better efficiency than the 200-volt lamps. He would like to see Mr. Stearn's improved filament applied to the 8 c.p. 100-volt lamp.

Mr. Epstein, Mr. Campbell Swinton, and **Mr. Patchell** continued the discussion, and were followed by **Mr. Handcock,** who thought that at 100 volts the limit had been reached. He agreed with Mr. Swan as to the absolute necessity of a steady voltage, and thought the supply company should test and supply the lamps.

A communication from **Mr. Baynes** was read, in which it was suggested that high efficiency 100-c.p. lamps might be used two in series on the higher voltage, say, in shops, and the **Chairman** remarked that in Manchester they had taken all five wires into the Town Hall, and used as many as four lamps in series.

Mr. Addenbrooke then replied, acknowledging the assistance given him by Mr. Crompton and others in preparing his paper.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

PARALLEL RUNNING.

The question of parallel working of alternators has exercised the minds of engineers and electricians for several years. The changes in the theories of the subject have been many, and in few cases have really practical results been obtained from the theoretical considerations. The latest information on the subject is the paper read by Mr. Robert Hammond, at Manchester, before the Northern Society of Electrical Engineers. This paper, which we have been obliged to condense somewhat, must be considered as a distinctly practical one, as although the arrangement of the results has a tinge of an old theory in it, the facts are obtained from the engineers in charge of the machinery running in parallel. Returning for a moment to this old theory, that alternators can be classed according as to whether there is iron in the armature or not, the fallacious conclusion was that these factors determined whether or no there was self-induction in the armature. This, now, has been disproved again and again, as explained on page 94 of our issue of July 22, 1892. The self-induction of coils surrounded, as they must be, with iron can be just as high as those having iron cores. Answers obtained by Mr. Hammond, as at present divided, practically afford another proof of this fact. The whole question of the successful paralleling of alternate-current dynamos can preferably be divided as follows: firstly, the consideration of the curve of turning moments of the prime mover at different periods of the revolution; and, secondly, the corrective stresses set up by the alternator armature when the variation of the speed causes it to lead or lag behind the position of synchronism by a definite amount.

These are the fundamental considerations, and they can both be ascertained exactly if the design of engine and alternator are known. The even turning moment is of the highest importance, as evidenced by the failure of the attempt to use gas-engines, and also of some slow-speed steam-engines, for parallel working. Hence the prime movers may be classed as follows as regards their relative advantages for parallel working: turbines, three-crank engines with both a high and low pressure cylinder to each crank, similar two-crank engines, high-speed two-crank engines with high and low pressure pistons working on to separate cranks, and, finally, slow-speed engines of the same construction, and tandem engines. The chief fault with all but the first class of engine is the fact that the distribution of the load between the high-pressure and low-pressure cylinders varies so much with the load, and hence two differently loaded engines have widely different crank-effort diagrams. Then, coming to the alternators, the one most suitable for parallel running is that one in which a small deviation from the position of synchronism does not cause too violent corrective forces, but as the deviation increases these forces must increase. This effect is produced by self-induction, without which the running of the alternators would be as rigid as spur gearing, and at the expense of large synchronising currents. The author of the above paper concludes that

Digitized by Google

flywheels are a great assistance to parallel work because of their influence on regular speed. On the contrary, although as a general rule the flywheel may be an advantage in certain cases, it is a distinct disadvantage, as proved at Derby. In fact, we would say that in most cases of the parallel working from slow-speed engines the parallel working is ensured by the excellent design of the alternator, in spite of the disadvantage of the engine. In conclusion, we would call attention to the following facts, which apparently some engineers do not know. When the average alternator is working loaded, a short-circuit in the mains will cause the engine to increase in speed. In this respect a short-circuit on an alternator is not so dangerous as one on a direct-current dynamo, as the short-circuit reduces the load. Also, that with a usual amount of self-induction in the armature, a temporary short-circuit will not harm the machine. This point, as a radical essential of alternator design, is carefully explained by Mr. E. Kolben in our issue of January 31.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRICITY A MODE OF MOTION.—THE RONTGEN RAYS. WHAT ARE THEY?

SIR,—It will be remembered that immediately on the receipt of the news of Prof. Röntgen's discovery, the writer claimed that the phenomena there described formed an additional proof that the theory of "What Electricity is" which he had formulated in the columns of the *Electrical Engineer* three years ago was correct. In his opinion the later information on the subject confirms the view he then took, though naturally modifying that view in points of detail.

Consider for a moment how the rays are produced and what their properties are, and their identity with the waves the writer believes to emanate from electrostatically-charged bodies will be apparent. Perhaps a point had better be mentioned here in connection with the matter of the identity of the rays. The writer's first view was that the Röntgen rays were merely electromagnetic waves, whose position in the physical scale he placed beyond the ultra-violet rays of the spectrum, their wave lengths being shorter and their rate of propagation faster than those of the ultra-violet waves. Subsequent study of the experiments that have been made on the Röntgen rays has led him to adopt the view that these rays are waves such as would emanate from an electrostatically-charged body, electrostatic waves, if the term be allowed, or simply electric waves. But he has also been led by a consideration of these experiments, and of those of Hertz and others, to doubt if there is really any difference between an electric wave such as would emanate from an electrostatically-charged body and the electromagnetic waves that we know emanate from a conductor in which electric currents are passing. Such differences as there are between the two forms of waves appear to the writer to be merely of degree, somewhat similar to the differences between the waves present in different parts of the spectrum, these differences being due principally to the difference in the E.M.F.'s ruling in the two cases.

The conditions necessary for the generation of the Röntgen rays appear to be the presence of a very high E.M.F., capable of giving a spark of not less than 2in. in air, and the opposition to this E.M.F. of an enormous resistance. Apparently an E.M.F. of not less than 100,000 volts is necessary where the Röntgen rays are formed, and a very much higher voltage unless a high rate of alternation or oscillation is also present. Apparently, the rays may be formed either on the *outside* of the glass of a vacuum tube that has been exhausted to a very high vacuum, something like $\frac{1}{1000000}$ of an atmosphere, or simply in the path of the brush discharge of an electrostatic induction machine having a sufficiently high E.M.F. The properties of the rays are: (1) The ability to pass through nearly all substances except metals, just as light rays pass through clear glass, and to pass through even some metals if only a thin plate of the metal is present; (2) the ability after passing through various substances that are insulators to electric currents, using the term in its popular sense, of performing the work done by the highly refrangible rays of the spectrum—that is to say, the ability to produce certain chemical changes in certain substances similar to those produced in the same substances by the actinic rays; (3) the ability to be converted actually into light rays when caused to impinge upon certain substances, such as platino-cyanide of barium, and this after passing through other bodies which are impervious to light; (4) the property of denoting the presence of metals in particular, and of other substances to a lesser degree, by the stoppage of the passage of the rays, and of the subsequent transformations, where these bodies lie in the path of the rays; (5) the ability to discharge electrified bodies, notwithstanding the fact that these bodies are carefully insulated.

But the ability to pass through all substances is a property that we well know to be common to all electrical discharges, no matter what form they take, providing the E.M.F. present is sufficiently high, and it is also a property now well known to exist with comparatively low E.M.F.'s, provided oscillations of very high frequency are present, as witness the vagaries of lightning and the startling effects obtained by Tesla, Elihu Thomson, Campbell Swinton, and others. It is a property with which every experimenter with high-tension apparatus is familiar, and is especially common to those apparatus in which alternate or oscillatory currents are present. The ability to stop or attract electrical discharges is also a property common to all electrical discharges more or less, but particularly to those in which high tensions are employed, as witness again the vagaries of lightning discharges and the experience of everyone who has handled an induction coil. The meaning of the apparent stoppage of the rays is not that metals and other bodies oppose their passage, but that they absorb the rays, screening objects beyond, just as a ring of iron screens a compass needle, and just as a metallic body screens objects behind it from heat rays emanating from a source in front. So, too, as the screening effect of the ring of iron for magnetism, and of the metallic body for heat, is only partially depending upon the mass of the screening body, the pressure ruling, and the specific capacity of the screening body for the particular form of energy it is warding off, so is the screening effect of metallic and other bodies from the Röntgen rays dependent upon their capacity to absorb these rays, their mass and form, and the pressure or force with which the rays impinge on them.

In (2) and (3) we have a similar conversion to that which takes place when an electric current generates heat, but owing to the very high E.M.F., the very high resistance, and the small space over which the action takes place, part of the electric waves pass at once into light waves, and proceed to perform the work that light waves do. The electric waves are retarded, and necessarily their wave lengths are shortened and their rates of vibration increased, just as in the case of an electric current passing in a conductor, but the conditions being different the results are naturally different. We have exactly the same thing happening in the vacuum tube, but in another way, and to a smaller degree. The discharge of insulated electrified bodies is evidently due also to the presence of the superior E.M.F. The waves, acting under the influence of the high pressure ruling, sweep through the conductor and its insulating envelope, the original charge joining with high-pressure stream of waves, and leaving the conductor discharged. The heat generated in the vacuum tubes is probably due to the mechanical bombardment of the molecules of the electrodes, which we know takes place

Digitized by Google

under the high pressure ruling, but some will probably be due to direct conversion of the electric waves.

To sum up then. The writer submits that the Röntgen rays are electrical waves forced into space under very high tension, and that their action upon sensitive photographic plates is due to their conversion into light waves by the films themselves, upon which the action takes place; this conversion being due to the resistance offered by the films to the passage of the waves, just as the resistance of an electric conductor causes the conversion of a current passing through it into heat. Their ability to denote the presence of metals and other bodies is due to the capacity of those bodies, under the conditions ruling, for storing the electrical waves, and so screening those portions of the sensitive film that lie beyond.—Yours, etc., SYDNEY F. WALKER.

PARALLELING OF ALTERNATORS.*

BY ROBERT HAMMOND, MEMBER.

Those of my audience to-night who had occasion to attend the Board of Trade enquiry in 1889, presided over by Major Marindin, and held to consider the applications for provisional orders by rival companies in the Metropolis, will remember that the opponents of the high-tension alternating system made much of the fact that it was impossible to run alternators in parallel, or, rather, that up to that time no practical method of doing so had been worked out. It is interesting in these days, when parallel running of alternators is almost universal, to peruse the expert evidence on the subject that was given during that enquiry. I do not intend to trouble you with that evidence in detail this evening, but I may now, however, summarise it by stating that while Dr. John Hopkinson, Mr. Alexander Siemens, and Mr. J. E. H. Gordon all held distinct opinions that such a plan of working was possible, all confessed that they were unaware of any works where it obtained. Lord Kelvin and Dr. J. A. Fleming gave evidence to the effect that there was no intention of working under these conditions at Deptford, while Mr. R. E. Crompton and Mr. James Swinburne, called in opposition to the alternating system, and aided by an expert from America, emphasised the fact that such a method of working had never been carried out in practice anywhere. On the other hand, it was taken for granted throughout that enquiry that it was absolutely necessary in an electricity supply works to run the "generators" in parallel in order to permit of changing over without the slightest flicker in the event of (*a*) a hot bearing, (*b*) a falling or rising load, thus making it possible to work each set of plant at its highest efficiency.

With regard to the proviso as to the necessity of avoiding the slightest flicker, the members of this society, imbued with the idea that an electricity works manager is unworthy of his position who deliberately plans a "blink or two" each evening, will, I am sure, recall with amusement, as well as astonishment, the calm way in which in the early eighties in the pioneer works the circuits were regularly each night at a certain hour completely cut out, pending the transfer of the work to the "light-load plant." I think it may be claimed that modern electricity works managers place absolute continuity of service—steady as a rock—above all other considerations, and I am sure that those among my audience who hold those positions will appreciate the weight of the objection raised to the alternating system as to its non-paralleling possibilities. If the doubts of the opposition had proved correct, and alternators could not be paralleled, it would be necessary, in order to avoid the slightest flicker, to work on the following lines: (1) the number of circuits and alternators to be identical; (2) each circuit fed by a separate alternator; (3) the maximum demand on each circuit never to exceed the maximum capacity of its corresponding alternator. Under this arrangement, each set of plant would be working most inefficiently at the time of low load, and the balancing of the circuits would be a constant source of worry to the engineer in charge of the ouside work. Altogether, it will, I think, be admitted that the mere statement of such an alternative would be sufficient to condemn the alternating system entirely, for it is evident that the works plant can only run at its highest efficiency by joining up the various circuits to one 'bus bar, or possibly to two, and throwing on one set of plant after the other as the load rises, reversing the operation as the load falls off.

To take an illustration from actual works. Last year the Madrid electricity works were equipped with nine 100-kilowatt sets, designed to give normally a current of 50 amperes at a pressure of 2,000 volts, each plant, however, capable on an emergency at the time of top load of giving 60 or even 65 amperes. There are nine circuits running from the works, and while inspecting the works there in October last I found that at one period of the run the demand was almost evenly distributed over the nine circuits thus:

Circuit.	Amperes.
No. 1	40
,, 2	33
,, 3	36
,, 4	38
,, 5	34
,, 6	35
,, 7	38
,, 8	30
,, 9	32
Total	316 amperes.

By feeding this from one 'bus bar six sets of plant were capable of coping with the load, while a seventh was running up for parallelling. The whole of the six sets were running at their point of maximum efficiency; whereas, on the one-circuit one-alternator plan, the nine plants would have all been running inefficiently. At the time of top load the advantages of parallel running became even more marked, for the output then took the form of—

Circuit.	Amperes.	
No. 1.	73	The normal capacity of each alternator being 50 amperes ×2,000 volts.
,, 2.	54	
,, 3.	59	
,, 4.	55	
,, 5.	64	
,, 6.	63	
,, 7.	68	
,, 8.	56	
,, 9.	58	
Total	550	

Here the total, through straining the capacity of the works to the utmost, was coped with by the nine alternators, but on the one-main one-alternator plan the extra demand on circuits Nos. 1 and 7 would have proved too much for the corresponding alternators. The dictum therefore laid down at the 1889 enquiry was, I think you will all agree, a correct one, and happily the confidence of the supporters of the alternating systems in the possibility of perfect paralleling has proved to have been amply justified.

I have alluded to the expert evidence that was given at the enquiry, wherein the experts one and all agreed that parallel running had not been carried out, and I think it is an evidence of the sturdy spirit animating electrical engineers that before

*Abstract of paper read before the Northern Society of Electrical Engineers.

Digitized by Google

the enquiry closed, and in the short space of 10 days, Mr. W. M. Mordey announced his intention to read a paper on the subject before an early meeting of the Institution of Electrical Engineers, describing a series of satisfactory paralleling experiments which he had personally carried out with the Mordey alternators. Indeed, before the enquiry closed a surprise was afforded when, on almost the last day, Prof. George Forbes gave evidence of having the night previously witnessed the perfect paralleling of the Lowrie-Parker alternators laid down by me some months previously at the West Brompton works of the House-to-House Electric Light Supply Company.

Though parallel running had been described by Wilde in the *Philosophical Magazine* of January, 1869, and had been demonstrated experimentally by Dr. Hopkinson and Prof. Grylls Adams on the De Meriten's machines at the South Foreland in 1884, the running of the Lowrie-Parker alternators in regular work on the load at West Brompton was the pioneer of the present parallel running in our alternating-current high-tension electricity supply works. It may be of interest therefore to describe the method of paralleling that was then adopted which was thought out and applied by my then assistants, Mr. William Lowrie and Mr. Chas. Jas. Hall, and I give the following extract from a pamphlet descriptive of the works published in January, 1889: "For synchronising, previous to connecting two dynamos in parallel, an incandescent or glow lamp is provided beside the unit switch blocks; this is first switched in a circuit between and comprising a coil of each armature of the two alternating-current generating dynamo machines. When it is desired to couple together the said machines for supplying the circuits in parallel, the two machines are run as nearly as possible at the same speed, and when their phases synchronise (as indicated by the lamp) they are switched together by the plugging of the corresponding switch terminal base." Here it will be seen there is described exactly the method in vogue at almost all modern works. It is, however, not claimed that at the West Brompton works practical paralleling was carried out for the first time. That distinction, I think, belongs to the firm of Ganz and Co., whose representative—Mr. Otto T. Blathy—ran the alternators at the Rome works in parallel in May, 1888. The plant consisted of alternators driven independently each of its own engine.

Number.	Kilowatts.	Volts.	Amperes.	Revolutions.	Engine.
2	90	2,000	45	250	Sulzer.
2	320	2,000	160	125	Van der Kerchoven

On the evidence of Mr. Zipernowski, the adoption of this method of working was followed by the electricity works at Turin, Leghorn, Frankfort-on-Main, and Marienbad. In all these cases there was iron in the armature coils, causing, of course, a large amount of self-induction; and in Mr. Mordey's paper on "Alternate-Current Working," read before the Institution of Electrical Engineers on May 23, 1889, the author summed up the prevalent opinion at that period as follows: "alternators may be successfully run in parallel if they have a good deal of self-induction, and to secure this it is better that they should have iron-cored armatures"; whilst he announced himself prepared to to submit the view, "that a perfect alternator for any and every purpose should have no resistance and no self-induction." In order to support this bold contention, Mr. Mordey described a series of perfect paralleling trial runs of the Mordey alternator, but his deduction therefrom, in reference to the importance of the absence of self-induction, was strenuously combated by the highest authorities, and the controversy, transferred to the technical papers, raged for some months principally through the difficulty of suppressing Mr. Swinburne when once in circuit. Those interested in the mathematics of the subject would find it a plesant task, as I have recently found it, to re-read Mr. Mordey's paper and the controversy which it provoked.

My object this evening, however, is not to revive the sleeping Mordey *v.* Swinburne controversy, but to set before you the present position of parallel running in works in the United Kingdom using the alternating high-tension system. I cannot help feeling some amount of personal satisfaction that they are now so numerous. When Mr. Ferranti made a practical success of the system at the Grosvenor Gallery by running the transformers in parallel instead of in series I at once applied the system to our works at Eastbourne, where it proved so successful that I designed all my new work on the same basis. To establish the system many prejudices had to be overcome, and, as is usually the fate with pioneers, much personal monetary loss had to be encountered, but happily to-day the system is acknowledged everywhere, except in Manchester, to be the only one suitable for scattered areas, and the record total cost of production, 2·05d., is held by a company working on the alternating system—*i.e.*, that at Leeds—while the record works cost for works not having the assistance of public lighting is held by the same company—viz., 1·46d. The relative amounts invested in the various systems in the United Kingdom to-day are: in the Metropolis, low tension, £1,395,297; high-tension continuous, £129,850; high-tension alternating, £2,739,556 — total, £4,264,703. Outside the Metropolis, low tension, £1,647,776; high-tension continuous, £117,420; high-tension alternating, £1,885,340 — total, £3,650,536.

In order to enable me to lay before this society data as to the present practice with regard to paralleling, I have asked each of these works managers to kindly supply me with the following data. The queries were addressed to the following works managers, which I divide into: (*a*) Those who have kindly sent the data asked; (*b*) those who have replied that they do not run in parallel; (*c*) those who decline to give or refuse to allow data to be published under their names; (*d*) those who have not replied at all:

(*a*) Ayr, Altrincham, Bath, Blackpool, Bolton, Bournemouth, Bristol, Burton, Cardiff, Cheltenham, Coatbridge, Chelmsford, Derby, Deptford, Dover, Dublin, Eastbourne, Exeter, Halifax, Hanley, Hampstead, Huddersfield, Larne, Leeds, Portsmouth, Prescot, Southport, Kingston-on-Thames, Woking, Newport (Mon.), Woolwich, Salford, Tunbridge Wells, Worcester, Sheffield, Yarmouth.

(*b*) Bray, Cambridge, Newcastle and District, Scarborough, Taunton, Carlow, Coventry (not yet), Blackburn (not yet), Keswick, Reading (not yet), Sunderland (not yet).

(*c*) City of London, Newcastle-on-Tyne, West Brompton.

(*d*) Bedford, Ealing, Edinburgh, Lynmouth, Metropolitan Company.

I regret to be without data from the two companies having the largest alternating works in the kingdom. With regard to the Metropolitan Company, I believe I am right in stating that they do not run in parallel; and in reference to the City Company, the directors do not consider it advisable at the present stage to publish any data as to the working of their plant. Bearing in mind the distinction set up by Mr. Mordey, it is found that in these works, out of a total output of 11,401 kilowatts, the machines without iron in the armatures are in output just double of those with iron in the armatures. This result is largely contributed to by the 4,500 kilowatts in the Deptford works. The proportion of direct-driven and rope-driven plants is as follows: I. With iron in armature, direct driven, 1,381 kilowatts; rope driven, 3,820 kilowatts. II. Without iron in armature, direct driven, 7,368 kilowatts; rope driven, 3,820 kilowatts. The tendency, however, is strongly in favour of direct-driven slow-speed plants, and in considering the data that has been supplied special interest attaches to that from works where this type of plant has been recently introduced. [The answers to questions 1 to 7 are contained in the table at the end of the paper.—Ed. *E. E.*]

Question 8.—What would be the result if an idle alternator were accidentally connected to the active omnibus bar while the others were working and connected thereto?

With Iron in Armature.

Leeds.—(L. and L. and E. C. C.) This was done accidentally, and the dynamo was left in circuit for about one minute. The idle dynamo ammeter registered about twice its full output, but the dynamo was not damaged at all. It took its load shortly afterwards, and nothing was noticed to lead me to suppose that the machine was hurt in any way.

Newport.—(L. and L.) Have actually connected by mistake and switched off again without damage being done, although big load was put on the other machine at the moment. Fuses did not blow.

Woking.—(Mather and Platt.) Pyrotechnic display. The idle machine would, of course, be nearly a dead short between the bars.

Without Iron in Armature.

Coatbridge.—(Mordey.) The idle alternator would be speedily burned out if its main fuse failed to act.

Deptford.—(Ferranti). General and serious trouble all round. Lights out and probably damage to the running machines as well as to the standing one.

It would appear from the replies that the only places where this has occurred are Leeds and Newport, and in both these cases without ill effect. In all the other cases the answers state that the fuses would blow. From the tenor of the replies, however, I gather that the alternators with iron in the armature are deemed in this respect the more comfortable machines to have on hand. Somewhat akin to this point is that of a short-circuit on the mains during the parallel run, and I have taken some pains to discover the effect upon the alternators when they are of different inductance. This difference occurs most markedly in works like those of the City of London, where alternators without iron in the armatures are run in parallel with those containing iron. It also occurs in a lesser degree wherever machines of different types are in use.

It was once deemed very unsafe to run in parallel machines of widely differing inductances, and I remember the trepidation with which in the early days we ran in the works of the old Brighton company a Mordey in parallel with an E. C. C. alternator. I believe I am right in stating that when, four years ago, the City Company were very pressed for plant, having British Thomson-Houston machines at Wool Quay and Brush machines at Bankside, they tried, by way of experiment, the practicability of running in parallel through 1½ miles of

Digitized by Google

cable two such dissimilar machines as the Thomson-Houston and the Brush, and succeeding to their great surprise in doing so, the engineers continued the arrangement for the whole of one winter There was a slight fluctuation always perceptible in the light, due, no doubt, to the difference in the wave curve given by the two machines. With regard to the effect of a short, my experience is that when alternators of different inductances are connected in parallel, and short-circuit occurs, the machines of least inductance suffer first. This, however, may hardly be looked upon as an argument in favour of highly inductive alternators, since it may be urged that in alternating, as in continuous, current systems the translating devices should be so arranged that short-circuits in the mains or network are not a controlling feature in determining armature reaction.

Question 9.—Will the alternators run short-circuited?

With Iron in Armature.

Dublin.—(E. C. C. and L. and L.) They would to a certain extent, until the fuses went or the engines slowed down. I don't advise this as a regular practice.

Eastbourne.—(E. C. C. and L. and L.) They have run with a short-circuit on the mains, and have burnt it out without damage to the coils.

Southport.—(Mather and Platt.) These alternators during their full-load test were short-circuited up to 80 amperes without doing the slightest damage.

Tunbridge Wells.—(Kapp.) I believe so, due to the enormous amount of self-induction.

Woolwich.—(E. C. C. and Swinburne.) Cannot say, as engines would not drive them.

Without Iron in Armature.

Cheltenham.—(Siemens.) I don't think it would harm any of our alternators to short-circuit them for a few minutes. The pressure would drop enormously and the engine pull up.

Chelmsford.—(Crompton-Brunton.) No. (Mordey.) Not as at present wound.

Worcester.—(Mordey.) Yes.

Question 10.—What exciting energy in real watts do the alternators approximately take at?

With Iron in Armature.

Altrincham.—(M. E. S.) Full load, 2 per cent.; no load, 1·6 per cent.

Ayr.—(Siemens.) Full load, 1·4 per cent.

Blackpool.—(E. C. C.) Full load, 3·0 per cent.; no load, 2·5 per cent. (L. and L.) Full load, 2·0 per cent.; no load, 1·5 per cent.

Halifax.—(E. C. C.) 100 kilowatts—full load 2·4 per cent., no load 2·0 per cent.; 50 kilowatts—full load 2 4 per cent., no load 1·0 per cent.

Leeds.—(L. and L.) Full load, 2·0 per cent.; no load, 1·51 per cent.

Salford.—(Hopkinson.) Full load, 1·0 per cent.; no load, 3·0 per cent.

Southport.—(Mather and Platt.) 50 kilowatts—full load 1·15 per cent., no load ·5 per cent.; 25 kilowatts—full load, 1·6 per cent., no load 1·2 per cent.

Without Iron in Armature.

Bath.—(Mordey.) 1,220 watts, full load.

Bolton.—(Mordey.) 1·8 per cent., full load.

Bristol.—(Siemens.) 2 per cent. at full load.

Coatbridge.—(Mordey.) 572 watts at no load; 825 watts at full load.

Deptford.—(Ferranti.) From 2½ to 3 per cent.

Prescot.—(Two Brush, two Ferranti.) Brush—no load 700, full load 1,000; Ferranti—no load 1,800, full load 3,000.

Sheffield.—(Ferranti.) Ferranti, 1·75 to 2½ per cent. Ferranti, 1·4 to 2·1 per cent.

Question 12.—Do you employ any resistance or similar device to facilitate parallelings?

With Iron in Armature.

All reply "No," except Bristol, and there only when paralleling the gas plant.

Without Iron in Armature.

All reply "No," except Larne, where they do.

The next question (11) in reference to the efficiency of the plant is one of great importance. The task of the electrical engineer being to transform mechanical into electrical energy, the measure of the commercial success turns largely upon the efficiency of the plant.

Question 11.—Have you made any efficiency tests of the plant? If so, what was the nature of the test and the result?

With Iron in Armature.

Dublin.—(E. C. C. and L. and L.) Efficiency of conversion from indicated horse-power to electrical horse-power, 75 per cent.

Leeds.—(E. C. C. and L. and L.) 70 per cent.

Newport.—(L. and L.) 71 per cent.

Salford.—(Hopkinson.) Electrical output to indicated horse-power, 84 per cent. Commercial efficiency, about 92 to 93 per cent.

Tunbridge Wells.—(Kapp.) Indicated horse-power to electrical horse-power test was made, resulting in 73·9 per cent.

Woolwich.—(E. C. C. and Swinburne.) 120-kilowatt machine, commercial efficiency full load, 94 per cent.; 40-kilowatt machine, commercial efficiency full load, 90 per cent.

The other stations had no results to give.

Without Iron in Armature.

Bath.—(Mordey.) 80 per cent.

Bristol.—(Siemens.) No tests taken since preliminary tests at manufacturers'.

Bournemouth.—(Mordey.) The only tests made have been from indicator diagrams as compared with output under working conditions. The $\frac{\text{E.H.P.}}{\text{I.H.P.}}$ is about 80 per cent. at full load.

Deptford.—(Ferranti.) General works tests and comparisons between electrical output and indicated horse-power are made frequently, and show about 88 per cent. efficiency between engine and dynamo terminals.

Kingston-on-Thames.—(Siemens.) Efficiency of combined steam alternators: 25 kilowatts—full load 74·0 per cent., half load 68·8 per cent.; 50 kilowatts—full load 81·9 per cent., half load 74·6 per cent.; 100 kilowatts—full load 84·7 per cent., half load 77·2 per cent.

Prescot.—(Brush and Ferranti.) Brush plant engines and alternators 63 per cent. Full load, exclusive of exciting current, Ferranti plant, Browett-Lindley engine, and Ferranti alternators, 68 per cent. between steam-engine cylinder indicated and alternator terminals.

Sheffield.—(Brush and Ferranti.) Ferranti No. 1, commercial efficiency, 80 per cent. i.h.p.

Sunderland.—(Crompton-Brunton.) 73 per cent. ¼ load; 83·5 per cent. ½ load (from memory); 86 per cent. full load.

I regret that in forming this query I did not set out a basis of efficiency $\frac{\text{E.H.P.}}{\text{I.H.P.}}$ or $\frac{\text{E.H.P.}}{\text{B.H.P.}}$, and I think I shall be tempted, when revising the paper for the *Transactions*, to trespass once more on the patience of my friends for this information. As the data now stands it is somewhat puzzling. I confess myself ignorant of the term "commercial efficiency." $\frac{\text{E.H.P.}}{\text{I.H.P.}}$ I understand, and I gather that this works out:

Type I.—Dublin, 75 per cent.; Leeds, 70 per cent.; Newport, 71 per cent.: Salford, 84 per cent.; Tunbridge Wells, 73·9 per cent.

Type II.—Bath, 80 per cent.; Bournemouth, 80 per cent.; Deptford, 88 per cent.; Kingston, 84·7 per cent.; Prescot—Mordey 63 per cent., Ferranti 68 per cent.

These figures are most conflicting. I cannot understand how the first three percentages should differ, as the plant in the three places is almost identical. Several observations have convinced me that there is a difference of about 5 per cent. in the $\frac{\text{B.H.P.}}{\text{E.H.P.}}$ efficiency of the two types of plant. The commercial importance of this difference was illustrated lately by a negotiation in which I was recently concerned, where, with identically the same driving power, a copper disc machine was offered with a guarantee of 28½lb. of steam per kilowatt, as against 30lb. for an iron-armatured machine, the penalty fixed by me per pound being £100. High efficiency, however, ranks below safe, smooth working, and as the machine was intended to run in parallel, with iron-armatured alternators, I gave the preference to the type of the lower efficiency. I set out in this connection as a sort of *audi alteram partem* the record of burnt coils as far as it has been supplied to me.

Question 22.—Have any burnt coils occurred during 1895?

With Iron in Armature.

Altrincham.—(M. E. S.) At moment of paralleling one coil burst, but due to crack in ebonite insulation. During the parallel run none have failed.

Portsmouth.—(Ferranti and Parsons.) Once during the parallel run.

Without Iron in Armature.

Bournemouth.—(Mordey.) Burnt coils have occurred in alternators running singly and in parallel, but none at the moment of paralleling.

Hanley.—(Mordey.) Yes, but we do not care to publish particulars of any difficulties we may experience in running the plant.

Sheffield.—(Brush and Ferranti.) We have had coils burnt out at moment of paralleling, and during parallel run, and we have had them burnt out when the alternator was running singly. We have not lost any Ferranti coils yet.

Worcester.—(Mordey.) None at moment of paralleling. Occasionally during the parallel run, but none of them when running singly and on open circuit. No coils burnt out for five months.

Digitized by Google

The rest say "No." The next question is a crucial one.

Question 13.—Do you run in parallel only for switching-over purposes? If not, do you run in parallel every night?

Question 14.—What is the length of the parallel run?

With Iron in Armature.

Altrincham, Ayr, Blackpool, Bristol, Burton, Dublin, Halifax, Leeds, Newport, Portsmouth, Salford, Southport, and Tunbridge Wells are worked in parallel regularly.

Eastbourne.—(E. C. C. and L. L.) For switching-over purposes only. A few seconds.

Woolwich.—(E. C. C. and Swinburne). The alternators are always put into parallel for changing over, and are occasionally worked together, more particularly the Swinburne machines. Any of them work perfectly in parallel with either of the others. We have sometimes worked in parallel for five to six hours. I see no reason why they should not work for any time required.

Woking.—(Mather and Platt.) We have run in parallel regularly every night when load was high and could not be equalised easily on two separate circuits. With only two machines to run in parallel I do not think it well to do so, if you can arrange your circuits to avoid it. It is useful for switching over when a lot of machines have to be gradually shut down, but with two machines there is only one momentary blink if switched over without synchronising.

Without Iron in Armature.

Bolton, Bristol, Bournemouth, Cardiff, Cheltenham, Deptford, Hanley, Huddersfield, Kingston-on-Thames, Prescot, Sheffield, and Worcester run in parallel regularly.

Chelmsford.—(Crompton-Brunton and Mordey.) Only run in parallel for switching purposes or when convenient.

Coatbridge.—(Mordey.) At present we run in parallel for switching-over purposes. Gas-engine big, too unsteady to admit of continuous parallel working.

Exeter.—(Mordey.) Have only run in parallel experimentally.

Hampstead.—(Siemens.) We run in parallel for switching-over purposes, and shall run regularly in parallel when the load is sufficiently great to warrant running two or more machines. Time taken to change over at present.

Hence it would appear that among works running machines of type I., parallel running is almost universal.

With regard to the non-paralleling at some of the plants using copper disc machines, Messrs. Ferrantis points out that the list does not include any works where their plant is in use, and possibly the cause may be one entirely outside the question of iron *versus* no iron in the armature.

(To be continued.)

LEYTON ELECTRIC LIGHTING.

The following letter as to lamps has been sent by Prof. H. Robinson, of 13, Victoria-street, Westminster, S.W., to the Leyton Urban District Council:

Gentlemen,—At the outset of the introduction of electric lighting into Leyton I am anxious to prevent worthless lamps being used, and this can best be effected by explaining the conditions that should be complied with in ordering lamps. To make the matter clear, I may explain that the great majority of incandescent electric lamps are at present worked at a pressure of 100 to 115 volts, and, as a general principle, the higher the pressure at which the lamps can be worked, the greater will be the economy in distributing the current, and the greater will be the facility of regulating the pressure over the district. This principle is universally recognised and has led to a movement during the last few years in the direction of adopting lamps to work at higher pressures. In response to this feeling, the Board of Trade has recently been advised to permit current to be supplied to consumers at 250 volts pressure, whereas previously the limit was 150 volts. Inasmuch as the higher voltage is the most economical from the suppliers' point of view, it is necessary from the consumer's point of view to adjust the pressure to meet his legitimate requirements, which practically means "what pressure will enable lamps of 8 c.p. or 10 c.p. to be employed." There is no difficulty in making lamps of 32 c.p. and upwards to work at 250 volts, and there are numbers of 16-c.p. lamps now working at 220 or 230 volts, but a difficulty arises with 8-c.p. or 10-c.p. lamps worked at 200 volts and upwards which does not arise when the pressure is only 150 volts. As the 8-c.p. or 10-c.p. lamps are largely used for private lighting and for business premises, the 150-volt pressure that has been adopted at Leyton will meet that demand, and at the same time it will utilise the mains to better advantage than if 100 volts pressure had been adopted. A pressure of 220 volts would have worked with greater economy from the suppliers' point of view, but the requirements of the consumers must not be disregarded either as a matter of policy or of fairness, and I am of opinion that you will find in Leyton that a happy mean has been adopted which will be advantageous to both interests. The electric arc lamp has a very much higher efficiency than the incandescent lamp, giving from three to eight times as much light per unit of electricity used. The arc lamp cannot, however, be made for small candle-powers such as are required for domestic purposes, but it is frequently adopted with advantage in shops and for lighting shop windows. The ordinary arc lamp works with a pressure of about 50 volts, and therefore three lamps can be worked "in series" with current supplied at 150 volts. The standard pressure of supply is fixed at a multiple of 50 in order to enable consumers to work arc lamps under the most favourable conditions. Thus, if anyone requires 300 c.p. or 400 c.p. or more, and can conveniently arrange for the light to be supplied at three points, the arc lamp can be adopted with advantage, and will cost less than any form of gaslight yet invented. I have been in communication with the leading firms of lamp manufacturers with a view to your obtaining the best incandescent lamps for the district and preventing worthless lamps being foisted upon consumers. Some of the makers prefer a single filament and some double filaments, and I advise your ordering both for the lamps that are required in the public buildings and also for the streets. This will give an opportunity to lampmakers to supply a first-class lamp, and it will assist the private consumers in regard to the adoption of a type of lamp that has been proved to have a good record.

COMPANIES' MEETINGS AND REPORTS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

The interim report to the shareholders for the half-year ended December 31, 1895, has been issued, as promised at the last annual meeting of the Company. The report says the works have been fully employed on central-station and other orders. No large contracts have been entered into, but the volume of smaller orders has been well maintained, and additional large contracts are in course of negotiation. The new type of direct-driven alternating plant has proved satisfactory, recent tests made by Prof. Kennedy and S. P. Thompson for the Dover Electricity Supply Company having yielded very good results, both as regards the economy and efficiency of the machinery supplied by the Company. A specially favourable feature to which attention is drawn is that the machines remain practically cold after a prolonged run at full load. Negotiations are proceeding for an amicable settlement of the Company's claim against the City of London Electric Lighting Company for plant supplied. The Company's Austrian and Australasian branches are showing improved results. The development of electric traction is being actively pushed forward, and important orders are anticipated from this source. The new high-speed engine designed by the Company's chief engineer has been fully developed and tested, and has given satisfactory results. Steps are now being taken to place it upon the market, and the directors anticipate a large sale of these engines for general application, as well as for electrical purposes. The Board are making efforts to institute and maintain economies in every department. With this object the policy of concentration at the works at Loughborough, Leicestershire, which has been referred to in several of the recent reports to the shareholders, is being consistently followed as opportunity arises, by expiration of leases or otherwise, for the disposal of the London premises. Though these economies will not make themselves fully felt during the present financial year, their ultimate result upon the administrative charges of the Company will be of a very substantial character. During the half-year the issue of £105,000 4½ per cent. redeemable second mortgage debenture stock, mentioned in the last report, has been offered to the shareholders and £76,770 has been allotted. The balance is held in reserve for issue at a premium when necessary, but the Company's funds are ample for all present requirements. The directors do not propose to declare an interim dividend, preferring to await the result of the complete financial year, which closes on June 30.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY, LIMITED.

Directors: T. O. Callender (chairman), Alfred Pitman, B. H. Van Tromp, C. J. Wharton, J. B. Wood, Ernest Pitman. Secretary: Wm. Jeffery. 2 Northumberland-buildings, Bath. Engineer and manager: G. F. Metzger, A.I.E.E.

Report of the directors and statement of accounts for the year ending December 31, 1895:

During 1895 the gross profit has amounted to £1,570. 8s. 3d., and at the same time a much more efficient service has been given to the consumers. After the payment of bank charges and mortgage and debenture interest, there remains a net profit of £1 131. 0s 3d. To this must be added the sum of £388. 0s 9d., balance of profit brought forward from 1894, giving a total of £1,519. 1s. This sum is sufficient to pay a 4 per cent. dividend on the ordinary share capital of the Company, and to carry forward about £150; but your directors consider it expedient to place this profit to a reserve account, after the payment of the directors' fees. The increase in the business of the Company during last year has been of the most substantial and gratifying character. The revenue from the sale of current and from installations, etc., has risen from £5,067 in 1894 to £6,152 in 1895, an increase of £1,085. An all-day and night supply of current has been kept up throughout the year, and the increase in the profit over 1894 has taken place notwithstanding this additional supply involves a

Digitized by Google

serious loss throughout the summer months. The number of lamps connected is now 11,231, being an increase of 2,904 over the number installed at the end of 1894. The existing station plant is now well loaded, and directly the question of a provisional order is settled, your directors will consider the advisability of putting down plant for an additional 15,000 lamps, for which they believe there is ample demand. As in former years, all the expenses of keeping the plant in good condition have been charged against revenue. The running of the plant throughout the year has been most satisfactory, and it is now in the highest state of efficiency. In consequence of the opposition of the Bath Urban Sanitary Authority to the Company's application for a provisional order, a Board of Trade enquiry was held in Bath last March, with the result that the Board of Trade could not see its way to dispense with the consent of the local authority to the Company's order. Last November, this Company again gave notice of its intention to apply for a provisional order, and the local authority also made application for a provisional order, in almost similar terms. As the result of both these applications a meeting was held, at the invitation of the Board of Trade, between the Company and the authority, at Whitehall, on February 19, at which Sir Courtney Boyle proposed the appointment by the Board of Trade of an independent valuer to report to the Board of Trade on the value of the Company's property. Your directors at once agreed to this proposal, and they learn with pleasure that the Bath authorities have also concurred in it. They trust this independent valuation may prove useful in bringing the two parties to an agreement. Mr. B. H. Van Tromp is the retiring director and offers himself for re-election.

BIRMINGHAM ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: Henry Buckley (chairman), Geo. S. Albright, J. F. Albright, G. H. Johnstone, Francis W. V. Mitchell, J. C. Vaudrey (managing director).

Report of the directors submitted to the shareholders at the ordinary general meeting of the Company held at the offices of the Company, 14, Dale-end, Birmingham on 12th inst.:

The amount of net profit, including the balance of £1,001. 11s. 9d. brought forward from last year, is £6,570 11s. 8d. Out of this your directors recommend the payment of a dividend of 4 per cent., absorbing £3,629. 9s. 9d., placing £1,920. 9s. 11d. to the credit of the depreciation reserve fund, and a further sum of £250 to the general reserve fund, carrying forward the balance of £770. 12s. to next year's account. On making the above appropriation the total reserves and undivided profits will amount to £9,463. 18s. 6d. There has been a steady increase in the Company's business during the past year, the total number of 16-c p. lamps or their equivalent on order December 31, 1894, was 12,138, and on the same date in 1895 the number was 18,199. The additions since the close of the financial year have brought the number up to 19,401. The expenditure on capital account during the past year has been £50,537. 2s. 1d. Considerable additions have been made to the plant and machinery at the Dale End works. Included in the capital expenditure are the buildings and partial equipment of the Company's new stations at Edgbaston and Newhall street, as also the underground mains that have been laid through a considerable portion of the Company's new parliamentary areas. The directors are pleased to report that the two new stations are now in full working order. In the Edgbaston district the supply has been only available since October last, and the orders already received are encouraging. In the jewellers' district the demand for current, both for lighting and power purposes, considering the very few weeks the supply has been on the mains, is most satisfactory. The reduced scale of prices adopted by the Board last year has had the effect of increasing the number of consumers and augmenting the Company's business, and the slight falling off in the revenue caused by these reductions has now been overtaken, and justifies the policy adopted. The increase during the year in the use of motors has been considerable, and will no doubt in time become an important addition to the Company's resources. To cope with the output in the future, additional plant has been ordered for the equipment of the Dale End station, and generating plant is in hand for the Newhall-street depôt. As authorised by the shareholders at the last annual meeting, the registered capital of the Company has been increased from £100,000 to £200,000, and in October last 10,000 shares were issued at a premium of 5s. per share, and in accordance with the resolution passed at a special meeting of the shareholders the £2,500 received for the premium has been applied as follows: to writing off preliminary expenses, £1,685. 2s. 4d.; to writing off expenses incurred in the recent registration and issue of new capital, £154. 10s.; and the balance towards the reduction of the charge on account of the Company's provisional orders, £660. 7s. 8d. In accordance with the articles of association, two directors, Mr. H. Buckley and Mr. F. W. V. Mitchell, retire by rotation, and are eligible for re-election. The auditors, Messrs. Sharp, Parsons, and Co., also retire, and are eligible for re-election.

BALANCE SHEET, DEC. 31, 1895.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Aberdeen.—The Corporation invite tenders for an additional engine of 300 h.p. at the electric lighting station.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, Avenue Hoche 8, Paris.

Wallasey.—The Urban District Council want tenders by April 6 for alternators, concentric cables, and transformers. Particulars will be found in our advertisement columns.

Bedford.—The Electric Lighting Committee desire tenders by April 4 for a 240-h.p. compound engine and 150-unit alternator. Particulars are given in our advertisement columns.

Aston Manor (Warwickshire).—The Urban District Council require tenders for a high-speed vertical engine and dynamo for the improved lighting of the baths The estimate is £350.

Namur.—Tenders will be received on July 10 next for the construction of a telephone building at Namur. Plans and particulars can be obtained from le Service Téléphonique, Namur.

Duisburg (Germany).—The Municipality require tenders before March 23 for the electric lighting work for their new swimming-bath. Particulars can be obtained for 2 marks (2s.) from the Stadtbaurath, Duisburg.

Brussels.—Tenders are wanted for the supply of a large quantity of stores and fittings and apparatus (12 lots) for electric lighting. Specifications and particulars can be obtained at the Brussels Bourse, and tenders must be in by March 25.

Rotterdam.—Tenders are required by the Rotterdam Gas and Electricity Works for the supply of 75,000,000 kilogrammes of gas coal. Particulars for 10 cents (2d.) from Buch-händler Wed. P. van Weasberge en Zoon, Rotterdam. Tenders to be sent in by March 18.

Paris.—The supply of a telephonic switchboard for the office in the Rue Chaudron is open to tender. Application must be made by March 17 to the Direction générale des postes et des télégraphes, Rue de Grenelle 103, Paris, and tenders will be wanted by March 31.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Glasgow.—Tenders are required by the Corporation for a compound dynamo machine for the sewage purification works, Dalmarnock. Specifications and forms of tender may be had on application to Mr. Thomas Melvin, manager at the works, and tenders, properly sealed, and marked outside "Tender for Dynamo Machine," must be lodged with Mr. J. Lang, clerk, City Chambers, Glasgow, by 14th inst.

Aylesbury.—The Aylesbury Urban District Council invite tenders for lighting the several public lamps and the clock tower within the district of the Council for six months ending September 29. The conditions for lighting and all other particulars in connection therewith may be obtained on application to Mr. George Fell, clerk, Aylesbury, to whom tenders must be sent by 19th inst.

Altona.—Tenders are wanted by the Prussian State Railway Department for the supply of 93,000 arc light carbons and 16,000 incandescent lamps for direct and alternating currents during the year 1896-97. Tenders must be made upon official forms which, with the necessary particulars, can be obtained for 50pfg. (6d.) at the Centralbureau (Verwaltungsgebäude, Zimmer 67), der Königliche Eisenbahn Direktion, Altona.

Leeds.—The Electric Light Company invite tenders for the various works required in the extension of the electric light station in Aire-street, Leeds. Plans and specifications at the offices of the company, Aire-street, and bills of quantities on application to Messrs. Milnes and France, architects, 99, Swan-arcade, Bradford, until 19th inst., on which day sealed tenders, properly endorsed, are to be delivered to the architects by 6 p.m.

Paris.—The Direction générale des postes et des télégraphes, rue de Grenelle 103, Paris, require tenders for the supply of 10-millimetre and 16 millimetre paper tape for telegraphic instruments. Application for permission to tender must be made to the Direction by March 14, and tenders sent in by March 24. Tenders are also wanted for nine lots of apparatus for telegraphic offices. In this case application must be made by March 15, and tenders sent by March 25

Herne (Germany).—It is proposed to make a street railway nine kilometres (5½ miles) long from Herne to Recklinghausen, to be worked either by gas motors or electric traction. The undertaking will be put out to general competition, and the contractor will have to covenant for its completion in from one to five years. Tenders must be sent in by March 18, and particulars, price 1 mark (1s.), can be obtained from Herr Amtmann Schaefer, Der Vorwaltungsausschues, Herne.

Manchester.—The Manchester, Sheffield, and Lincolnshire Railway Company invite tenders for the supply, during twelve months ending April 30, 1897, of telegraph materials. Patterns can be seen on and after March 9, on application to Mr. A. W. Longden, storekeeper, at Junction-street Mills, off Ducie-street, London-road. Manchester; and specifications, with forms of tender may be obtained on and after same date, from Mr. Oliver S. Holt, secretary, London-road Station, Manchester. Applicants are requested to particularise the stores for which they wish to tender. Sealed tenders, endorsed "Tender for ——," to be in the hands of the secretary by 10 a.m. on March 17.

Chesterton (Cambs).—The Urban District Council is open to receive tenders for the public lighting of the district for seven years The tenders shall be made in the three following modes—namely, (*a*) lighting the district from August 14 to May 15 (inclusive) in each year; (*b*) lighting the district throughout the whole year commencing May 15 next; (*c*) lighting the district for either of the above periods (1) with ordinary burners, (2) with incandescent burners, if the illuminant with which the tender be made be gas. All cleaning, lighting, and maintenance to be done by the contractors Tenders to be sent to Mr James Spearing, clerk, 15, Sydney-street, Cambridge, by March 31.

Bradford.—The Corporation invite tenders for the following plant and machinery—viz.: (1) batteries: (2) surface condensing plant; (3) cables; (4) travelling crane; (5) steam and exhaust pipes. Forms of tender and specifications may be obtained on application to the electricity office, Town Hall, Bradford, on paying a deposit of £1 for each specification, which will be returned on receipt of a bona fide tender. Tenders, to be endorsed "Tender, Electricity Works," and addressed to the chairman of the Gas and Electricity Committee, and delivered at the town clerk's office, Bradford, by 25th inst. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages.

Bangor.—The Corporation invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough The contract will be split up into two sections: (1) construction, supply, and erection of boilers (water-tube), steam-engines (double acting), steam and exhaust pipes, etc, economiser, feed pumps, condenser, alternators, exciters, accumulators, switchboard, travelling crane; (2) supply and laying down of mains and transformers. Specifications and plans may be obtained on payment of £2. 2s. for the former and £1. 1s. for the latter, which will not be returned, at the office of Mr F. Hastings Medhurst, M.I.E E., Westminster-chambers, 13, Victoria-street, S.W. The firm whose tender is accepted will be required to enter into a contract and a bond with two approved sureties for the due performance of the contract. Firms may tender for one or both sections, but tenders for a part only of either section will not receive consideration. Sealed tenders, endorsed "Electricity," to be delivered at the office of Mr. W. H. Pritchard, town clerk, Bangor, by March 18.

Bucharest.—The Communal Council require tenders for lighting the suburban districts of the city by some system which shall not require to be conveyed underground by means of pipes or otherwise, and which shall, in the opinion of the Board, be considered the most advantageous of all the systems submitted, with a view to substituting same for the 3,265 oil lamps now used for lighting the suburban streets and squares The contract shall be given in accordance with the specification relating thereto, which has been drawn up by order of the Board of Technical Works, and approved by the Communal Council at a meeting held on January 24 The specification may be inspected any day during business hours at the office of the Agence Havas, 96, Queen-street, Cheapside, London, E C. The contract to be given for a term of five years from April 1-13, on which date the present contract runs out. Sealed tenders will be received from the 14th to 26th inst. Applicants must, in their tenders, refer to the items provided in Article 6 of the specification. All persons desirous of tendering are requested to attend at the Mairie on the day and hour above mentioned and lodge security for 15,000fr., failing which they will not be allowed to tender. The tender to be governed by Articles 68-79 of the General State Accounts Act.

RESULTS OF TENDERS.

London, W.—The following tenders have been received for electric lighting, wiring, fittings, etc., in connection with the new St. Marylebone Public Baths and Wash-house:

F. A. Donnison and Co.	£2 050	0	0
F. Suter and Co.	1,950	5	4
H. South	1,950	0	0
Roger Dawson and Co.	1,681	3	7
Emanuel and Co.	1,666	0	0
Strode and Co.	1,633	10	5
L. Alwyn	1,422	0	0

Buckingham.—The Town Council have, on the recommendation of the Lighting Committee, accepted the supply of electric lamps on the same terms as last year.

Liverpool.—The tender of Messrs. Craven Bros., of Manchester, has been accepted for erecting an overhead travelling crane at the electric lighting station at Liverpool.

Keighley.—The Keighley and Bingley Joint Hospital Board have accepted the tender of the Keighley Electrical Engineering Company for fitting up the hospital buildings with telephones.

Bradford.—The Town Council have accepted the tender of Messrs. John Brown and Co, Limited, to supply and fix two steam boilers at the new electricity works at Valley-road, for £3,000.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,777.

Great Northern Telegraph Company.—For the month of February the receipts were £22,000

Wells.—The Town Council have decided to apply for sanction to a loan for £10,000 for the installation of the electric light.

Westphalia.—It is intended to prohibit the firing of safety explosives in the coal mines otherwise than by means of an electric current.

Bingley (Yorks).—The Outer District Council have decided to request the National Telephone Company to place a telephone in the Council's office.

Buckingham.—The Town Council have decided to accept the supply of electric lamps from Messrs. Gillies and Hornidge on the same terms as last year.

Bengal.—A scheme for lighting Belvedere, the official residence of the Lieutenant-Governor of Bengal by electricity has received the sanction of Government.

Thornhill (Yorks).—The Urban District Council have decided to have the house of the waterworks inspector connected by telephone in case of emergency.

Leeds.—The Highways Committee have decided to proceed with the laying of the electric traction from the Canal Gardens to Kirkstall with the least possible delay.

Canterbury.—The Electric Light Committee have before them the report of the engineer on the introduction of electric light to the city at an initial cost of about £14,000.

Chelmsford.—The Essex Standing Joint Committee have decided to construct telephonic communication between the shire hall and the house occupied by the police sergeant at Widford.

Newcastle-on-Tyne—The Town Improvements Committee do not recommend the Council to carry out the doubling of the single lines of the tramways authorised by the Act of 1892.

St. Helens.—The Gas and Lighting Committee of the Corporation have decided to accept the tender of Mr. W. Molyneux, of Parr, for the erection of the new electric lighting works.

Southport.—At the monthly meeting of the District Highway Board Mr. Orritt presented a detailed plan of the positions of the proposed telephone posts at Formby, which was approved.

Monifieth (Forfarshire).—The Police Commission have resolved to hold a public meeting on an early date to consider the whole matter of lighting, either by gas, electric light, or other illuminant.

Wolverhampton.—The Lighting Committee's estimate for lighting, etc., street lamps is £159 in excess of last year. Provision is made for the increase in the number of electric lamps from 42 to 51.

Weybridge—A communication has been received by the Urban Council from the Board of Trade announcing the fact that the order of the Weybridge Electric Supply Company had been revoked.

Wakefield.—At the meeting of the City Council a discussion ensued on the proposed electric lighting works, and Alderman Sherwood said the committee hoped shortly to commence building operations.

Minster (Kent).—At a meeting of the Guardians Dr. Flint enquired if anything was being done in regard to the question of electric light. Mr. West replied that the committee were making enquiries in the matter.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending March 8 amounted to £1,040, as compared with £937 in the corresponding week of the previous year, being an increase of £103.

Halstead (Essex).—At the Urban District Council meeting the surveyor reported that Messrs. Crompton had sent one of their engineers to Halstead on February 20 and he had inspected the town, but his report had not yet been received.

Kingswood.—At the meeting of the Urban District Council a letter was read from Messrs Lawrence and Co., solicitors to the Council, stating that the provisional order for the electric lighting of the suburbs of Bristol would not be proceeded with.

Electric Lighting of Railway Carriages.—The new electrically-lighted carriages on the Great North of Scotland Railway have made their first journey to Elgin. During the whole journey from Aberdeen, the electric light remained steady and no hitch occurred.

Eastbourne.—The balance sheet of the Eastbourne Electric Light Company, Limited, shows a gross profit of £3,182. 2s. on the year. A dividend will be paid of £7. 10s. per annum, free of income tax, and £557. 5s. will be carried forward to next year's account.

Longton—The Town Council have given their consent to the provisional order of the North Staffordshire Tramways Company, and have appointed a sub-committee to consider the offer of the tramways company to work the existing lines in the borough and report thereon.

Nottingham.—The recommendation of the Electric Lighting Committee to expend £40,000 in the extension of the electric light works having been agreed to, application is being made by the Town Council to the Local Government Board to sanction the raising of the additional capital.

Garston (Lancs.).—The Urban Council have decided to ask the promoters of the Electric Lighting Bill for the district whether they would be willing to reduce the maximum price to 8d., the same as in Liverpool, and, further, within two years to supply any part of the district when requested by the Council.

Kidderminster and Stourport Electric Tramway.—The Great Western Railway Company have deposited in the private bill office of the House of Commons a petition praying to be heard by counsel against this Bill when the committee stage is reached. The Bill has been read a second time in the House of Commons.

Direct Spanish Telegraph Company, Limited.—The Board have decided, subject to audit, to recommend the payment of a dividend of 10 per cent. per annum on the preference shares and a dividend, free of income tax, at the rate of 4 per cent. per annum on the ordinary shares, both for the half-year ended December 31, 1895.

Belfast.—There has been some amount of correspondence in the local Press on the subject of the tramway service. Mechanical traction is desired, and the electric overhead system has been suggested. The deputation which visited Continental and English towns where electric traction is in use has returned and will report shortly.

New Book.—Under the title of "Future Trade in the Far East," Messrs. Whittaker have in the press for production early in the current month, a book by Mr. C C Wakefield, F.R.G.S., which will deal solely with commercial matters in China and Japan; particular attention being given to the Trans Siberian Railway now in progress.

Temperary Installation.—For the occasion of the annual assault-at-arms of the London Scottish Rifle Volunteers this (Friday) evening, a temporary installation of the electric light has been put in at the headquarters, James-street, Buckingham-gate, S.W., by Messrs. Lovelock, Seabourne, and Lee, Mare-street, Hackney.

City and South London Railway.—The returns for the week ended March 8 were £977, compared with £971 for the corresponding period of last year, being an increase of £6. The total receipts for the half-year terminating as above were £9,837, compared with £9,911 in the same period of the preceding year, being a decrease of £74.

Hull.—The Finance Committee have received a letter from the Local Government Board declining an extension of the period for the repayment of a loan of £8,000 for electric lighting purposes sanctioned in November last. It was explained that the loan was for machinery, and that in refusing the application the Board was carrying out its usual practice.

The Colonial Lighting Syndicate.—This syndicate has been formed with a capital of £2,000 divided into 40 shares of £50 each, to contract for the acquisition in Australia, New Zealand, Tasmania, or any islands or countries near thereto, gasworks and gas undertakings, and to contract for the supply of gas, electric, or other artificial light in these countries.

Goole.—The Aire and Calder Navigation Undertakers intend to introduce a system of electric lighting on their dock property at Goole. Hitherto the quays have been illuminated by gas supplied from the works which have been owned respectively by the Aire and Calder Navigation, the Goole Gas and Water Company, Limited, and at present by the Urban District Council.

Bury St. Edmunds—At the Town Council meeting, the Electric Lighting Committee reported that Mr. Medhurst's report on his scheme for lighting the town by electricity had been discussed, and enquiries were made of him on various points connected with the scheme. It was resolved that Mr. Medhurst be asked for a further report and supplementary estimate.

Mevagissey (Cornwall)—It is proposed to celebrate the inauguration of the electric light in the streets, and a committee has been appointed to confer with the Parish Council with reference to the suggested demonstration. It is expected that the streets will be lighted by the 24th inst., and Mr. Headley, of the electric works, has promised an electrical exhibition and a lecture on "Electricity."

Foxfield (Lancs.).—There is a proposal to construct a light railway through the Duddon Valley, and it is stated that electric traction on the overhead wire system could be very cheaply worked, because there is a sufficient fall of water from Seathwaite Tarn to supply all the energy that would be required to run electric cars. Besides, the valley would lend itself to a gradual gradient from Seathwaite to Foxfield.

Marylebone (London).—The Vestry have resolved, on the motion of Mr. Brooke Hitching, chairman of the Electric Light Committee, to substitute arc lamps for the gas lamps in Upper Regent-street from Oxford-circus to the Langham Hotel. The cost of these lamps will be £180 per annum, and they will give a light of 6,000 c.p. At present £150 per annum is paid for the gas lamps, which yield but 850 c.p.

Chesterton (Cambs).—The clerk to the Urban District Council has received a letter from the Cambridge Electric Lighting Company, stating that the company had carefully looked into the question of their powers, and had found that they were not empowered to light beyond the municipal boundary of Cambridge. They, therefore, regretted their inability to tender for the public lighting of the Chesterton district.

Chester.—At the Town Council meeting the Mayor, as chairman of the Electric Lighting Committee, said the estimate for the machinery and the dynamos had been increased on the recommendation of Prof. Kennedy by about £1,400, making the total amount for the machinery and plant about £15,600. The total amount for the electric lighting, including the additional £6,000 over the original estimates, would now be within £22,000.

Digitized by Google

Ilfracombe.—At a meeting of the District Council a letter was received from the National Telephone Company asking whether the Council would agree to join the exchange. This was deferred for future consideration. An application by the same company for permission to erect poles on the Lee-road was made, and the clerk was directed to say that many of the roads were so narrow that the company should apply to the landowners adjoining.

Bristol.—At a special meeting of the St. George Urban Council a deputation was received from the tramway company in response to the chairman's motion, "To petition the Bristol Tramway Company in favour of their fares on the electric tramway being altered from 4d. to 3d. fares." After a brief discussion Mr Butler announced that the company would accede to the request, which should come into operation as soon as the new tickets, etc , could be prepared.

Dudley.—At a meeting of the Town Council Councillor Hughes remarked that there had been a change in the directorate of the gas company, and they might get some concessions. If not. they might consult with electrical engineers to light the town with electricity. He was a shareholder in the gas company, but he agreed that the price charged for gas was higher than it should be It was ultimately decided to refer the matter to the Streets and Gas Committee.

Bromley —At a meeting of the Urban District Council a letter was read from Messrs. Waterer and Dickens in regard to the proposed electric lighting syndicate, stating that the letter from the Council was so out of keeping with the views expressed by the committee who interviewed the delegates that they were surprised. Their clients would not meet again for some little time, and they hoped the Council would still consider them in treaty for the acquisition of the provisional order.

West Bromwich.—The correspondence relative to the South Staffordshire Tramways Company and their communication with the Board of Trade making formal application for an extension for the use of steam on their lines has been submitted to the Town Council. It was embodied in the report of the Highway Committee, who added that a letter had been received by them from the local tradesmen's association, advocating the cable system and protesting against the electric overhead wires.

Haslingden —At a meeting of the Town Council it was moved by Councillor Bentley, seconded by Councillor Barlow, and resolved that the town clerk take the necessary steps to obtain the provisional order under the Electric Lighting Act. It was further moved by Councillor Baxter, seconded by Alderman Barlow, and resolved that Alderman Holt and Collinge and Councillor Bentley be appointed to confer with the town clerk, and obtain all necessary information in connection with such proposed provisional order.

Bell's Asbestos Company.—The report of Bell's Asbestos Company for 1895, to be laid before the general meeting in London on March 19, states that the result of the year's operations is a net profit of £3,207, to which has to be added £3,593 brought forward, making a total of £6,800. After placing to reserve fund £1 000, there is left for appropriation £5,800. The directors recommend the payment of a dividend at the rate of 3 per cent. per annum, free of income tax, and the carrying forward of £2,200.

Lambeth (London) —The Ratepayers' Association at their last meeting congratulated themselves on the Vestry having handed over the electric lighting order to a private company, and so rid themselves of a costly experiment. One gentleman, however, moved a vote of censure on those vestrymen who had voted for handing the electric light over to a private company. He thought Lambeth should have gladly seized the opportunity of striking a blow at monopolies, but he only got two members of the meeting to support him.

Edinburgh.—The Electric Light Committee of the Town Council have had under consideration the appointment of an electrical engineer in room of Mr. Monkhouse, who has resigned. There were over 70 applications for the post, and from these Prof. Kennedy has made a selection of six. The committee unanimously recommended the Council to ask Prof. Kennedy to become a permanent official of the Corporation, and as chief engineer to advise upon all points in connection with the installation. His salary will be £200 a year.

Worcester.—At a meeting of the City Council, Alderman Williamson proposed that the accounts of the electricity department for 1895 which had been published be approved and forwarded to the Board of Trade. He said he thought the Council must have been agreeably surprised to find that they had not sustained the heavy loss which they had been led by some members of the Council to believe they were sustaining, and that the amount which had been expended was not so much as many members thought. The motion was carried.

Burslem.—The Council have unanimously confirmed resolutions of the Tramways Committee authorising the town clerk to lodge with the Board of Trade the formal consent of the Corporation to the provisional order of the Potteries Extension Tramways, and directing the corporate seal to be affixed to an amended agreement with the promoters of the extension tramways, and to an agreement with the North Staffordshire Tramways Company that the power of the Town Council to purchase the company's undertaking be postponed for 21 years from August 1 next.

Belfast.—Mr. V. A. H. M'Cowen, engineer, attended at the last meeting of the Electric Committee, and was heartily congratulated on his recovery from his recent severe illness. He submitted tenders for the supply and erection of a compressed-air engine starter, and that of Messrs. Kerr, Stuart, and Co. was accepted. A letter was read from the Board of Trade with copy of the new regulations made by the Board under the Electric Lighting Acts, 1882 and 1888, and the engineer was instructed to report as to these regulations as affecting the Corporation.

Vacancy.—The Uganda Railway Committee are in want of an officer to take charge of the erection and working of telegraphs. The salary is £400 a year, and applications should be made by letter only, and with copies of testimonials, to the secretary, Uganda Railway Committee, Foreign Office, Whitehall, London, S.W. No one need apply who cannot produce certificates showing that he has received a good general and professional education, the latter including the science as well as the practical part of his profession, and the applicant's age must not be less than 25 or more than 40 years.

Bridgend.—At the meeting of the Urban District Council a let er was read from Mr. J. C. Howell, Llanelly, in which he stated he was prepared to pay an amount equivalent to that which the Council had expended in obtaining the order for electric lighting, and would also proceed to put down the necessary plant, etc., for carrying out the undertaking. He would also give the Council the option of purchasing the undertaking after a certain interval on payment to him of the preceding years' profits. After a short discussion it was agreed that the letter be considered at a special meeting of the Council.

Portsmouth.—The balance-sheet of the Electric Lighting Committee for the year 1895 shows an excess of income over expenditure of £2,463 14s. 6d. In the case of a private company this would have enabled the directors to pay a dividend of 3¾ per cent., but as the committee have to pay off, in annual instalments of principal and interest, the money borrowed for the works, they are setting aside the year's profit for that purpose. This balance-sheet was prepared expressly for the Board of Trade. The one to be presented to the Council in April will be far more favourable, as the results of the working during this year are increasingly satisfactory.

Harrogate.—At the meeting of the Town Council it was stated by the town clerk (Mr. W. H. Wyles) that the Board of Trade had provisionally approved of the Harrogate Electric Lighting Order, 1891. A letter was read from the Local Government Board intimating that they could only sanction a loan of £27,000 for electric lighting on condition that the Council adopted the rules and regulations of the Board of Trade. The matter was referred to the Electric Lighting Committee. It was reported that the houses of the fire brigade have been connected with the station by telephone, and other steps taken to protect the town against fire.

London Lighting Extensions.—The County Council have given sanction to the following applications: From the House-to-House Electric Light Supply Company to lay low-tension mains in Thistle grove-lane, and high and low tension mains in Fulham-road, Warwick-road, and Earl's Court-square; from the Notting Hill Electric Lighting Company, to lay mains and to construct street boxes in Holland Park; from the Kensington and Knightsbridge Electric Lighting Company, to lay mains in Prince Consort-road and across Princes-gate; and from the Charing Cross and Strand Electricity Supply Corporation, to lay mains along Harvey's-buildings from a street box in the Strand.

Altrincham.—At a meeting of the Urban Council, Mr. J. Drinkwater moved the adoption of the minutes of a special meeting of the Highway and Lighting Committee. He said there was first the agreement which had been entered into by the Altrincham Electric Supply, Limited, with Ashton-on Mersey for the lighting of the township. The agreement was an excellent one, and if at any time Altrincham should wish to purchase the electric plant it would not be under any circumstances in any way bound by the agreement It was also resolved to write the Board of Trade and to inform them of the satisfactory arrangement made with the company. The minutes were adopted.

Coventry.—In the case of Jackson *v.* the Coventry Electrical Engineering Company, Mr. Justice North has had before him a motion in a debenture holders' action for the appointment of a receiver and manager of the assets of the company. Mr. Whinney said that the company appeared by Mr. Kenyon Parker, and consented to the motion. Mr. Justice North made the usual order in a debenture holders' action, and appointed Mr. Pearson receiver and manager by the same order, to act at once. Mr. Kenyon Parker mentioned that the plaintiffs held £200 of £800 debentures, and that there were current contracts pending, and considerable plant to the value of about £1,000. It was directed that Mr. Pearson's security should be completed forthwith.

Aston Manor (Warwickshire).—Owing to the inefficient and unsatisfactory character of the electric lighting plant erected at the baths three years ago, the Council have decided to duplicate the plant, and for that purpose have instructed their surveyor (Mr. H. Richardson) to obtain tenders for a high-speed vertical engine and dynamo. The estimated cost is £350, and application is to be made to the Local Government Board for sanction to a loan for that amount. The surveyor has also been instructed to have the telephonic communication altered at the Council offices by connecting each office, as well as the lines from the baths, hospital, fire station, and interception department, to one switchboard in the caretaker's department. The estimated cost is £50.

Plymouth.—The Electric Lighting and Municipal Offices Committees received 40 applications for the post of electrical engineer. After going through the testimonials they reduced the number of candidates to five, and appointed a sub-committee to visit the towns in which those candidates resided and make personal enquiries. As the result the joint committees unanimously recommended the appointment of Mr. J. H. Rider, of Bolton. Mr. Rider was 33 years of age, and had designed, supervised the

Digitized by Google

construction, and now had the sole management of the electric lighting installation in Bolton. At the meeting of the Council to which Mr. Rider was introduced, Mr. Radford moved his appointment, remarking that both committees were unanimous in the belief that they had found in him the best man for the position. Mr. J. Willoughby seconded the proposition, and it was carried.

Harrington (Cumberland).—At the meeting of the District Council Mr. Curwen moved that the question of the lighting of the district by electricity be considered. He would not speak at length on the matter, but proposed that they appoint a committee to obtain information as to the expense of lighting the district by electricity and report to the Council. It was the general opinion that electricity was the light of the future, and it would be a great benefit if it could be introduced at a reasonable expense. Mr. Thom seconded the motion. Mr. Rutherford did not think they could do anything in regard to electric lighting. He did not see why they should put more work on the surveyor, when there was no prospect of anything being done He proposed that the question of electric lighting be left out altogether. Mr. Johnston seconded. On a vote being taken, Mr. Curwen's motion was carried.

Hanley—At the meeting of the Town Council, the General Purposes Committee recommended that from and after January 1 last charges for electrical energy be made as follows: 5d. per unit to general consumers; 4d. per unit for churches, chapels, and other places requiring light principally on Sunday evenings; 3d. per unit for energy supplied for motive power; and that, in lieu of the discount of 5 per cent. hitherto allowed, an abatement of ½d. per unit be made on all accounts paid within 21 days from the end of the quarter. Mr. A. Wood, in moving that the recommendation be confirmed, said that these reduced charges would mean a loss of £511, to make up for which they would require additional current to the extent of 35,000 units. The recommendation of the committee was confirmed, with the exception that the discount was fixed at 5 per cent., instead of ½d. per unit.

Colchester.—The Electric Light Works Committee unanimously recommended the Council to appoint the mayor a member of the committee, and at the meeting of the Town Council Mr. Barritt moved the adoption of the report. Mr. Goody seconded, and the motion was unanimously carried. The Town Clerk said a letter had been received from the officer commanding Royal Engineers stating that he was directed by the Secretary of State to say that the War Department would be prepared to have the electric light for the blocks of officers' quarters and mess and the recreation establishment in the new barracks if the current could be supplied at a rate which should be satisfactory to the Secretary of State, but the question of lighting the whole of the new barracks must await the result of experiments being made elsewhere as to the suitability of such light for general barrack purposes. The letter was referred to the committee.

Hove (Brighton).—The annual meeting of the electric lighting company was held last week at Cannon-street Hotel, London, Colonel Filgate presiding. In moving the adoption of the report, a copy of which has appeared in a previous issue of this journal, the Chairman stated that the revenue from the sale of current had increased from £3,616 in 1894 to £5,343 in 1895. The number of lamps attached to the company's mains numbered 18,403 of 8 c.p., while the consumers were 270. The consumption of electricity was still increasing in their district, and the estimated net revenue for January and February of this year showed an increase of about 25 per cent. over that in the corresponding period of last year. The Board had decided to pay off the 5 per cent. debentures and to issue others bearing 4 per cent. Colonel Wood seconded the resolution, which was adopted A dividend at the rate of 4 per cent. per annum was afterwards declared.

Oxford.—There is an increase according to the Finance Committee's estimate of £272 in the amount required for lighting. There are already 32 arc lamps of 2,000 power in working order. The new municipal buildings are being installed with the electric light The dividend recommended by the directors of the Electric Company at the fifth ordinary general meeting of shareholders is 3½ per cent. on the ordinary shares; there has been a gross profit on the year of £2,709. 8s. 3d, and after providing for the full interest of 5 per cent. on the debenture issue and other interest there remained £1,317. 9s. 4d., which added to the amount brought forward from the previous year, £195. 4s. 8d., left an available balance of £1,512. 15s. The sum of £360. 3s. will be carried forward to the next account. To provide for extensions of the system, in consequence of the anticipated increase in the demand for current, the directors propose to issue 914 ordinary shares of £5 each.

Ayr.—At the meeting of the Town Council a long report was submitted by Mr. Hammond, the electrical engineer, in which it was stated that with the exception of the transformers the plant was in good order. With reference to the transformers which had proved defective, Mr. Hammond pointed out that in terms of the conditions of the contract the Corporation were entitled to reject them. It appeared that new contracts for efficient transformers had been entered into with Messrs. John Fowler and Co. It was agreed, on the motion of Mr Grant, that Mr. Hammond should be requested to furnish a supplementary report with regard to the temperature test of the defective transformers at the works of the contractors before delivery. It was intimated that Messrs. Callender and Co. had expressed their willingness to guarantee their cables for five years, and the Council agreed to accept the guarantee. It was agreed to apply to the Secretary for Scotland for power to borrow a further sum of £5,000 for the electric light.

Helensburgh.—The question of street-lighting has been discussed by the Police Commissioners. Mr. Bryden thought that, instead of extending the present antiquated system, the committee should rather be empowered to consider the lighting of the town with the electric light. The town lent itself naturally to that system, and they had a splendid water power. Bailie Duncan said they had already consulted an electrical engineer on the subject, and he rather discouraged it. The electric light cost three times as much as gas. The Provost thought the electric lighting of the town could be effected. He alluded to the case of Cape Town, which was lighted by water power, and the water afterwards used for domestic purposes. He had consulted an eminent gentleman in Glasgow on the subject, and he believed such a system would be practicable in Helensburgh at a small expense. When he had received more complete details he intended to lay the matter before the people. Mr Bryden's suggestion was agreed to.

Commercial Cable Company.—The report of the Commercial Cable Company for 1895 states that the gross earnings amounted to 2,009,738dol., and the working and other expenses to 794,340dol., leaving a balance of 1,215,398dol There was an increase in the earnings of 236,304dol., and an increase in expenses of 31,345dol, as compared with the returns of the previous year, resulting in an increase in net earnings of 204 959dol. Dividends of 1¾ per cent for the quarters ending March 31, June 30, September 30, and December 31 have been paid; a total of 7 per cent. for the year on the capital stock, amounting to 700 000dol. The reserve fund has been augmented by the purchase of 200 000.00dol United States Government bonds The balance of the year's profit, amounting to 315,398dol., remains to the credit of profit and loss. Six sections of the cables were interrupted at different periods during the year, chiefly caused by contact with anchors of fishing vessels. The repairs were, however, promptly effected. The whole system is in excellent condition.

Stafford.—At a meeting of the Town Council the Gas and Electricity Committee recommended that the electric cables be extended along Lichfield-road to St Paul's Church at a cost not exceeding £250, and that the two ¼in. feeders be extended from Tipping-street to Dr. Cookson's, in Lichfield-road, at a cost not exceeding £200. The engineer having conferred with the sub-committee of the County Council on the subject, the committee asked for sanction to an agreement with the County Council for the lighting of the County Council buildings, the Judges' House, and Eastgate House with electricity, a minimum charge of £43. 15s. per quarter to be made, with a further charge of 8d. per Board of Trade unit for all current consumed over 1,312 units per quarter, the number of lamps not to exceed 1,200 8 c.p. or their equivalent. These terms to be subject to revision at the end of 12 months. In moving the adoption of the report, Alderman W. H Peach said more revenue had been expected from the supply of electricity to the County Council buildings, but the terms were subject to revision at the end of 12 months. Alderman Silvester seconded the motion, which was agreed to.

Islington (London).—A description of the Islington electric light station appeared in our last issue, but the following particulars in reference to the boilers may be added. The mountings and valves of these are throughout the manufacture of J. Hopkinson and Co., Limited, Huddersfield. Each boiler is equipped with a patent "Duad" safety-valve for high steam and low water; a duplex safety-valve for high steam; a patent parallel slide-valve to steam-main; a patent steam-isolating valve; two accessible check-feed valves; a patent parallel slide blow-off valve with locking gland; an isolating blow-off valve; two sets of patent "Absolute" water gauges with safety shields; and one 10in steam gauge, with asbestos-packed cock, and syphon with connection for indicator or test gauge. The valves on the steam main feed pipes, pump-main, and exhaust-pipes are throughout Hopkinson's parallel slide-valves. We also omitted to state in our necessarily short description of the buildings that the whole of the skylights are glazed on the Rendle "Invincible" system. The effective nature of the lighting is at once noticed on entering the engine and boiler rooms. Skylights glazed in this way are practically indestructible.

Audenshaw—At the District Council meeting the Clerk observed that already the Council had given their approval to the Manchester Tramway Company's scheme, which proposed to do more than the Electric Tramway Company. The Chairman said that the Manchester company proposed to cover the whole of the road which the Council had jurisdiction over. Councillor Hamer said the Manchester company could not do anything as yet, because their provisional order would not be obtained until next session. Until then the company could not do anything. A Member: Providing the electric company make application this session, and get power, will it throw Manchester over altogether? The Chairman: I cannot tell you. The Clerk observed that there were already about 20 in opposition to the electric scheme. Councillor Hodgson: Supposing the electric company get their order and proceed with the work, Manchester cannot come in only by arrangement with the electric company. Councillor Hamer said their position was perfectly plain. Under certain circumstances the Council were prepared to support the electric scheme, but seeing that Manchester proposed to give them something more than the electric company, they were bound to support Manchester.

Sheffield.—The electric light and power company are fitting up the Langwith Colliery with the electric light. A powerful dynamo has been put down capable of lighting up the whole of the premises, both on the surface and under ground. The Parliamentary Committee have resolved, "That Messrs. Walter Webb and Co. be asked to state whether, having regard to the expressed desire

Digitized by Google

of the Sheffield Tramways Company to assist the Corporation in giving effect to its desire, their clients are willing to continue to work the tramways subject to 12 months' notice to be given at any time, but that under any circumstances the Corporation will prefer to pay the amount due to the company at the termination of the present lease, and that the Sheffield Company be informed that if they are prepared to negotiate with the Corporation on these lines, a conference between the committee and representatives of the company be forthwith arranged." At the same meeting a sub-committee was appointed for the purpose of preparing a scheme for the extension of the city tramways, to be submitted to Parliament in 1897, with power for the sub committee to obtain such professional advice in the preparation of the scheme as they may require. The Electric Light and Power Company have made a third call of £1 per share on the new capital they issued at the beginning of last year.

Bath.—The annual meeting of the shareholders of the Bath Electric Lighting Company has been held, Mr T. O. Callender, of London, presiding. The balance-sheet showed a gross profit for 1895 of £1,570, and the report was described as the most satisfactory ever laid before the company. At the commencement of the year a balance was brought forward of £388, giving a total sufficient to pay a 4 per cent. dividend and leave a surplus of about £150. The directors, however, considered it expedient to place the amount to a reserve account, after the payment of directors' fees. The Chairman, in moving the adoption of the report, referred to the contest between the company and the local authority. As a result of the recent conference of the company and the authority with Sir Courtenay Boyle, representing the Board of Trade, Prof. Kennedy had been appointed to act as valuer. Mr. Ruddock, a shareholder, asked on what ground the authority opposed their application for a provisional order. The Chairman remarked that this was what they could not understand. Mr. Titley, another shareholder, complained that the authority were attempting not only to preclude them from obtaining their provisional order, but were attempting to buy them out on the worst possible terms. A dividend of 3 per cent. was proposed by one of the shareholders, but the recommendation of the directors was carried by nine votes to six.

Guernsey.—Public meetings have been held in Guernsey, on March 4 at St. Peter-Port, and on March 5 at St. Sampson's, to consider the advisability of introducing a telephonic exchange system into the island. Both meetings were addressed by Mr. A. R. Bennett, who recommended that the work should be a popular one, undertaken either by the States of Guernsey or by a local co-operative company approved by the States. A representative of the National Telephone Company was present, and explained the terms on which his company would open a Guernsey exchange; these were, however, rejected as too onerous Ultimately the following resolutions were unanimously adopted: "(1) That it is expedient to introduce a telephonic exchange system into Guernsey with the smallest possible delay; (2) that a committee be appointed to consider the whole subject, and to take the necessary steps to bring about the establishment of an exchange by the States of Guernsey or by a co-operative company under the protection of the States." A committee consisting of 17 leading inhabitants, including several members of the Guernsey Legislature, was elected, partly at the St. Peter-Port, and partly at the St. Sampson's meeting. The committee held its first sitting on March 6, and decided that the States should be recommended to apply immediately for a license to telephone the island in terms of Clause 19 of the Treasury Minute of August 7, 1894. A telegram notifying the desire of Guernsey to manage its own telephone system and the intention to apply for a license was ordered to be despatched to the Postmaster-General.

Cork.—An enquiry has been held by Mr. W. W. Barrington, engineering inspector to the Board of Works, into the merits, from an engineering point of view, of the electric tramways scheme. Mr. Murphy said they proposed to make the tramways with a 3ft. gauge In the principal streets of the city they would have a 6in. sett pavement, with a bed of 6in of concrete. According to the specification of the Corporation on a recent occasion, when they intended to block pave one of the streets of the city, that was the sett proposed to be used. It was intended that the rails would weigh from 77lb to 80lb. a yard. They proposed in some of the streets on which there was less traffic to put in a lighter pavement of 4in. cubes. In the country they would have cross-sleeper rails 5in. deep and made up with ballast. They did not propose any pavement. On Parnell Bridge there would be a question to consider The bridge was 21ft. wide, and the promoters propose to run a double line over it. The city engineer recommended only one line, but his experience was that a double line was a greater convenience. The single line in the centre would be liable to block the traffic, while if there were two lines, one at each side, the tramcar would go with the traffic. The average length of the cars would be about 22ft. At the subsequent meeting of the Corporation the Mayor mentioned that the enquiry had been held and that the promoters had applied to the town clerk for a meeting of the Council at an early date at which they proposed formally to make application, and the probability was that a special meeting of the Council would be held towards the end of the month.

New Publications.—We have received a copy of the fifth edition of "Tabulated Weights of Iron and Steel." This is a good looking, though somewhat bulky pocket-book. compiled by Mr. C. H. Jordan for the use of naval architects, shipbuilders, and manufacturers, but the 578 pages of tables which make up this pocket-book contain information which will save much time and calculation on the part of all that have in any way to do with iron or steel construction. Messrs. Johnson and Phillips, of Old Charlton, send us an addition to their cable-list, giving particulars and prices of vulcanised rubber-covered and taped cables. Lastly, we have to acknowledge the receipt from the Brush Electrical Engineering Company, of 49, Queen Victoria-street, E C., of an advanced copy of a pamphlet they are issuing on the Raworth "Patent Universal High-Speed Engine." Though called a "pamphlet." this is really a substantially-bound and handsome-looking square book about the size of an ordinary blotting case. It contains an illustrated and detailed description of the Raworth engine and its accessories. This engine, it will be remembered. is essentially a tandem engine, the cylinders being arranged in pairs one above the other, and the valves placed between the cylinders. The engine figured in this pamphlet is of the compound single crank type, but it is also built with two cranks and two pairs of cylinders for triple or quadruple expansion. In the triple-expansion type the high-pressure and intermediate cylinders are over one crank, and two low-pressure cylinders over the other crank. In the quadruple-expansion engine the arrangement of the cylinder connection is similar to that of the compound.

Wimbledon—At a meeting of the Urban District Council a letter was read from the Local Government Board with reference to the electric lighting scheme, pointing out that they would not be prepared to entertain the proposal of the Council to borrow money until they had obtained from the Board of Trade a renewal of their license, and the Board would then only be willing to sanction a loan for the period over which the renewed license would extend. Mr. Crickmay said he would like to know why this difficulty had not been foreseen. The Clerk explained that during his long experience as clerk he had always found it to be the practice of the Local Government Board not to appoint an enquiry until they found everything in order. He thought he had reason for thinking previous to the enquiry that they were satisfied that the matter was in order, and that it only remained for the scheme to be heard on its merits. It was his impression that there had been an oversight on the part of the Local Government Board. The Chairman said the only thing they could do was either to wait until November for a provisional order or get their present license extended. There was a question whether the Board of Trade would grant an extension of the license for two years much before October. Mr. Crickmay asked why the Council should not apply for a fresh license before the present one expires. The Chairman said personally he saw no reason for not asking for an extended license forthwith, but the letter of the Board of Trade seemed to imply that they could not entertain their application until the expiry of their present license. Mr. Noller observed that they would have to wait about 15 months before they could get a provisional order. No action was taken.

Burton-on-Trent.—The electric light undertaking is gradually improving from a financial point of view. Alderman Low, at a meeting of the Town Council, made the following statement: The expenditure on capital account for buildings, machinery, mains, etc., during the year has been £1,626. 5s. 8d., which, with the amount previously expended—viz., £27,008. 6s. 4d , made a total capital outlay of £28,634. 12s. This sum includes the expenditure on the Ashby-road mains, amounting to £1,159. 2s. 4d. The amount of stock issued to that date was only £25,992. 17s , so that the capital account was overdrawn to the extent of £2 641. 15s,; during the present month, however, the new loan of £5 000 has been issued, leaving a balance now in hand of £2,358. 5s. for future requirements. The revenue account shows a total receipt of £1,050. 14s 3d., against £506. 18s. 5d. the previous 10 months, the working expenses being £1,342. 14s. 8d., against £843. 18s. 10d., showing a loss of £292. 0s. 5d., as against £337. 0s. 5d. The amount provided for dividends on stock and contribution to redemption fund was £1,487. 4s. 4d., the same as the previous year. Three per cent. stock, to the value of £707. 8s. 8d., has been cancelled, leaving the amount now outstanding at £25,285. 8s. 4d., but against this the sum of £741. 0s. 9d. is standing to the credit of the redemption fund account, of which £728. 15s. 5d. is invested at 3⅜ and 3¼ per cent , and the balance of £12. 5s. 4d. is in the hands of the treasurer. The total sum to be transferred from the general district rate is £1.779. 4s. 9d., against £1,802. 9s 3d. last year, the estimated amount being £1,860. The number of consumers at December 31, 1895, was 64, against 52 the previous year. He regretted that there were not more users of the electric light, and stated that until there were they could not expect to make any profit out of it.

Bradford.—The Town Council have adopted the minutes of the Electricity Committee. which included reports upon negotiations with the Guardians with a view to the lighting of the whole of the workhouse buildings by electricity; a resolution instructing the electrical engineer to proceed with the necessary alterations at the Bolton-road station for the purpose of adapting the works to the increased electrical pressure occasioned by the change from the two wire to the three wire system; and resolutions recommending the Council to authorise the committee to proceed with the letting of the contracts for the new electricity works, and to extend the area of the Corporation's electrical supply. Mr. Dixon, chairman of the committee, made his half-yearly statement with regard to the working of the department, and said it was progressing most satisfactorily, and was, he believed, exceeding in its results even the anticipations of its founder. The committee had added two new boilers, 300-h.p. engines made by Messrs. Willans and Robinson, and of the three-crank pattern, and also three 800-h.p. boilers made by Sir George Brown, and these were giving every satisfaction. The establishment of the three-wire system was rapidly approaching completion, and the greater part of

Digitized by Google

the borough, if not all of it, would soon be put upon the 230-volt basis. This would add to the revenue of the department, mainly from the fact that there would be less leakage from the high pressure than from the low pressure · During 1895 the committee had sold 373 372 units, as against 307,977 in 1894, the increase being 65.395 units, and the demand being still an increasing one. The committee had at the present station a total indicated horse-power of 2,210, and this power was very often taxed to its utmost capacity There was a profit upon this department, after paying interest and sinking fund and allowing for depreciation, of £1,792. 19s. 1d , as against £918. 10s. 5d., there being an increase of profit of £874. 8s. 8d.

Dundee.—A proposal to introduce the metallic-return system in the matter of telephone wires in Dundee has been considered at a meeting of the Works Committee of the Town Council. The following letter was submitted from the general manager of the National Telephone Company: "The Board of this company has at present under consideration the question of making certain alterations to and improvements in its plant in Dundee, and, amongst other things of placing the system on what is known as the twin-wire or metallic-return principle, which involves the provision for each subscriber of a second or return wire. To do this effectively, and to secure the greatest efficiency of service, it is essential that the main routes of wires in the centre of the town should be placed underground. Having regard to the great development which is taking place in the use of the telephone service for long-distance communication, and to the fact that the Post Office has either opened, or has now in process of construction, trunk wires connecting all the principal towns in the United Kingdom, the Board has arrived at the conclusion that the time has come when the works which I have indicated ought to be undertaken, and it is ready to undertake them if the Corporation will afford the requisite assistance. As regards the interference with the streets, the company has no desire to obtain any rights therein adverse to the Corporation, and is indifferent as to how the work is done. I venture to suggest that a committee of the Corporation should be empowered to receive the representatives of the company, when the matter could be fully discussed and proper explanations given." The committee received the proposal with great cordiality, and appointed a committee to meet the representatives of the National Telephone Company. The rental collected for electricity during the 10 months ended February was £3,104 8s. 5d., an increase of £745. 1s compared with the corresponding 10 months of 1895. The cost of the supply of electric current to the High street lamps in February was £15 17s. 11d.

Tunbridge Wells—At the meeting of the Town Council it was reported that the estimate for the Lighting Committee was £200 more than the preceding half-year. Councillor Brindle said at the present time the electric light was more than paying the expense of production, and there was a slight profit towards the capital account. It only wanted an increase of consumers to ensure a contribution to the rates. When the new works got up to their full capacity he should not be surprised if the electric light undertaking yielded £1 200 to the relief of the rates, although they were so often told that it would be a burden to the rates. The Electric Lighting Committee reported that they had resolved to reject absolutely the gas-engine at the central station. A letter was received from Mr. Preece stating that Messrs. Johnson and Phillips were willing to supply a Willans engine for £750, and allow £140 in respect of the disused dynamo. It was resolved, subject to the chairman's and engineer's examination of the specification, that a Willans engine should be ordered, but that the committee were not prepared to sell the dynamo for £140. A letter was received from Dr. Gilbert claiming compensation for injury sustained by his son through the breaking of a pulley chain at the electric lighting station, and he was informed that the committee could not acknowledge any liability in the matter. It was resolved that the sum of £6. 10s. be paid annually to the Finance Committee in respect of the site of the central station. Seven tenders were received for the extension of the electric lighting station, and the committee had accepted the tender of Messrs. Strange and Son at £1,130, but as that firm wrote asking to withdraw their tender, owing to an error of £200 having been made therein, the committee recommended that the tender of Mr. J. Jarvis, at £1,356, be accepted. It was resolved that the electric lighting account do contribute £100 per annum to the relief of the rates in respect of officers' salaries not chargeable directly to the electric lighting account. Accounts amounting to £628. 12s. 4d. were recommended for payment.

Cardiff.—When the minutes of the Electric Lighting Committee came up at the County Council meeting, Mr. Good drew attention to the fact that Mr. Hallett had been appointed to report on complaints made by four fitters as to the condition of the machinery, and Mr. Good contended that the report was evasive. Mr. Melhuish was a practical fitter, and he had stated that the machinery was in a dangerous condition. His statement was confirmed by Siemens's men. He wanted to know how it happened that when the report was received on February 17 there were only seven typewritten folios, whereas on the following day, when the committee met, there was an eighth folio, which had been handwritten. That folio was not a part of the report at all. He moved that the expert's report, together with the report of the four engineers relative to the electric light machinery, be referred back to the committee for further consideration in the presence of the four engineers. There was, he added, an attempt made to shift those men from the station by other than honourable means. Mr. E. Thomas seconded the amendment, because he thought they ought to have the statements made by the fitters as well as the report of the experts. Alderman Carey ridiculed the statements of Siemens's men with regard to machinery supplied by Messrs. Davey, Paxman, and Co., who stood at the head of their trade. They were assured by the fitters, whose reports covered about 40 sheets of foolscap, that the boilers were dangerous, that there must be an accident, and that there must be loss of life. This being so, they asked one of the most experienced engineers in the town to make a report. They were careful not to engage an electrical engineer as expert because they thought he might favour the engineer at the works. No doubt, as a committee, they had made a mistake; they had engaged four fitters at 42s. a week, whereas they should have appointed three engine-drivers at 35s. and one practical fitter. Messrs. T. Morel, J. Jenkins, and Crossman spoke in the highest terms of Mr. Hallett as an engineering expert, and, on the fitters' statement being put on the table, the amendment was withdrawn, and the minutes were agreed to.

Liverpool.—A deputation from the National Telephone Company has waited on the Health Committee, and stated that the company had had under consideration the advisability of increasing the efficiency of the Liverpool service. This would mean the reconstruction of plant and the placing of the whole of the local service on what was known as the twin-wire or metallic-circuit principle. To duplicate all the existing wires of the company in Liverpool overhead would be a very serious matter, and apart from the probable interference with the service owing to the electric induction arising from the immediate contiguity of numerous wires, create a danger which might be avoided if the wires were placed underground. The directors, therefore, thought it respectful to the Corporation to place the whole matter before them, and invite their co-operation, with a view to the main routes of wires in the central parts of Liverpool being placed underground. If the Corporation consented the company would incur a very heavy expense in connection with the work—between £60,000 and £70,000—for which there would be no immediate return. In Manchester the system had been successfully adopted. The committee discussed the question, and eventually the town clerk was instructed to see what powers the Corporation possessed to deal with the highways and roads throughout the district, and to report thereon to a special meeting of the committee. The City Council propose to spend £5,500 on introducing the electric light into their chief public buildings. At the meeting of the Council Mr. R. D. Holt said he would like to see the electric light and other improvements introduced by degrees, and paid for as they went along. He objected to the policy of borrowing money and perpetually piling up debt. Mr. Petrie pointed out that in a very short time the Electric Supply Company would be taken over by the Corporation They must bear in mind that something like £3.000 per annum was spent for gas in the public buildings in Liverpool, and when they got the electric light into those buildings they would be able to effect some considerable saving. The Council's proposal was eventually agreed to. In the House of Lords on Monday the Liverpool Electric Supply Transfer Bill was read a third time and passed.

Morley.—Alderman Stockdale has been appointed chairman of the Electric Lighting Committee. The committee reported at the Council meeting that they had considered the following matters: (1) communication from the Morley Tradesmen's Society, expressing a desire of the tradesmen to have a supply of electricity; (2) an intimation from the Morley Co-operative Society that they had decided to light their premises by electricity, and had provided a place for an engine for that purpose, but if the Corporation would undertake the provision of electricity they would refrain from putting in the engine, and take the supply from the Corporation for about 500 lights; (3) the fact that various small plants were already being put up in the town for separate premises; (4) the probability that if the Corporation did not undertake the supply it would be undertaken by a private company; (5) the desirability of the matter being decided, so that mains and cables might be laid when Queen street is being repaved; and (6) the costly nature of the present supply to the town hall. The committee passed a resolution expressing the opinion that the time had now arrived when a public supply of electricity was required in the borough, and that such a supply could be profitably given. They were also of opinion that it was desirable that the ratepayers as a whole should derive any profit to be obtained from the supply, and that no private company should be allowed to obtain a monopoly or any vested interest in the matter. They therefore recommended the Corporation to proceed with the scheme recommended by Mr. Hammond, and that the town clerk at once take all necessary steps for obtaining power for the Council to proceed with the matter. Alderman Stockdale, in moving the adoption of the minutes, said the committee were very sorry indeed that the Town Hall Committee when they erected that place did not go in for "the whole hog," and he strongly urged the necessity of providing a supply for the reasons named in the minutes among others. He also gave particulars of Mr. Hammond's calculations as to the cost, etc Councillor Glover seconded the resolution, and it was supported by Councillor S. Rhodes, Councillor Scarth, and others, and passed unanimously, and the hope was expressed that the committee would take prompt action in the matter.

Imperial Tramways Company, Limited—The report of the directors of this Company, to be submitted at the general meeting to be held at the Company's offices in Bristol, states that the Dublin Southern District Tramways Company's lines being in course of reconstruction the tramways have been closed to traffic for practically the whole of the period. The directors are disappointed that they are not in a sufficiently finished state to admit of any portion of the lines being opened for public traffic at the

Digitized by Google

date of this report. There is every prospect that the lines will be ready for opening within the next few weeks. The balance of net revenue allowed of the payment of a dividend at the rate of 1 per cent. for the whole year. During the half-year, debentures for £12 500 (making up the total of £30,000) and preference shares to the amount of £50,450 have been issued to the contractors whilst the Imperial Tramways Company Limited, have accepted £30 000 ordinary shares (entitled to rank for dividend from July 1 next) in respect of their advances to that extent for the capital outlays of this company. The company are promoting a Bill in Parliament in the present session with a view to obtaining powers for considerable extensions of their electric tramways in the city and in the districts of Pembroke, Rathmines, Clontarf, and Drumcondra. The formal assents of all these four townships have been given. The whole of the projected lines can be operated from the location of the company's central power station The Bill also provides for changing the name of this company to the "Dublin Electric Tramways Company" After referring to the Middlesbrough and Reading tramways, and the Corris Railway Company, the report says the gross revenue from the four undertakings amounts to £2,499 and the net profit to £2,469. adding to which the balance brought forward (£341) a total of £2,811 is available. Of this sum £507 has been absorbed in payment of interest on debentures and temporary advances, and the directors recommend the appropriation of the remainder as follows: for preference dividend at 6 per cent. per annum £349; ordinary dividend at 1½ per cent. per aunum, £799; addition to reserve fund, £500; and to carry forward to the next account, £654 During the half-year, debentures to the amount of £4,600 have been issued, and the premiums on same added to reserve funds

Monmouth.—The Town Clerk read the following letter from the Board of Trade at the meeting of the Council in reference to the Electric Lighting Order, 1894: "Sir,—In reply to your letter of the 18th inst. on the subject of the above-mentioned order, I am directed by the Board of Trade to state that they hope to be able, in a few days, to impose regulations and to approve the system proposed to be adopted for the supply of energy under the order. I am at the same time to forward to you the enclosed description of the system of supply in the form in which the Board propose to approve it. Description of System—A high-pressure alternating-current supply at constant pressure to transformers, some of which will be placed in a sewage pumping station belonging to the undertakers, and the others singly in cast-iron pillar boxes erected in suitable positions in the streets. From the transformers a general supply will be given at a pressure of 105 volts by means of distributing mains. The power given to any single transformer will not exceed 30,000 watts. The high-pressure mains will be concentric lead covered and armoured cables adequately insulated an l laid directly in the ground. The low-pressure mains will be separately insulated cables drawn into stoneware pipes under pavements, and cast-iron pipes under the roadways. In order to provide against any accidental charging of the iron pillar boxes, their bases will be connected to the armouring of the mains and to strips of copper laid under the pavement on each side for a distance of 3ft." In reply to enquiries, the Town Clerk stated the amount proposed to be borrowed in connection with the scheme was £20,000—£11,885 for the drainage, and £8,115 for the electric lighting. Colonel Walwyn asked the Mayor whether Messrs. Bramwell and Harris, contractors for the electrical portion, were responsible to the Council for the whole scheme The Mayor said he took it that Mr. Lailey would be responsible for the drainage portion. Messrs. Bramwell and Harris were perfectly satisfied with the scheme and would take a general supervision over the whole of it. The Mayor, in reply to a question, stated that although they were asking for powers to borrow £20,000, it did not follow that the scheme would cost that amount. They wished to be prepared for all contingencies. At a special meeting of the Town Council a letter was read from the Board of Trade approving of the scheme for the installation of electric light in the borough in accordance with the Monmouth Electric Light Act, 1894

Barrow-in-Furness.—At a meeting of the County Council there was a proposal from the Gas Committee that an electric lighting sub-committee should be formed. Councillor Smith, with reference to the appointment of this sub-committee, moved as an amendment, "That the minute be not approved, as it was desirable that a separate committee should be appointed for electric lighting purposes." The reason this sub-committee had been appointed was because the Gas and Water Committee thought it necessary to take some steps so that the provisional order obtained two years ago should not be allowed to lapse and prevent any private company undertaking the work. The Chairman said according to the standing orders the Council had passed a resolution that all the provisions of the local Acts with reference to electric lighting should be managed by the Gas and Water Committee, and in face of that he doubted if Councillor Smith was in order. Councillor Smith said he was just about to point out that this was so. His amendment did not recommend the appointment of another committee, but if it were carried he would put down a notice to that effect for next month. He contended that the matter was of sufficient importance to justify the appointment of a totally separate committee. When the Council decided on the electric light, it would no doubt be in a small way, but it would soon become a large question, and the committee would have large spending powers. In the early stages of any scheme a great deal of work would have to be done, and it was important that everything should be done thoroughly, and not in any half-hearted fashion. It was also necessary, in addition to having a separate committee, that the committee should be thoroughly representative of all the wards. The electric light system when started would no doubt be in a small way, and be kept to the central part of the town; but when the works began to pay—and he believed they would before they had been long started—then they would want to extend it to other parts of the town. He had no desire to throw any obstacle in the way of the electric light, but if they were really going to go in for it, they should go about it thoroughly in order to ensure satisfactory results. The work should be in the hands of those who had faith in the movement from the very beginning, and that was the only way they could make it pay, and be a benefit to the inhabitants. If the amendment were adopted, he would next month move that a committee be appointed consisting of two members from each ward. Councillor Thompson seconded, but after a short discussion the amendment was lost.

Brighton.—At the meeting of the Town Council the following minutes of the Lighting Committee came up for adoption: "The letter from Mr. A. J. Blaber, forwarding a memorial from residents of Edburton-road and neighbourhood with reference to the lighting of the district, was again submitted. The borough surveyor presented a plan of the neighbourhood. The manager reported that the cost of laying an electricity main in Edburton-road would be £166. It was resolved that an electricity main be laid in Edburton road, and that four lamps, each fitted with a 10-c p. electric incandescent lamp, be erected in that street. A letter was read from Councillor Griffiths forwarding a memorial from residents of Upper St. James's-street, Bristol-road, and St. George's road requesting a continuation of the street electric lighting through those streets The manager presented a report as to lighting Richmond-terrace and Lewes-road, and also the omnibus route from Grafton-street to Sussex-square by arc lamps. It was resolved that 15 arc lamps be erected in Upper St James's-street, St George's-road, and Chesham-road, and that 15 arc lamps be also erected in Lewes road and Richmond-terrace. The letter from Councillor Dunk, suggesting the erection of a lamp and refuge in Queen's Park-road at the top of Islingword-road, was again submitted. The borough surveyor presented a plan showing the lighting of the neighbourhood It was resolved that the committee deem it undesirable to adopt Mr. Dunk's suggestion It was resolved that the town clerk be instructed to appeal against the assessment of the electricity works. The committee submitted accounts for the year ended December 31 in accordance with the requirements of the Board of Trade. The revenue account showed a total expenditure of £9,561 0s. 8d; the chief item being coal and other fuel, etc., £2,596; oil, waste, water, and engine-room stores, £531. 14s. 5d; wages at generating station, £1 719 4s. 11d.; repairs and maintenance £435. 5s. 4d; distribution expenses, £1.473 0s. 5d; public lamps, £569. 15s 1d; rents and taxes, £327. 0s 11d.; management expenses, £1,838. 0s. 9d.; and special charges, £70 8s. 1d The revenue was £18,575 3s 8d., comprising a balance of £1 10s. 3d. from last year £16.177. 2s 4d. derived from sales of electricity, £1,429. 19s 11d. from public lamps, and £966. 1s. 2d. from meter rents and sundries. A gross profit of £8.927. 5s. 11d. was carried forward to the net revenue account, leaving a balance of £86. 17s. 1d. to provide for bad debts. The net revenue account showed that £1,404. 1s. 9d. had been applied to local rates and £3,000 paid to reserve fund, and that after payment of interest and sinking fund appropriations, a balance of £1,150 was carried to next account. The committee resolved that the sum of £2,000 be transferred from the electricity works account to the district fund account. It was resolved to erect an additional lamp fitted with incandescent light in Edburton-road." Great satisfaction was expressed by the Council at the success of the electric light undertaking, and it was stated that the returns from private customers were £16,177, and for street-lighting only £860, which fact alone showed that the scheme was a success. Since the commencement of the business £9,330 has been paid over to the sinking fund, and the applications for lighting are increasing at the rate of 50 per cent. as compared with last year. Deputations are constantly coming to the town from places where it is proposed to establish the electric light, and it is a matter for congratulation to Mr. Wright, the borough electrical engineer, that in sixteen instances the Brighton system has been adopted. One of the last deputations was from the St. James's Vestry, their special object being to inspect the system of arc lighting in the streets, which it is proposed shall be applied for the lighting of Pall mall. Piccadilly, Regent-street, and other principal thoroughfares. They expressed great satisfaction at what they saw, and took away with them copies of the designs of the electric light standards prepared by the borough engineer and surveyor and erected in the Brighton streets.

PROVISIONAL PATENTS, 1896.

MARCH 2.

4632. Improvements in dynamo-electric generators and motors. Frederick Henry Royce and Ernest Alexander Claremont, Hulme, Manchester. (Complete specification.)

4701. Improvements in electrically and automatically actuated shooting targets or butts. Johann Neuhold, 89, Chancery-lane, London.

4709. An improved method of and electrical apparatus for automatically reducing and cutting off the steam from and thus preventing the "racing" of marine engines. Samuel Mark Folk and David Solomon Ellis, 24, Southampton-buildings, Chancery-lane, London.

Digitized by Google

MARCH 3

4748. An arc lamp for optical lanterns, stage and yacht projectors, or other purposes. Alfred John Beaumont, 6 Scarcroft-road York

4761. New or improved device for facilitating the fixing, adjustment, and removal of electric incandescent lamps. Frederic Harold Coulson, *Invention* Office, Mitre-court, Fleet street, London.

4773. Improvements in electric traction. Jean Claret and Olivier Vuilleumier, 47 Lincoln's inn fields, London

4774. Improvements in and connected with automatically operating variable resistances in electrical circuits. Cecil Burman Callow and Henry Bevis, 73, St. Stephen's-road Upton Park London.

4778. An improved method of obtaining electricity. Baz Faustino da Motta, 7 Lancaster-place, Strand, London.

4788. An improved method or process of converting the potential energy of carbon or carbonaceous materials into electrical energy. William White Jacques, 55, Chancery-lane, London. (Complete specification)

4805. Improvements in methods of and apparatus for magnetic separation. John Price Wetherill, 45 Southampton-buildings, Chancery-lane, London. (Complete specification.)

4806. Improvements in magnetic separators. John Price Wetherill, 45, Southampton buildings, Chancery-lane, London (Complete specification)

4807. Improvements in monocyclic electric generators. James Devonshire, 70, Chancery-lane, London. (Elihu Thomson United States) (Complete specification.)

4808. Improvements in safety appliances for electric brakes. James Devonshire 70, Chancery-lane, London. (William B Potter, United States.) (Complete specification.)

4817. Regulating mechanism for electric arc lamps. Erwin Lavens, 28, Southampton-buildings, Chancery-lane London. (Complete specification.)

4837. Improvements in or connected with circuit closers for electric bells. James Newton, 53, Chancery-lane, London.

4844. Improvements in electric arc lamps. Thomas Edgar Adams, 18, Buckingham-street, Strand, London. (Complete specification.)

4845. Improvements in electric arc lamps. Thomas Edgar Adams 18, Buckingham-street, Strand, London. (Complete specification.)

MARCH 4.

4864. Improvements in or in connection with electric motors, specially applicable to electric motors for tramway cars. Frank Michael Lewis, 30, Park row, Leeds.

4870. An improvements in the method of forming the electrical connection between portable electric table lamps and the current conductors. Archibald Denny and John Kempton, Leven Ship Yard, Dumbarton.

4910. Improvements in magnetic regulating and actuating mechanism. Regina Niewerth, 37 Cursitor-street, Chancery-lane London

4937. Improvements in plates, grids, or supports for the elements of secondary batteries. Edward Clark, Walter Clark, and Frank King, 47, Lincoln's inn-fields, London

4944. A new or improved electric arc lamp, carbon, and apparatus for the manufacture of the same. James Grieve Lorrain Norfolk House, Norfolk street, London. (Theodore M. Foote, United States) (Complete specification.)

4959. Improvements in electric arc lamps. Albert George Edwards and John Baker, 258, Uxbridge road, Hammersmith, London.

MARCH 5.

4964. Improvements in the brackets or supports of incandescent electric lamps. John Carter and William John Whiting, 24 Temple-row, Birmingham

4996. Improvements in jointing boxes for conduits carrying electrical conductors. Frederick Bathurst, 73 St Stephen's-road, Upton Park London

5008. An improvement in commutator brushes. William Winship Wardle, 28, Southampton-buildings, Chancery-lane, London.

5018. An improved electric bobbin or solenoid. Samuel Sidney Bromhead, 97, Newgate-street, London. (A Dorez, France.)

5023. Improvements in or relating to electric railways and tramways. Guy Carey Fricker, 46 Lincoln's inn-fields, London.

5028. Improvements in telegraphy and in apparatus therefor. Guglielmo Marconi, 24, Southampton-buildings, Chancery lane, London.

MARCH 6.

5041. Improvements in conductors for telegraphs, telephones, and electrical distribution. James Swinburne, 66, Victoria street, Westminster.

5098. Improvements in electrolytic processes and apparatus therefor. Giovanni Battista Baldo, 55, Chancery-lane, London. (Complete specification.)

5069. Improved moderating electric incandescent lamp and apparatus for that purpose. Godfrey Bamberg, 33, Barcombe-avenue, Leigham Court, Streatham-hill, London.

MARCH 7.

5168. A method of effecting electrical communication with a train and apparatus for that purpose. Alfred Charles Brown, Robert Burn, and Leonard George Tate, 28, Southampton-buildings, Chancery-lane London.

5171. Improvements in lifting and lowering gear for electric arc lamps, electroliers, and the like. Benjamin Richard Baker, 70 Chancery-lane. London (Complete specification.)

5178. Improvements in or connected with locomotives, also applicable to tramcars, electric cars, carriages, and other vehicles. Ellis Lever, 6 Lord-street Liverpool.

5191. Improvements in arranging underground electric current conductors for electric railways, and in means for making contact therewith. Arthur Petzenbürger, 31, Southampton-buildings, Chancery-lane, London. (Complete specification)

SPECIFICATIONS PUBLISHED.

1892.

9132. Heating and welding by electricity. Howard. (Second edition.)

1895.

530. Electric current reverser, etc. Tonking.

4490. Dynamo-electric machines. De Ferranti.

5058. Arc lamps. Rae.

7319. Electrical hot-plates. Fletcher and others.

9273. Electromagnets. Taylor.

10903. Electric currents. Stone and Barnes.

14485. Arc lamps Devonshire. (Harthan)

19860. Regulating electric motors Devonshire (Potter)

21381. Arc lights. Roubal.

22574. Electric insulating compositions. Grist.

22936. Electric commutators, etc. Truss.

1896.

964. Telephonic apparatus. Schwarze.

NOTES.

Convalescence.—Lord Kelvin, who has been unwell, is now, we are glad to hear, reported convalescent.

Institution of Junior Engineers.—This society will give a conversazione at the Westminster Palace Hotel on Saturday week (March 28).

Lactates.—In a communication to the German Electro-Chemical Society the use of lactates of the metals in electro-plating has been suggested by Dr. Jordis.

Fire.—Late last Saturday night the battery-room of the Crystal Palace District Electric Light Supply Company, at Beardell-street, Norwood, caught fire, and sustained serious damage. The cause of the fire is unknown.

Personal.—Mr. F. A. Newington, of the Millbank Station, London, has been appointed resident electrical engineer at Edinburgh in succession to Mr. Monkhouse, who has resigned. Mr. Newington is 32 years of age, and a native of Kent.

North-East Coast Engineers.—An invitation has been received and accepted by the North-East Coast Institution of Engineers and Shipbuilders to visit Cardiff and the Bristol Channel ports during the summer. The probable date of the visit will be the week beginning on Monday, June 22.

Concert.—The fourth annual Bohemian concert of the City of London Electric Lighting Company's staff will take place at the Cannon-street Hotel on the 31st inst. There will be an orchestra of 40 performers conducted by Mr. E. Seckington. Mr. F. Bailey is to preside, and the honorary secretary is Mr. H. Bacon, 1, Great Winchester-street, E.C.

An Accumulator Problem.—In reference to our note on this subject last week, Mr. Desmond G. FitzGerald points out that the expression as given by him for the total weight of acid was

$$A + Aq + \frac{\frac{Aq \cdot A + Aq^2}{100\,A}}{n} - (A + Aq)$$

The South African Cables.—Telegraphic communication with our South African Colonies has again been reduced to a single line. On Monday a notice was issued by the Eastern Telegraph Company that the Aden-Zanzibar cable was interrupted, thus cutting off communication with East and South Africa by the East Coast route, and leaving all messages for South and East Africa to go by the West Coast line.

Institution of Electrical Engineers.—By permission of Mr. Frank Bailey, arrangements have been made for a party of students to visit the Amberley-road, Manchester-square, and Sardinia-street central stations of the Metropolitan Electric Supply Company on Saturday, the 28th inst. The party is to meet at Amberley-road at 3.30 p.m., and students desiring to be included in it should write to Mr. G. C. Allingham, Eldon House, Lyndhurst-road, Hampstead, N.W.

The Junior Engineers.—In the course of his paper on "Coal Handling for Steam Generation," read before the Institution of Junior Engineers, Mr. C. H. Fletcher remarked that the subject had received but little attention at the hands of English engineers, but owing mainly to the exertions of Mr. C. W. Hunt, of New York, its importance had been fully recognised in the United States, where many applications of special plants had been installed. Descriptions were given of appliances used for hoisting, carrying, and delivering the coal consumed in the generation of steam at various large power and locomotive coaling stations.

Royal Meteorological Society.—At the meeting of the Meteorological Society on Wednesday last, Mr. E. Mawley (president) in the chair, Mr. Frederic Gaster, F.R.Met.Soc., of the Meteorological Office, delivered a lecture on "Weather Forecasts and Stormy Warnings, how they are prepared and made known." The necessity of the isolated observer knowing the condition of the barometer at other places in order to make a reliable forecast was enforced, and the system by which the Meteorological Office obtained this information by the telegraphing of simultaneous observations was described.

Transfer of the Telephones.—It has been very generally stated that the Post Office authorities will take over the working of all the telephone trunk wires of the National Telephone Company on April 4. According to the *Standard*, however, this is not quite accurate, except as indicating the beginning of the process. The Post Office on that day will take over the trunk lines only in the South of England, or, roughly speaking, the district south of the Thames from Kent to Cornwall. The intention is to proceed gradually, taking over other districts in succession, but it is hoped that the whole transfer will be completed in the course of a few months.

Midland Mining Engineers.—At a meeting of the Midland Institute of Mining Engineers at Leeds, a paper was read by Mr. H. Wormald on "Adjustable Piston Rings," in which he described a system of adjustment invented by himself. In practice, he said, piston rings did not move out as desired or theoretically allowed for. Some system of adjustment was required to make them fit the body of the cylinder, and this he claimed to have obtained by his system of packing rings, which formed one solid block after setting in position. He quoted some cases in which the ordinary style of piston had been replaced by the Wormald piston with extremely good results. A discussion followed.

Royal Institution.—The lecture arrangements after Easter at the Royal Institution include three lectures by Mr. C. Vernon Boys on "Ripples in Air and on Water"; Prof. T. G. Bonney will give two lectures on "The Building and Sculpture of Western Europe" (the Tyndall lectures); Prof. Dewar, three lectures on "Recent Chemical Progress"; and Mr. W. Gowland, three lectures on "The Art of Working Metals in Japan." The Friday evening meetings will be resumed on April 17, when a discourse will be given by M. G. Lippmann on "Colour Photography." Succeeding discourses will probably be given by Prof. G. V. Poore, Colonel H. Watkin, C.B., Prof. Silvanus P. Thompson, Prof. J. A. Ewing, Prof. J. A. Fleming, and other gentlemen.

Proposed Pacific Cable.—The *Daily Chronicle* says, apparently on the best authority, that the Pacific Cable Conference, which is to meet at the Colonial Office directly after the Easter recess, is looked forward to with the keenest interest in Canada and Australia. The two Agents-General who are to represent Australasia are now awaiting their instructions from the Colonial Governments, and the Canadian delegates—Sir Mackenzie Bowell, the Canadian Premier, and Mr Sandford Fleming—will bring their instructions with them from Ottawa. It is understood that definite tenders will be before the conference, and the chief business will therefore be to decide, not the feasibility of the cable or its cost, but the allocation of the costs between the Colonies and the mother country, and whether it shall be a State cable or a company undertaking. There is undoubtedly a strong Colonial feeling in favour of an all-British cable, both to Australasia and later on to South Africa, and the Colonies seem ready to pay their share of the cost

Digitized by Google

The Telephone Monopoly.—A meeting of subscribers to the Tunbridge Wells telephone exchange has been held to discuss their grievances against the National Telephone Company and the steps to remedy them. It appears that the Post Office have declined to establish an exchange at Tunbridge Wells, so that although there is great dissatisfaction with the service provided and the charge made by the National Telephone Company, there is practically no available remedy. Moreover, even were the Post Office to establish an exchange it is considered that their charges under the present scale would be prohibitive. A circular has therefore been issued by a committee of the subscribers with a view to raising the funds and obtaining the support necessary for taking definite and concerted action on the subject, and it is stated that the circular has met with a satisfactory response in this respect. The committee have also been in communication with the United Kingdom Telephone Defence Association with a view to mutual assistance.

Water Power.—The question of the advantages of utilising water power by means of electric transmission of energy is one that is being constantly discussed. On the face of it, this would seem the proper thing to be done always and everywhere. When, however, it comes to practice, the apparent promise frequently exceeds the performance. This is not the fault of the electrical part of the work, but usually arises from the inherent defects of a water-power supply. It is so seldom possible to get it anything like constant, particularly when it takes the at first sight fascinating form of a mountain stream with a good fall. Switzerland is a country of mountain streams and dear coal, and consequently has gone in for water-power installations. Yet, if we may trust the results given by Mr. Jenny, except for very small installations, or where the power has not to be taken more than three miles, these do not work out cheaper than would similar installations run with a steam-engine in a country where coal is obtainable at a reasonably low rate.

Trunk-Line Telephones.—The completion of the trunk-line telephone from London to Portsmouth was inaugurated last Friday by a conversation of a congratulatory character between the Lord Mayor of London and the Mayor of Portsmouth. The latter sent his congratulations, and expressed a hope that large benefits would accrue from the use of the wires. The Lord Mayor replied that he trusted that the telephonic communication between so important a town as Portsmouth and the City of London would be productive of much commercial benefit to each. Lord Harris, vice-president of the National Telephone Company, on behalf of the directors of the company, expressed the gratification felt at putting the Mayor of Portsmouth in communication with London. Their object was to establish speedier communication throughout the country with the utmost possible celerity. The Mayor of Portsmouth replied in suitable terms. Nothing could well be nicer—and yet there are people who complain of the service and charges of the National Telephone Company and of the system which gives it a virtual monopoly.

Electro-Harmonic Society.—The following is the programme of the smoking concert to be given by this society on Friday next, March 27, at the St. James's Hall Restaurant: Part I.: overture, "Mirella" (Gounod), the Orchestra; old Scotch song, "O, she's bonnie," Mr. Arthur Thompson; recitation, "The Taking of Lungtung Pass" (Kipling), Mr. Tammadge; vocal tarantelle, "La Danza" (Rossini), Mr. William Webster; violin solo, "Scotch Airs," Mr. T. E. Gatehouse; humorous selection, Mr. Harry Hudson; entr'acte, "Loin du Bal" (Gillet), the Orchestra. Part II.: piano and violin, "Tempo di minuetto" and "Allegro Vivace," from Sonata in G major, Op. 8 (Beethoven), Messrs. Izard and Gatehouse; Arabian love song, "Medjé" (Gounod), Mr. Arthur Thompson; piano solo, "Andante and Rondo Capriccioso" (Mendelssohn), Mr. Alfred E. Izard; recitation, "Der Dale off a Tog" (Sapte), Mr. Tammadge; songs, "The Irish Reel" and "The Donovans" (Alicia A. Needham), Mr. William Webster; violin solo, "Romance and Tarantelle" (B. Tours), Mr. T. E. Gatehouse; humorous selection, Mr. Harry Hudson; march, "Fest" (Raff), the Orchestra. The musical directors are Mr. T. E. Gatehouse and A. E. Izard.

Horseless Carriages.—A motorcart has been running about the streets of Maidstone, and has somewhat disturbed the Town Council. One councillor expressed his opinion that it was disgraceful that "it should be allowed to run about as it does," while another remarked that it would be difficult to "take the machine up," but it ought to be stopped running about the town, as "it was not only against the local laws, but also against an Imperial Act of Parliament." The Mayor said he did not know whether he was to blame for this or not. He gave permission for the carriage last week to be driven to the Athletic Ground on the day of the exhibition. He saw the chief constable in the matter, and several towns were written to with the idea of knowing what the general practice was, and it was agreed that so long as there were no complaints in Maidstone it should be allowed. It seemed hard that they should object to the carriage running in Maidstone when the law would soon allow them to run. Ultimately it was agreed that the Mayor should tell the owners of the motorcart that they must not run it about any more just for the present. At any rate, that is a more civil way of doing business than sending a summons, and probably quite as effective.

Spanish Cables.—Mr. Angel Guerra continues in *El Telegrafista Español* his advocacy of a Spanish Transatlantic line, and incidentally urges the advantages of several minor connecting links in the Spanish system. Above all, he points out the desirability of the Government having a contract with some of the companies possessing repairing ships, so that one of these would be at once available in case of any breakdown. In this way would be avoided what happened in the case of the interruptions of the Canaries cable, when all the energy and good will of the Department was unable to prevent the loss of a month or more in obtaining the authorisation of the credit necessary for the repair of the cable, not to mention the poor appearance made only recently in the case of the Tarifa and Tangiers cable left for months broken and abandoned to the mercy of the currents of the straits. With every possible sympathy with the desire of the Spaniards for a good and well-worked cable service, this is unfortunately rather a bad time for urging the undertaking of much new work. The Spanish Government has at present not too much either of credit or cash to spare, and on what it has the Cuban trouble will have a first claim. It is not probable, therefore, that we shall see Mr. Guerra's cable laid yet awhile.

The Love Tramway System.—The conduit system of electric traction worked out by Mr. Love has been recommended as a convenient one to adopt in cases where it is necessary to change from an overhead to an underground system, as, for instance, in the case of a line starting in the country and ending in a town, where the posts and overhead wires of a trolley system are not desirable. Shortly described, the system consists in replacing the overhead trolley by a pendant bar similar to a cable grip bar, carried below the car and working through a slot in

Digitized by Google

the top of a conduit in the centre of the tramway track. This pendant bar carries at its lower end a double trolley with wheel rolling contacts or with sliding contacts, which press upwards against copper conductors carried on insulators in the conduit, which is similar in all essential respects to a cable tramway conduit. With this system the tramcar is the same as that which is used with the overhead trolley and overhead wires. The electrical motors are the same, the starting and controlling apparatus for the car is the same, and as a fact the same cars are used where the Love conduit system is laid as are used with the overhead trolleys and wires. A line at Washington has in its length both the overhead and underground systems, the cars on every journey working perfectly on both sections.

Discharge Through Gases.—Recently Mr. Lehmann summarised in the *Zeitschrift für Elektrochemie* a number of papers, chiefly from *Wiedemann's Annalen*, on the subject of the passage of electricity through gases. The view sometimes accepted is that the process of discharge is not, like electrolytic conductivity, dependent on the presence of ponderable atoms, but is a particular mode of motion of the ether filling the spaces between the atoms, which motion would take place much more freely and completely in pure ether free from atoms than in gases. Mr. Lehmann, however, adopts the theory of Faraday, which assumes a breaking down of the molecules as a result of high voltage. The disruptive discharge takes place only when the difference of potential in the gases has reached a certain value, and it is always confined to a sharply defined limit. It is not a part of a closed conducting circuit, but part of a so-called open circuit which is completed through a dielectric. The voltage between the electrodes is nearly independent of the current strength, and Ohm's law therefore does not apply. Again, the heat of the current is not proportional to the square but to the first power of the current, and therefore Joule's law does not apply. The conclusion is arrived at that the discharge is not continuous, and that Faraday's hypothesis is up to now the one which agrees most satisfactorily with observed phenomenon.

Rontgen Radiations.—The subject of the new radiations continues to occupy a space in the *Proceedings* of societies and the pages of the American and Continental technical Press which seems somewhat out of proportion to the results obtained. In reference to Mr. Le Bon's *lumière noire* experiment, it has been discovered that no Röntgen effect is produced with any amount of exposure unless the light is passed through ordinary glass. Uranium glass does better, so that the effect has some connection with the production of fluorescence, and there are no Röntgen rays at all in pure sunlight. In England the subject has been debated at the Physical Society, and the result of the proceedings at the Royal Society, particularly Lord Blythsword's experiments on the subject of reflection, will be awaited with interest. One result of the new photography has been to revive experiments of the type in which a coin or other metallic object is placed on a sensitised plate, and so connected up that the plate forms the break in an open circuit. On development an image is obtained of the coin. The *Western Electrician* has devoted a page and a half and a quantity of very pretty illustrations to work of this kind. The plate is, of course, so sensitive as to be easily affected even when there is no visible or measurable discharge, and there is no necessity to assume any Röntgen effect. When a spark actually passes, the result is very interesting.

The National Telephone Company.—At the third annual dinner of the staff of the National Telephone Company at the Holborn Restaurant, the chair was taken by Mr. W. E. L. Gaine (general manager), and among those present were Lord Harris (vice-president), Sir Albert Rollit, M.P., Mr. W. C. Quilter, M.P., Sir Robert Hunter, Prof. D. E. Hughes, Mr. W. H. Preece, Mr. H. C. Fischer, Mr. Albert Anns, Mr. F. Crisp, Mr. J. Hookey, Mr. H. E. Clare (town clerk of Liverpool), Mr. G. Tucker, Mr. R. E. Fox (town clerk of Blackburn), and Mr. Chetwynd. The Chairman, in proposing "Success to the National Telephone Company," said that during the past year they had increased their *clientèle* by nearly 9,000. They had opened 50 more exchanges, and were now sending telephone messages through the kingdom at the rate of 313,000,000 per annum. In future the activity of the company would be confined to the local requirements of the large towns, and it rested with the local authorities to furnish proper facilities to enable the company to carry on the service on the most efficient modern principles. On April 4 the trunk lines would become the property of the State, and he could assure the officials of the Post Office that the officials of the company would give them the most cordial and loyal support. He hoped the State would look carefully after their own branch, and not be too anxious to enter on that part of the business which appertained to the junior partner. The very essence of such a service as theirs was that it should be a monopoly in not more than two hands, and it was in the public interest, he believed, that the local service should be in the hands of the company rather than of the State.

A Tea Factory Plant.—In the course of an article on the use of electricity as a motive power in tea factories, the *Ceylon Observer* says the question of the transmission of electrical energy for use as motive power is one fraught with much interest for Ceylon, particularly in districts where water power is easily available. A short description is then given of a scheme which has been undertaken by Messrs. Bousted Bros. to drive the machinery in the factory of Mattakelle estate. It is proposed to erect an 80-h.p turbine on the Kotmalaeganga, which, in turn, drives a dynamo capable of generating a strong current. The current is to be carried to the factory by means of an overhead cable guarded at public places by a net suspended underneath. In the factory will be installed an electrical motor of the three-phase high-tension type. The site on which it is proposed to erect the turbine is on Lindula estate, and negotiations for securing it are in progress. It is probable that should an electrical station be established at this point electrical energy will also be supplied to Lindula. Of the financial success of the installation our contemporary is sanguine. The first cost no doubt is heavy, but if against that is reckoned the cost of firewood, now getting a scarce commodity in the district, the superintendence involved by the use of a steam-engine, and the cost of upkeep involved by the latter, it is found that a considerable saving will be effected. It is considered that the motor will require little or no looking after beyond what a coolie is able to give. This is the first venture of its kind in Ceylon, and, so far as transmitting electricity for motive power is concerned, is probably the largest in the East Indies.

Germany. — In the *Elektrotechnische Zeitschrift* for March 5 are given statistics of the number and character of the electric supply works in the German empire for 1895. In the briefest tabular form these cover six of our contemporary's exceedingly large pages. A total of 180 stations are enumerated, with an aggregate output of 40,471 kilowatts. Of these 139, giving 35,166 kilowatts, are direct-current plants. Alternating-current stations number 16, with an output of 4,396 kilowatts, and the three-phase system counts 12, with 4,468 kilowatts. Four works, with

Digitized by Google

1,746 kilowatts, are mixed tri-phase and direct; while there are two classed as mixed alternating and direct, with a joint output of 115 kilowatts. Compared with the numbers of the previous year, there is a gain of 19 direct-current plants, and only one simple alternating. Of the tri-phase plants four are new, and the tri-phase and direct have not only increased from two to four, but the kilowatts have risen from 646 to 1,746. On the other hand, there seems to be one less combined alternating and direct than in the previous year. It may be added that in 102 of the direct-current plants accumulators are used. With reference to the source of power, steam heads the list with 99 plants. Counting by number only, water power makes a good show with 41, especially when 19 water-power stations which have steam-power plant only as a reserve are added. The aggregate kilowatts, however, of these are only 4,224 and 2,280 respectively, so that reckoned in this way the proportion comes out very differently. With regard to the magnitude of the stations, eight are over 1,000 kilowatts and 20 over 500 kilowatts. The annual increase in the number of stations since 1888 appears to have been about 20, but it is stated that there are now 82 either about to be commenced building or definitely decided on.

Lighting Jute Mills.—In a report on the hours of working in jute mills in Bengal which has been made by Sir John Leng, M.P., to the *Dundee Advertiser*, mention is made of the use of the electric light to enable the work to be done in shifts. Whereas in Dundee working in shifts is unknown, the method of working in the Indian mills has long been different. The habits of the natives, consequent on the great heat during nine months of the year, their weaker constitutions, the distance in some cases of their dwellings, and their love of bathing, led them to prefer working in what may be described as alternating shifts, so that they might work at two different parts of the day with a pretty long interval between. Until recently the engines started at daylight in the morning and ran till sunset—about half-past five in winter and seven in summer. Artificial lighting by either oil or gas would have been considered objectionable on account alike of the risks of fire, the fumes, and the heat. The idea occurred to Messrs. Birkmyre, the proprietors of the Hastings Mill, that by running night and day, with the electric light, they could double, or nearly double, the production from the same machinery. The idea of using the electric light by them was not carried out until it was known that it had been satisfactorily introduced in several Dundee mills. Others then resolved to try it in their mills in order to secure a more uniform day of working hours. There are still a number of the older and larger mills that have not adopted the electric light, believing that the old-fashioned system of working from sunrise to sunset is more profitable. The mills at present using the electric light are the Howrah, Gourepore, Ganges, Seebpore, Fort Gloster, Samnuggur, Titaghur, and Victoria, the majority of which during the winter months run 14 hours a day, but the last three stop at half-past two on Saturdays.

Acetylene.—Mr. J. C. McMynn, in the course of a paper read before the North-Western Electrical Association at Milwaukee on the use of acetylene, sums up the situation from the standpoint of the American electrical supply companies. Acetylene, he says, has an illuminating power much greater than common gas. No investment for street mains is necessary, hence the gas companies must use it either as an enricher or as an adjunct to their present system to supply isolated buildings and residences, which can be reached neither by their present mains nor by electric lights. If they obtain the rights for using acetylene, they will have a weapon which will be as much stronger than the Welsbach burner as the acetylene flame is stronger than the Welsbach light. To produce this gas or calcium carbide, the gas companies must put in electric plants, which, when not in use making carbide, can be placed in competition in electric lighting. There are places, and many of them, where nothing will ever supersede the use of electric lights, but when it is considered that only 5 per cent. of the residents of Southern Wisconsin are reached by gas and only 30 per cent. are reached in Milwaukee, and that even less are supplied with electric light, there is a field opened which is wonderful in the possibilities for successful investments and large business. Most lighting plants are idle during at least half the time, and could by manufacturing calcium carbide be made producing plants for the whole time, and could thus reach a territory which cannot be reached by either the gas or electric supply companies. As for cost, since one-third cubic foot of acetylene gas burned per hour gives more illumination than a 16-c.p. incandescent light or five cubic feet of ordinary gas, Mr. McMynn estimates that acetylene will work out very much more cheaply than either incandescent gas or electric lighting.

Bimetallic Wire.—The New York *Electrical Engineer* says the high conductivity of copper has made that metal an essential for heavy current transmission, while the telegraph and telephone services have long since adopted and are constantly increasing their use of it. But, unfortunately, the high conductivity of copper is accompanied by low tensile strength as compared with iron or steel, and the latter, on the other hand, are of low conductivity. In overhead work in America copper wires of large diameters are frequently employed to secure increased tensile strength, and even then the results sought are not obtained. As is well known, copper stretches under its own weight, and unless the slack is taken up at once innumerable line troubles appear. Having wires of large diameters to carry, it follows that large poles are required, and as copper will not permit of great spans, the poles must be placed close together. The tension on the poles is very great, bracing and guying an absolute necessity, all of which adds to the cost of the line. Copper will not corrode like iron: it is a splendid conductor of electricity, but is lacking in mechanical strength. To combine both electrical conductivity and mechanical strength it was some time ago proposed to construct a compound wire, consisting of a steel core with copper shell. Wires of this type have been made, and an example of their use are a pair of lines of the Postal Telegraph Company between New York and Chicago. The lines were erected over 10 years ago, and are still in use, with excellent results. These wires were made by depositing copper electrolytically on the steel core, but the cost involved was such that the product was too high-priced for general use. The subject, however, has again been taken up, and a bimetallic wire which has been made the subject of an American patent is to be placed upon the market. It is considered that the new wire may possibly come in useful in tramway work on the overhead system.

Electric Transportation.—The New York *Electrical Engineer* contains a short article—apparently intended to be the first of a series—by Mr. W. Baxter, jun., on the possibility of supplanting the steam locomotive on trunk railways by some means of electric traction. The rapidity with which the electric motor has invaded the street railway field in America naturally created a very general belief that it will not be long before it will enter the domain of the steam locomotive and repeat on a larger

Digitized by Google

scale its extraordinary successes of the past. The general run of men who base their opinions wholly upon what they see and have no technical knowledge by which to be guided, take it for granted that if electric motors can propel small cars with so much success as to replace horses and cables, that there is no reason why they should not be able to do equally as well with larger carriages. Moreover, the majority of semi-informed engineers who believe that it is always wise to boom new engineering developments were not slow in coming to the front with the most positive assertions to the effect that the locomotive was doomed to oblivion and would only be known as a museum curiosity by the end of the century. One electrician when interviewed on the subject said: "Electricity will displace steam if economy, as well as speed and safety, is a factor of locomotion, not because it will make easily a speed of 100 miles an hour while steam strains itself to make 60, but because it will get 1 h.p. out of from 1lb. to 2lb. of cheap coal, while out of 6lb. of dear coal a locomotive engine can only get that same 1 h.p. It will displace it because it will be cheaper." Now, as a matter of fact, if electricity is to depend wholly upon the difference in coal consumption between locomotives and large triple-expansion stationary engines to obtain a foothold on trunk line railways, it may as well give up the contest at once. Not because the difference in coal consumption is not as great as has been claimed, but because the total cost of fuel forms but a small percentage of the cost of operating a railway system; therefore, even if the entire amount were saved the reduction in running expenses would not be so great as to enable electricity to revolutionise present methods. Mr. Baxter, however, believes that if the advantages of electric traction are put forward in a fair and impartial manner, a claim of superiority can be maintained.

New Rontgen Tube.—It will be remembered that it has been discussed whether glass is altogether the best material to use in the manufacture of vacuum tubes for the purposes of Röntgen ray photography, and whether it would not be advisable to follow out Prof. Lenard's original idea of using aluminium instead. Prof. Lenard's form of tube is somewhat difficult to construct, but a form of "ray lamp" described in the *Electrical World* appears to present fewer mechanical difficulties, and it is stated has been used with satisfactory results. The new tube—neither lamp nor tube seems quite the proper word, but a new one has yet to be devised—is the invention of Prof. Woodward, of Harvard University. It is conical in shape, and its characteristic difference from the ordinary Crookes tube is that the side or wall of the lamp—*i.e.*, the curved surface—is made of sheet aluminum, $\frac{1}{10}$in. in thickness; the base of the lamp is of solid glass, practically a plug fitted into the base of the aluminum cone with plaster of Paris, and made airtight. A metallic ring passes around the base of the cone, and holds the sides of the cone firmly to the glass bottom. Through a point a little to the side of the centre of the glass base passes the cathode pole into the lamp, and at the end of this is fastened a platinum disc, at such an angle as to be parallel with one position of the generatrix of the cone. The cathode discharge is thus thrown on one part of the cone and not on the vertex. As aluminium is a conductor the anode might be anywhere, but it is put, as a matter of fact, at the top. At the vertex there is also a glass tube with a stopcock. This glass tube is fastened in with plaster of Paris and bound by a metallic ring. A circular wooden disc is fastened on the inside of the metallic cone, to prevent any collapse of the sides on exhaustion. By this construction it has been found that the difficulty from the absorptive power of the rays by the glass of the Crookes tube has been eliminated in a most marked degree. Mr. Woodward has worked with this lamp with induced currents of between 25,000 to 30,000 volts, and with these very clearly defined radiographs of the hand have been taken in five seconds. So far as we can see, the only weak part of the "lamp" is at the vertex of the cone. At any rate, its successful use shows that the phosphorescence of glass is not necessary for the Röntgen effect. But that was also a consequence of the original experiment of Prof. Lenard, which ought to have led to the discovery of the new photography more than a year ago—and did not.

The New Photography.—As we anticipated on its first discovery, the application of the new photography to surgical purposes has not been long in coming to the front. It is no longer possible even to note the accounts of the work done in this direction, and this, and the results attained, must be left to the medical Press. It may, however, be mentioned that investigations by means of the Röntgen radiations are no longer confined to parts of no great thickness, like the hands and feet. Indeed, Mr. A. F. Stanley Kent, of St. Thomas's Hospital, London, has succeeded in transmitting the X rays completely through the body, so that the most deeply-seated viscera become visible, and the condition of such organs as the kidneys can be investigated. The photographs which have been so far taken show internally those portions of the body lying between the fifth rib down to the pelvis, and there are distinctly visible in these photographs the bone of the pelvis, the spinal column, and the lower ribs. The space occupied by the kidney is slightly more transparent in the negatives, thus indicating that the kidney itself is rather more opaque than the surrounding tissues. In this connection there at once arises the question whether it is possible in this way to diagnose the presence of renal calculi. As there seemed to be some doubt as to the opacity of the calculi, Mr. Stanley Kent took photographs with a view to clear up that point. It was found that although there is a considerable difference in the relative transparency of different stones, all of them are sufficiently opaque to render it possible to differentiate them clearly from the surrounding tissues. Somewhat similar experiments have been made by Dr. Hall-Edwards at Birmingham. As in work of this kind the use of the cryptoscope, at any rate, as a preliminary before taking photographs, would be probably desirable, it may be well to note that, according to a communication made by Mr. Herbert Jackson at the Chemical Society, the best fluorescing material to use for the disc is potassium platinicyanide. Mr. Jackson tried many other platinicyanides, besides a number of platosamine salts, but the potassium salt gave by far the best results. If, however, the use of the Röntgen rays in medical work is to become a regular practice, the next thing to be settled is who is to do the work—the doctor or the electrician. It is obvious that the general practitioner cannot use the Röntgen apparatus as he uses a stethescope, and though some of the hospitals have set up apparatus for experimental purposes, progress in this direction is necessarily limited by the fact that all medical men are not skilled electricians. On the other hand, the field has been taken by the electrical engineer. Mr. A. A. Campbell Swinton, who was one of the first to show the Röntgen photographs in this country, has arranged to establish a laboratory for this purpose at 66, Victoria-street, and the Electrical Standardising Institution has announced that patients, accompanied by their medical attendant, can be examined in this manner at Faraday House, Charing Cross-road. Others will doubtless follow.

THE MECHANICAL EQUIVALENT OF HEAT.

BY A. H. ALLEN.

In the course of an article headed "City and Guilds of London Institute," which appeared in your issue of the 14th ult., the writer, discussing heat units and measurements, takes occasion to criticise the value used by Prof. Ayrton—1,400 foot-pounds—for the mechanical equivalent of the heat required to raise 1lb. of water 1deg. C.

This value has doubtless been taken from p. 201 of Prof. Ayrton's "Practical Electricity," which was published in 1886; it must, therefore, in the first instance be judged with due regard to the state of our knowledge of the subject at that date; and as the value of "J" is a matter of immediate interest to engineers, both electrical and mechanical, it will perhaps be well to review the question briefly.

Since the famous experiments of Joule in 1850, which gave the first close approximation to the value of the constant, many experimenters have investigated the problem, and all but one have obtained a higher value than that given by Joule. The principal results published prior to the year 1886 are tabulated below:

Date.	Observer.	Value of J.
1867	Joule	1,389·6
1870	Violle	1,427·7
1875	Puluj	1,397·6
1878	Joule	1,390·9
1878	Weber	1,386·2
1879	Rowland	1,400·9
	Mean	1,398·8

It is clear that in 1886 the exact value of J was not known within 1 per cent., and that the error caused by Prof. Ayrton's employing the number 1,400 was less than 0·1 per cent. above the mean of all results.

These results are not, however, all of the same weight; many of them are unreliable on account of defects in the apparatus used, or in the methods of research adopted. Therefore it is important to consider the accurate determinations which have been made since 1886, for these have greatly reduced the magnitude of the probable error, and have made it possible to arrive at a value for J which is certainly not far from the truth.

The whole question is summarised by Mr. E. H. Griffiths (himself a practical authority on this subject), in a paper on "The Thermal Unit," which was read at the last meeting of the British Association (Ipswich, 1895), and printed in the *Philosophical Magazine* for November, 1895. Mr. Griffiths there discusses at length the data bearing upon the question, and selects the following results as being the most worthy of consideration:

Date.	Observer.	Value of J.
1878	Joule (corrected)	1,395·8
1879	Rowland	1,400·9
1892	Miculesen	1,398·3
1892	Griffiths	1,404·0
1894	Schuster and Gannon	1,402·9
	Mean	1,400·4

Of these results, Rowland's carries the greatest weight; and Mr. Griffiths concludes that the value of J may be taken as $41{\cdot}89 \times 10^6$ ergs—*i.e.*, 1,400·9 foot-pounds, with a probable error of less than 1 in 800, the standard heat unit being defined as the gramme-degree at 15deg. C. We may, therefore, safely follow Prof. Ayrton's example of 1886 by using the number 1,400 for all practical purposes, since this differs from Rowland's result by less than 1 in 1,500, and is, therefore, well within the limits of the probable error in the latter.

The value of J in terms of the Fahrenheit scale is $\frac{5}{9} \times 1{,}400{\cdot}9$, or 778·2 foot-pounds—say, 778 in practice. Approximately the same conclusion was reached in a paper by Prof. Ayrton and Mr. Haycraft on a "Students' Simple Apparatus for Determining the Mechanical Equivalent of Heat," which was published in the *Phil. Mag.* for February, 1895; and the mean of a series of experiments recently made by a group of junior students at the Central Technical College with the same apparatus gave 1,405 for the value of J, which is less than 0·3 per cent. above the more correct value, though, of course, it cannot compare in accuracy with the results given above.

The chief difficulty that remains in the way of a more accurate determination of the equivalent is the uncertainty as to the specific heat of water at different temperatures. The temperature at which the gramme-degree is to be regarded as the standard heat unit has never been agreed upon; the calorie is vaguely defined to be "that quantity of heat which is required to raise the temperature of one gramme of water one degree Centigrade"; but whether the "one degree" is to be from 0deg. to 1deg., 14deg. to 15deg., or over any other definite range of temperature, has not been decided.

As the specific heat of water is not constant, but is a function of the temperature, the value of the calorie—and of the pound-degree—depends upon the temperature at which it is taken; this would matter little if the function referred to were known, but the difficulties in the way of accurately determining its value are of such magnitude that no closely concordant results have yet been obtained. For practical purposes, however, the difference due to this cause is inappreciable, and the value of J given above is well within the limits of accuracy attainable in all ordinary measurements.

In the same article which raised this question it is stated that "Heat generated = $0{\cdot}0315\ C^2 \times R \times t$ heat units." The writer omits to mention that the time, t, is here to be measured in *minutes*, not *seconds*, as it was in the preceding formulæ; and lower down in the formula which should read

$$[\text{Foot-pounds} =]\ 44{\cdot}25 \times C^2\ R\ t,$$

he omits the t altogether. It is not, however, omitted in this formula as given in "Practical Electricity."

The constant 0·24 used in the formula

$$\text{Heat units} = 0{\cdot}24\ C^2\ R\ t$$

should be altered to 0·239 to correspond with the corrected value of J within 0·12 per cent.

In conclusion, it is highly desirable that the value of J given above, which is already well established in use in all scientific work, should be adopted by practical engineers also; and, as in the case of the purely electrical units, this end would probably be most quickly attained by the intervention of the Board of Trade, or some other influential authority, such as the Institution of Civil Engineers. The question is one of great importance, and delay only adds to the difficulty of setting it at rest.

THE ROUEN ELECTRIC TRAMWAYS.

Electric cars have been running over the greater part of the Rouen tramway system for the past two months, but the actual inauguration—intended to mark the completion of the whole network for public service—is announced to take place on Sunday next, the 22nd inst., when a large number of invited guests will assemble for a public inspection of the more important lines, the power-house, etc., meeting afterwards at a dinner in the new buildings intended for the Rouen National Exhibition to be opened this spring.

It will, therefore, not be out of place to publish some particulars of the Rouen lines, more especially as they represent the largest network so far equipped for electric traction in France, and indeed in the whole of the Continent excepting Hamburg.

The total length of lines built and authorised in Rouen for the use of electric traction is approximately 40 kilometres, equal to, say, 25 miles of single track. Practically the whole of this distance is now equipped and operated with electric cars, the only exception being a short length of line from the cathedral to the Place Beauvoisine through the central (and older) part of the town, where the streets are extremely narrow (in several places the roadway not exceeding 13ft. in width): and also an extension of the Sotteville line to Quatre Mares, at present worked by horse cars on a half-hour service, the traffic being very small.

There are in all 10 distinct services or lines operated as follows.

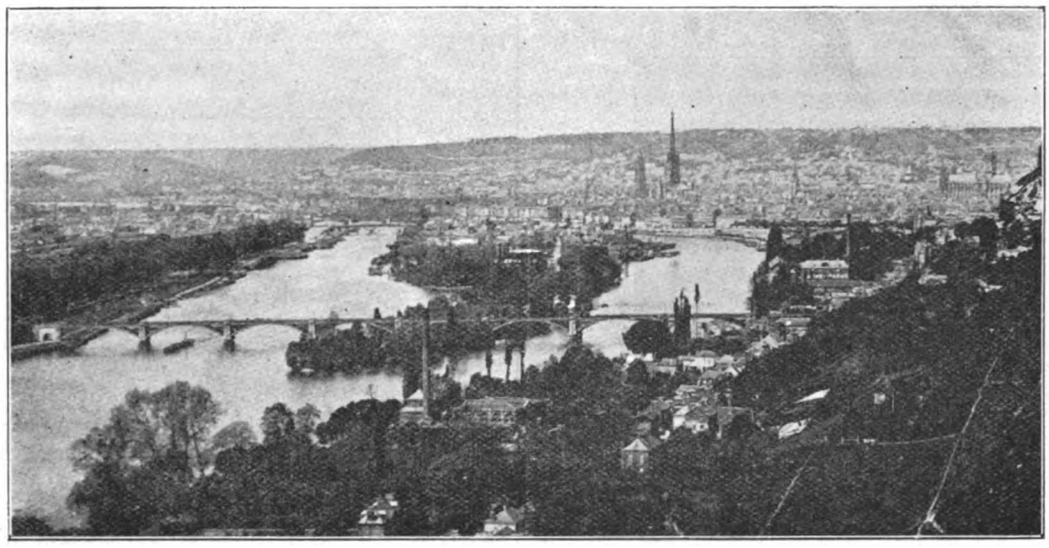
Digitized by Google

1. Pont Corneille to Maromme.
2. Quai du Mont Riboudet to Darnetal, *vid* Hotel de Ville.
3. Pont Corneille and Orleans Railway Station to Rue Verte Railway Station and Champ des Oiseaux.
4. Cathedrale to Place des Chartreux.
5. Circular line round the Boulevards and Quais.
6. Hotel de Ville to Northern Railway Station.
7. Hotel de Ville to Sotteville.
8. Extension to Quatre Mares.
9. Hotel de Ville to Petit Quevilly.
10. Place Beauvoisine to Jardin des Plantes.

between the paving setts and rails. The only cross-ties employed are of bar iron riveted to angle-pieces bolted to the rails at intervals of 9ft. or so. Chicago bonds are employed throughout at the rail joints, etc., in duplicate, and for the long bonds at junctions, etc., the same are used cut in the middle, and a splice of ordinary tinned-copper wire of equal gauge (No. 00) put in with carefully soldered joints.

Cross bonds are inserted at every fourth rail joint, and where double track is found, the two tracks are also cross-connected.

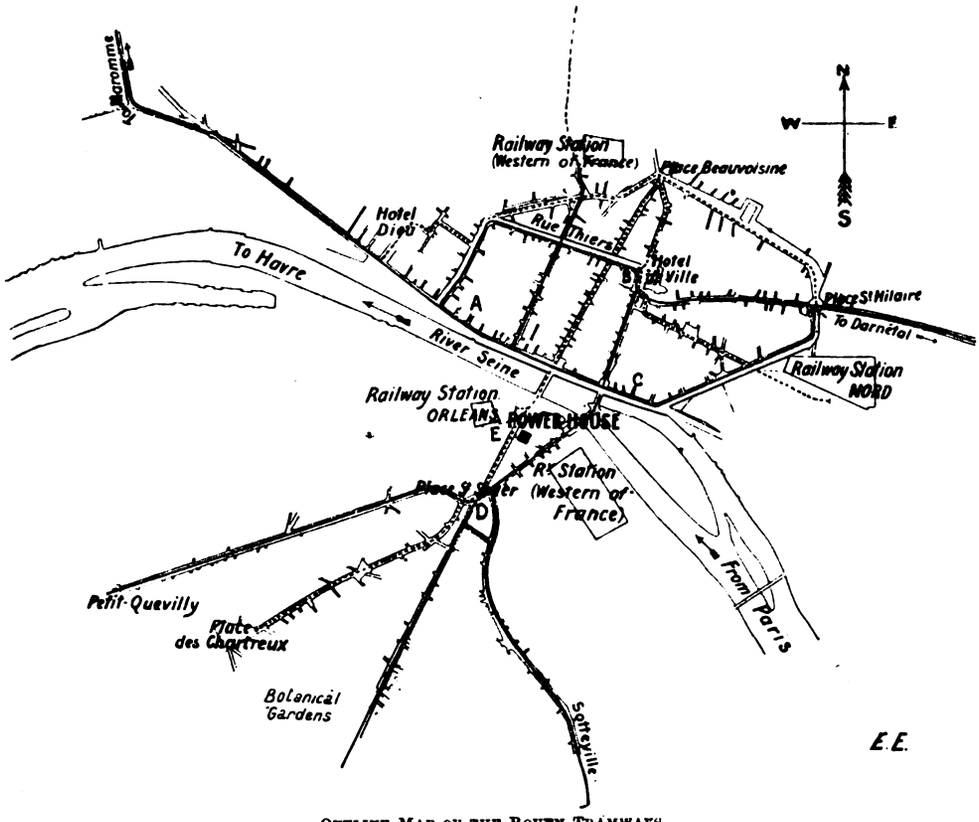
The outgoing feeders, each equal to a section of 200 square millimetres (equal to ·310 square inch), are run from



General View of Rouen, from Bonsecours.

The whole of the new lines, extensions, etc., together with the greater part of the old lines, have been laid with heavy girder rails of the Broca type, weighing 56lb and 88lb. to the yard, according to the traffic, but nearly all of the latter section. The rails are, of course, in various lengths, running

the power-house in five sections, having a total length of rather less than three miles. They terminate at points shown in the diagram by the letters A, B, C, D, E, being run underground in a trench in the roadway. They are lead covered and armoured, and therefore not otherwise protected in



OUTLINE MAP OF THE ROUEN TRAMWAYS.
Dotted lines represent the extensions and new routes opened up. Full lines show the old routes. Feeder points at A, B, C, D, and E.

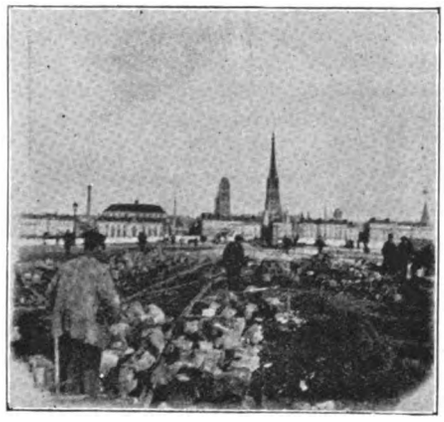
up to 10 metres (33ft.), laid simply on the sandy subsoil without concrete or any attempt at foundation other than is given by continuous tamping whilst being laid. The excellent quality of the soil enables this course to be followed without any apparent subsidence or difference in level

the ground except by the usual wire netting, but iron plates are used to cover them in passing over the bridges, where the feeders are set in shallow brick and cement conduits. In each trench is also laid a return wire of tinned-copper wire (No. 0 gauge), set in a small wooden trough of

Digitized by Google

V section, which is filled up afterwards with melted pitch. From the rails nearest the power-house, heavy return feeders, each composed of a dozen or more similar bare wires, are run to the negative 'bus bars at the switchboard.

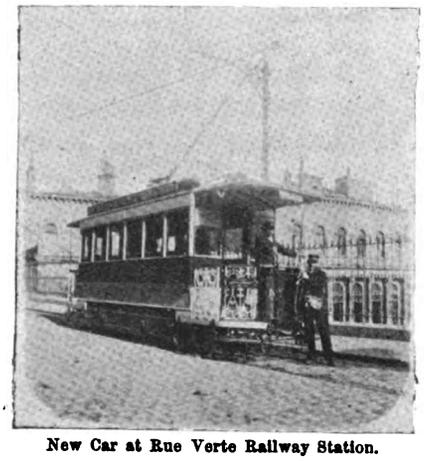
The overhead work largely consists of span wires stretched from steel poles on each side of the street in the usual manner; along the Quais, however, double-bracket poles are used, and in some of the suburbs, as well as along the Boulevards, it is found possible to employ single-bracket poles where the track runs near to the side of the road. In view of the stand that has been made so strongly in this country against the use of span wires, it is interesting to note the approximate distance of line provided with such at



Laying Track across Place St. Sever.

Rouen; there are, roughly speaking, about three times as many span wire poles erected as there are single and double bracket poles, and this proportion holds even along the most crowded and populous streets, such as the Rue Jeanne d'Arc, which is the great shopping and promenade street, Rue de la Republique, Rue Thiers, Rue Lafayette, etc.

Two trolley wires are run throughout the entire length of each line, thus serving not only to lengthen the life of the wires, but also saving heavy outlay upon feeders, as well as complication in the overhead points and crossings. Each wire has a sectional area equal to about 100,000 circular mils. The overhead parts—trolley ears, crossings, points, etc.—are all of the ordinary General Electric type, such as have



New Car at Rue Verte Railway Station.

proved acceptable from long experience in the United States and elsewhere. The poles are all set 6ft. deep in concrete, and in many places (particularly in the main streets) offered no small difficulty to the excavators, who found numerous obstacles in the way of old walls and cellars, not to speak of the naturally hard ground over most of the area covered. At points where heavy strains come on the trolley wires—*e.g.*, at curves, junctions, etc.—large poles 28ft. long and of extra heavy section are employed.

The work at the power-house has been of an extensive and elaborate nature. A suitable site from every point of view was not easily to be found, and that which was eventually decided upon lies some little distance (about 300 yards) from the River Seine, so that river water for condensation purposes is not immediately available. Coal has also to be carted into the yard, though fortunately the railway goods station is near by, as well as the river for barging fuel. At present, the coal employed is from English sources, brought up the river in sea-going boats from South Wales.

The site of the power-house is an irregular rectangle with a frontage to the Rue Lemire on the narrow side. The frontage is to be occupied by offices, porter's lodge, etc. Immediately in front, as one enters the plot of land, is an entrance way leading to the engine and dynamo house—a huge building of iron framework, with brick lining, large top and side lights, and a slated roof. The boiler-house, of solid brickwork construction, with an iron, slate, and glass roof,

New Car on the Quai de la Bourse.

stands to the left in front of the massive brick chimney, 180ft high, set between the boiler-house and engine-house. On the right of the entrance way is the refrigerator or cooling arrangement for dealing with the condenser water, enabling it to be used over and over again. Room is left for the provision of an annexe to the boiler-house, between the offices and coal-store (the latter lying just in front of the present boiler-house). There are at present installed three Babcock and Wilcox boilers, each of 250 h.p. capacity, working at a pressure of 8 atmospheres (120lb): and in the annexe, room is available for two more of the same size. The boilers are fed by a couple of Worthington pumps, the water supply, both for the boiler feed and the condensers, coming from a

Tower Wagon—Erecting Trolly Wire.

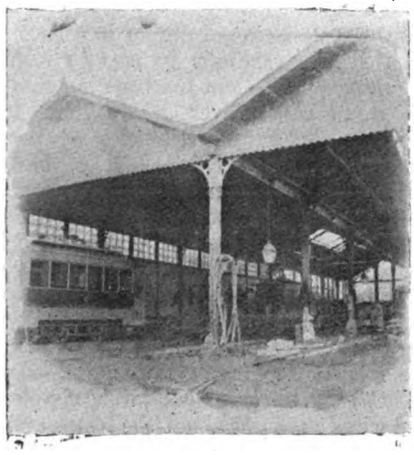
special main put down by the water company, and passing through water-meters in the basement of the offices.

The boiler gases are led through a brick flue into an economiser chamber, provided also with a by-pass into the chimney direct, and thence into the chimney. Hand-stoking is employed at present, as no great saving would be gained by mechanical appliances in a country of low wages, comparatively speaking.

The foundations for the power-house buildings are of a most solid and substantial character. Owing to the fact that the subsoil in this part of the town is largely river gravel resting upon very porous and marshy substrata, it was found necessary to cover nearly the whole area with piles, and at least 150 of these—consisting for the most part of beech

Digitized by Google

piles, 40ft. long and 12in. to 15in. diameter—were driven into the ground under the sites of boiler-house, engine-house, and chimney. On the top of the piles a heavy timber crib-work was built, and filled in with cement concrete. This again was covered with old tramway rails spaced evenly apart, another layer of concrete, then a steel grille, or network of square steel bars, and a final bed of concrete, thus forming a solid foundation 8ft. or 9ft. thick, resting on the top of the piles. There can hardly be any question of disturbance to surrounding property (rather closely inhabited) from vibration, especially with the comparatively slow-running plant employed.



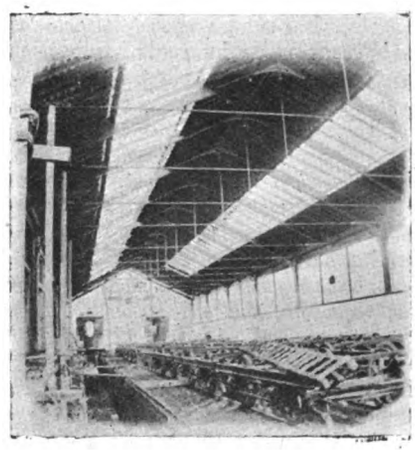
Existing Car-Sheds.

The engine and dynamo house also has an irregular rectangular shape, its length occupying the full width of the power-house plot, one end being corner-shaped. At present it contains three sets of generating plant, each equal to an output of 200 kilowatts; but the dynamos are to be replaced very shortly by 300-kilowatt machines, the engines being fully capable of working up to the larger output. They are of the horizontal condensing type with single cylinders and separate jet condensers, the pumps for latter being operated in the usual way from rocking arms on the main connecting rods. The cranks are of the overhung disc type. Heavy flywheels, about 21ft. diameter (each

New Ca on Place de la Republique.

cast in four pieces), are mounted on the crankshafts outside the main bearing, an outer bearing on separate foundation being provided in each case to help carry the weight of flywheel. The latter is turned on the surface to carry a belt driving direct on to the dynamo pulley; the speed reduction being 1 to 5, as the engines run at 85 revolutions per minute and the dynamos at 425. The engine cylinders being placed next to the dynamos owing to the small space available, it is necessary, in order to have the slack side of belt at the top, to run the engines in reverse fashion, that is, with under, instead of over, stroke for the forward movement of piston. Corliss valve gear is fitted to each engine, and a governor of Proëll type, actuated by eccentric rods and bevel gear from the crankshaft. A neat little arrangement is fitted to each governor for the purpose of checking the speed if excessive variations in load should cause a tendency to run away. When the governor moves beyond a fixed limit, it releases a small valve that destroys the condenser vacuum, and sets up a large back pressure. The engines, like those in the power-house at Havre, have been made by Messrs. Farcot, of St. Ouen.

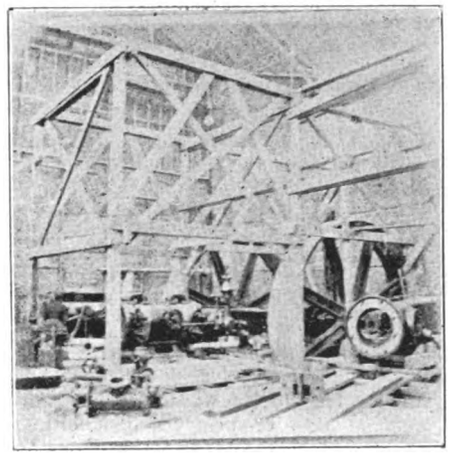
Atmospheric exhaust-pipes, with separate valves, are provided, so that the engines may be worked condensing or not, as desired. The foundation for both engines and dynamos are built up of brickwork set in cement, on the main foundation already alluded to: and in the basement thus formed



New Car-Shed, Filled with Motor Trucks.

under the engine-room floor properly so called is found space for the steam, exhaust, and condenser pipes. The main steam-valves are placed below the flooring, but, of course, each engine has its own stop-valve as well, worked from above. The piping is so arranged that no occasion need arise for cutting out more than one engine at any time for repairs, etc.

The dynamos are of the ordinary compound-wound four-pole type used by the General Electric Company, giving an output of 200 kilowatts; the pressure varies from 500 volts at no load to 550 volts at full load. Special switch pillars and connections are put in to allow of the machines being coupled in parallel. The switchboard itself is also of normal



Erecting the Engines.

type, having three double feeder panels and three generator panels, each provided with switches, resistances, magnetic blow-outs, ammeter and voltmeter connections. There being at present no restrictions in France corresponding with our Board of Trade rules, it is not compulsory to provide testing appliances such as are in use at Bristol; but the engineers of the tramway company will doubtless find that apparatus of the kind is not altogether the product of red-tapeism, but is consistent with, if not indeed conducive to, sound and economical working.

The water-cooling arrangement consists of a large iron erection through which the water is allowed to percolate against a strong current of cold air from a large rotary fan or blower, driven by an electric motor. The cooled water

Digitized by Google

finds its way into a reservoir or tank of brickwork underneath the building, whence it is taken to the condensers.

The rolling-stock now in operation consists of 50 motor cars, 10 more being ordered to fall in with the traffic requirements. Each car is designed for 20 passengers, seated, first and second class, with standing room on the platforms for 20 more. The trucks are each fitted with two 25-h.p. motors, with single-reduction gear of the type now generally used. The controllers, one on each platform, are of the new K.2., or series-parallel type, with nine contacts, so that greater ease of regulating the speed, as well as greater differences of speed, may be obtained.

Each car is fitted with five incandescent lamps, arranged in series, three inside and one on each platform; the result is excellent, and better illumination could hardly be wanted. The cars are painted outside a light-coloured lemon-yellow on the body panels, and white elsewhere, and the appearance is very neat—most of the inhabitants of Rouen expressing decided approval of the cars, just as they have done with regard to the overhead structure, if we are to believe the local Press.

Two of the depôts already in use by the tramway company are being retained for future use, though considerable rebuilding and extending have been necessary. The stables are no longer required, but they are not quite suitable for car barns; at Maromme, therefore, the old stables have been pulled down and a fine new shed of brick, with timber and slate roof, put up, with six tracks, inspection pits being dug under them all. Accommodation is here provided for 20 or 25 cars. The chief depôt, with repair shops, etc., is situated at Trianon, near the Jardin des Plantes, or Botanical Gardens. Here the existing car sheds are being used, inspection pits being dug, however, under them at the entrance of the tracks; a new car shed alongside, with four tracks, accommodating also 20 to 25 cars, has been built. The repair shops are close alongside the latter. At both these depôts the use of a traverse table has been abolished, separate tracks being radiated into the car sheds from the main entrance track, so that in case of fire the cars may be run out of the sheds in a shorter time than would be possible with the use of a traverser.

The work of construction and equipment was begun in April last, and the entire change has therefore required close upon 10 months to effect—not at all too long a time considering the amount to be done. Indeed, the overhead work and the power-house construction has been done practically within the last seven months only. The cost has been heavy, as might be believed, the total outlay being at least £200,000.

The contracts entered into have been between the Tramways Electrical Traction Company, Limited, and the Rouen Electric Tramway Company in regard to the financial aspects of the work, also between the latter interest and the contractors for the work. These were the French Thomson-Houston Company, who took in hand the supply of all power-house plant, including the erection of chimney, etc., car trucks, motors and gear, and the overhead construction throughout, also the laying of feeders and fixing of bonds, etc.; the Brush Electrical Engineering Company, Limited, who supplied the car bodies; Monsieur U. Légé, contractor for the new buildings, power-house, etc.; and Monsieur E. Massicard, who carried out the whole of the permanent-way work at an average rate of nearly half a mile per week. Since the lines were opened, the Thomson-Houston Company (Compagnie Française) and its allied interests have shown so much confidence in the future of the system that the English interests have been bought out, and the Rouen tramways are now owned entirely by the French themselves.

In carrying out the work and in preparing for it, much credit is due to all concerned. For instance, the negotiations with local authorities, resulting in a prolongation of the tramway concession for practically 50 years, also the dealings with city and State officials, have been almost entirely in the hands of Monsieur M. Mancini, the local director of the Rouen Tramways Company. The supervision of all permanent-way work and rolling-stock was assigned to Mr. C. W. Gordon, who was sent over two years ago as manager of the company, and upon whose report, together with that of Mr. J. Clifton Robinson, C.E., the well-known tramway expert, it was practically decided by the tramway company to adopt electric traction. Mr. Gordon, since the completion of the work at Rouen, has accepted the managership of an important tramway system in Bucharest (Roumania). The engineer in charge of the work on behalf of the Compagnie Française Thomson-Houston was Mr. G. S. Albanese; and Mr. Frank B. Lea (whose name will be doubtless well known to our readers) has acted throughout as resident engineer for the Tramways Electrical Traction Company.

CENTRAL-STATION WORKING—LINE AND STATION EXPEDIENTS AND METHODS.*

BY E. B. NEWCOMB.

Soon after the installation of lights in a large paper mill it was found that the renewals in certain localities were excessive, the lamps giving out in the filaments after only a few hours' run. Upon investigation these lamps were found to be located near statically-charged paper in process of manufacture, or within the influence of highly-charged belting. In order to determine with certainty whether this was the cause of breakage, disconnected lamps were held in the hand and presented to the moving belts. After some careless handling, in which the Leyden-jar effect of a lamp was most emphatically demonstrated, it was found that a violent agitation of the filament took place, and in some cases powerful enough to fracture it. How then to make the lamps proof against this influence was the problem. The remedy employed was simple: two or three pointed wires were put about the lamps and connected to the socket, somewhat after the manner of attaching a shade-holder. By connecting the socket shell, if not otherwise grounded, to one wire of the circuit, a passage was made for the discharge and no further trouble was experienced.

A more weighty problem, however, soon presented itself. The mill in question was at first lighted by direct current, but was afterwards connected to an alternating circuit, the transformers being grouped in one locality. There were 1,300 lights. As the generating plant was made up of 1,000 light factors two alternators were required for this work. One was given a full load and the other took the balance, together with a partial load of commercial lights. The main circuits and feeders, both primary and secondary, ran parallel on the same cross-arms and structures for a larger part of their length. Everything worked satisfactorily, with one exception; lamps in certain localities at the extreme end of the distributing mains gave an unsteady light. The appearance of these was like that produced by a slack driving belt slipping at regular intervals of revolution; such, for example, as occasionally takes place in a manufactory near our station, lighted by its own plant, where the effect of a slipping belt is clearly shown by the regular up-and-down movement of the lights throughout the building.

We could not attribute our trouble to this cause, however, as it was confined to only a part of the lights. It did not occur when one alternator only was running, with part of the circuits idle, or even with the latter supplied by direct current from the old dynamos. The frequency of the fluctuations was found to depend upon the relative speed of the two alternators. It was then decided that induction must be the cause of the variation. The waves of current, if not in phase, alternately matched and mismatched, much on the principle of two piano strings, nearly, but not quite, in unison, making a noticeable wave in the tone produced. A corresponding variation was also noticed in the humming of the alternators at the station. It was clearly evident that induction did not take place in the primaries, because no commercial lights were affected. It must then be at the mill in the secondary mains having the heavier current. Believing this to be the cause, we lost no time in crossing all of the secondary feed-wires of one of the systems at about the middle of their length, as in Fig. 1, and were gratified to find a greater part of the trouble at once removed.

Later, we had a similar experience in another quarter, where the induction took place in the primaries. Circuits from two alternators ran for about a mile upon the same

* From the *Electrical World* (New York).

Digitized by Google

four-pin cross-arms. The two inner wires carried 50 amperes of current, while the two outer wires were lightly loaded with the current required for a small number of house lights. Customers upon the latter line complained that their lights had the disagreeable appearance of trembling, as if the filaments were shaken by a jar. Not having any suitable circuit breakers at hand, we put an extra cross-arm half a mile down the line, and, cutting the outside wires,

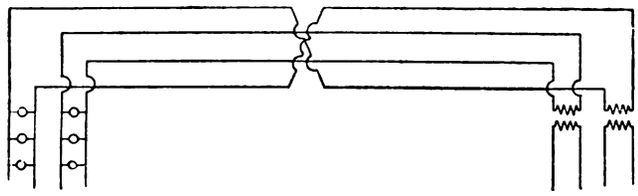


FIG. 1.

crossed them over. Our customers experienced no further trouble; in fact, they could not detect any traces of the former variation even upon closest inspection.

Our station was first equipped with direct-current apparatus distributing by the three-wire system. Later, we extended our territory and supplied lights by alternating current at points six miles from the station. So successful has been our experience in lighting with alternators that, were we to begin over again, we would discard direct-current apparatus altogether. The current from an alternator is so easily transformed to required voltages for various purposes that it leaves almost nothing to be desired.

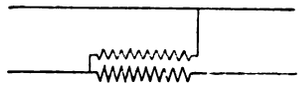

FIG. 2.

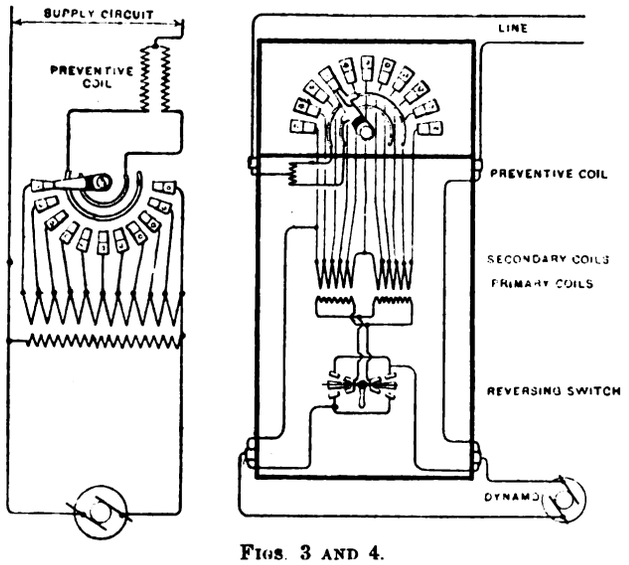
By means of additional transformers arranged with the secondary coils in series with the line, as in Fig. 2, the initial voltage can be further raised or lowered according to the relative direction of the current through the primary coils.

This general principle is exemplified in the Stillwell regulator, where provision is made for changing the length of the secondary coil, as well as reversing the primary current. With this device shown in Figs. 3 and 4, the voltage can be changed up or down 20 per cent., or a total of 40 per cent., in steps hardly noticeable. By means of



FIGS. 3 AND 4.

one of these regulators we are able to supply from the same alternator 1,100 volts for distribution at a centre one mile away, and by step-up transformers 2,200 volts for service five miles away. With the switchboard adjustment for one of the circuits and a regulator for the other, both branches are easily kept at the proper potential for the varying loads on each.

This step-up principle was put to practical use in transforming for the mill lights previously mentioned. Our standard lamps were 108 volts, while theirs were 120 volts. As a part of their lights were connected to our regular circuits, we found it desirable to retain our standard voltage and transform to that required. Two auxiliary transformers were used, one 1,000 to 100, and one 1,000 to 50, as in Fig. 5. With an initial potential of 1,100 volts, one transformer increased it 110 volts and the other 55 volts, making a total of 1,265 volts, which, transformed 10 to 1, gave as a resultant 126½ volts at the switchboard of the mill plant.

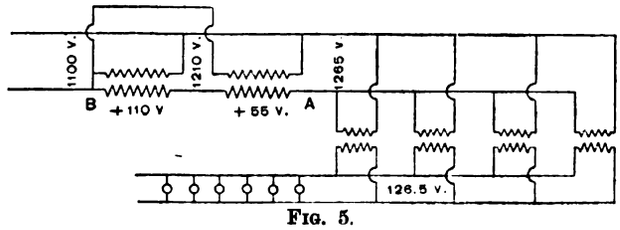


FIG. 5.

By connecting the primaries of the auxiliary transformers at A instead of B, a still higher voltage could be obtained. This would be 1,294·1 volts, made up as follows: 1,100 V. + 129·4 V. + 64·7 V. = 1,294·1 V. A still further change could be made by the use of smaller transformers for varying the primary currents of the auxiliaries, or by connecting the primaries in series. Fig. 6 shows how it would be possible to change our 2,200-volt circuit to one of 3,300 volts, and yet use only

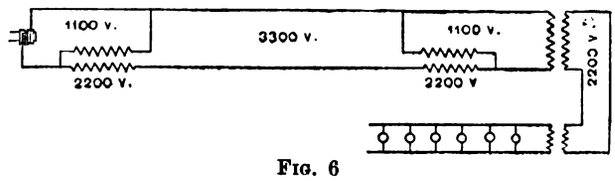

FIG. 6

our present 1,000 to 2,000-volt transformers. What would be the result of a reversal of the primary wires in this case would be a question perhaps for discussion.

It will thus be seen that a great variety of results can be attained with ordinary transformers without recourse to specially-wound apparatus for the purpose. In the cases cited, no transformers larger than 250 lights capacity were used, four of the latter having been connected in multiple, on both primary and secondary wires, to supply the maximum current mentioned. It is the practice on our lines to connect two transformers in multiple whenever one is not large enough for the service. This method allows the adoption of a standard size of transformers, say, 30 lights, for general use, so that a spare transformer or two on hand will serve for replacing any that may give out throughout the system.

In direct-current distribution the system of connecting generators in multiple has long been in use. Series work has not been so common, excepting, perhaps, as it has been found in the well-known three-wire system. That motors can be run either in multiple or in series is perhaps not so widely known. A combination of the two methods in generators as well as in motors, as shown in simple outline in Fig. 7, is rarely found. This represents an existing power plant which has been rearranged to transmit in either direction. The machines are shunt-wound, the compound

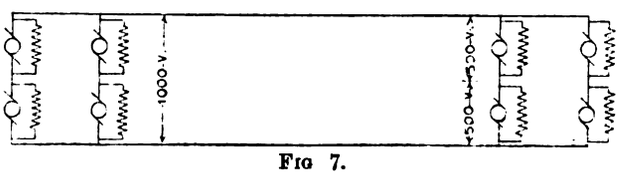

FIG 7.

winding of the original generators having been disconnected to prevent reversal when running as motors. The E.M.F. of each is 500 volts, making that of the line 1,000 volts. The motors and generators are belted respectively to one line of shafting, the pulleys having been proportioned to the relative speed of the armatures running independently as motors, without load. The machines are made to work together by means of field rheostats. No starting rheostats are needed, as either plant can be run at a speed corresponding in potential to that of the other before the

Digitized by Google

connecting switches are closed. The load is taken up by lowering the voltage of the machines desired to work as motors, and raising it at the generator end. The transition from motors to generators is thus easily made, and so smoothly is it done that on light loads a comparison of the terminal voltages by telephone is sometimes necessary in order to determine the direction of the power.

HIGH-VOLTAGE LAMPS, AND THEIR INFLUENCE ON CENTRAL-STATION PRACTICE.*

BY G. L. ADDENBROOKE, MEMBER.

(Concluded from page 293.)

The Use of Accumulators.

This brings me to the fifth and last point mentioned at the beginning of my paper when enumerating the possibilities likely to affect central-station practice in the future—viz., the use of accumulators. In the earlier part of 1891 I did not see much likelihood of improvements in accumulators making any really fundamental alteration in central-station practice. But I must confess that in this respect events have moved faster than I anticipated, although I have been brought sufficiently into contact with them to learn what was going on in the field, and how batteries were doing as regards upkeep. Up till comparatively recently, there is no doubt accumulators have been rather a luxury and convenience in central stations than a commercial or economical necessity; but during the last two or three years considerable changes have been taking place. The maximum safe discharge rate for accumulators has been going up, while the initial cost has been going down, as well as the cost of upkeep; and extended experience holds out the hope of much longer life for the newer and improved forms of positive plates than has hitherto been the rule. Owing also to the method of supplying accumulators at a maintenance rate adopted by the leading firms, an engineer need have less hesitation in recommending clients to incur a large expenditure on them, and the risk is much less than formerly. Patents are also expiring, and considerable competition is arising in this trade, which was formerly such a close one. I have lately had to make careful enquiries about accumulators in connection with work on which I am engaged, not only as regards prices, but also as to their working, and, having got particulars about the batteries in several central stations, and held conversations with the engineers concerning them, have been considerably surprised at the progress which has been made. Taking quotations from leading makers for a battery suitable for a central station, I find that the capital cost of a battery to discharge at one kilowatt for three hours is as nearly as possible £13 for the battery alone. Several makers assure me that such a battery can be discharged at this, and even higher rates, every day regularly, without detriment or endangering the life of the positive plates. The above price does not include buildings to contain the accumulators, connections, instruments, or stands to hold them, which bring up the cost to about £19 per kilowatt on this basis for central-station batteries. The makers tell me further that they are willing to enter into contracts to maintain such batteries in a state equal to new for about 6 per cent. per annum on their capital cost, and some makers will even go lower than this. It will be found that these costs and rates of renewal are a great improvement on those ruling until comparatively recently. Now, I should not quote these figures unless I had, by private enquiries and in other ways, fairly convinced myself of their substantial accuracy. Granting that they are so, it appears to me that they raise questions of very serious import in central-station practice, particularly when coupled with the use of higher-voltage lamps. If an accumulator will give a discharge for three hours—that is, sufficient to cover the period of heavy load, or the time during which the large portion of the plant has to be kept running—a kilowatt capacity of accumulators will be equivalent to a kilowatt capacity in engines and dynamos. In continuous-current stations, when an increase of output is required—which is from time to time the position of most stations—we are therefore brought face to face with this problem. Extra plant for 200 kilowatts output, say, is required. Which is the best way of providing for it—by adding engines and boilers, or by adding accumulators and charging them during off hours from the existing plant? Now, as I have said above, an accumulator for an extra kilowatt output will cost about £19 complete and erected, including buildings; and I think engineers will generally agree with me that engines, boilers, dynamos, and steam-pipes for a kilowatt output, including buildings, and all other accessories, would cost about the same sum. If foundations, flues, chimney stalk, and everything else were considered, the comparison would be slightly in favour of accumulators. However, for our present purpose, let us assume that they are equal. We have therefore arrived at the position that the capital cost will be equal, whether we provide extra plant or extra accumulators for the increased output required, charging the accumulators from the existing plant.

As regards upkeep, if we can keep the accumulators in an efficient state for 6 per cent. on their cost, this is not greatly in excess of what would have to be allowed on plant if boilers are included, and, at any rate, the difference is not a matter of very great moment. There is no need to say anything here on the extremely low cost at which energy can be produced if a continuous load is provided night and day. Considering the advantages accumulators give in a central station providing for emergencies, reducing staff, and keeping the pressure even, it is, I think, doubtful if an engineer placed in the position indicated above—as many engineers will be placed shortly—would not be wise in recommending his corporation or his board to instal accumulators for 200 kilowatts output for three hours, instead of the extra plant, when the plant was a continous one. How far this should proceed is a moot point, dependent upon circumstances, which would need decision in each case. Possibly somewhere about one-third the maximum full-load capacity would be about right now, but with a load-factor of 10 to 15—which is about that general in central stations—if the price of accumulators came down per kilowatt output—which I think it is likely to do in the future—or their efficiency increased, it might be found desirable to instal accumulators for as much as two-thirds, or even three-fourths, of the full load, which would place electric distribution nearly on a par with gas distribution in respect to storage. To go as far as that is, however, not a question of the present—at any rate, in most cases—and therefore for our purpose this evening I propose to consider the accumulators as desirable for about one-third to one-half the full output.

It may be useful here to give a few general data relating to accumulators as they stand at present. The leading makers' prices of central-station batteries work out at about £13 per kilowatt on a discharge for three hours for the plates, cells, and acid only, whilst, including stands, erection, connections, and switching arrangements, the price works out about £17 per kilowatt, or, if buildings also are included, about £19 per kilowatt. In such a battery I find the plates and lead cells alone would weigh about 8cwt. per kilowatt output on the three-hours' discharge basis, and that 1cwt. of plates and cells costs a little under £2, or the cost comes to about £40 per ton. Now, as lead costs under £12 per ton at present, and seeing how much almost pure lead in a very simple form there is in accumulators, it does not seem unreasonable to anticipate that in the future, when accumulators are made on a much larger scale, we may see the price gradually come down to, say, £25 per ton, with, perhaps, improved capacity and life. At least, it appears to me that there is as good hope in this direction as there is of reduction in price and improvement in quality in any other department of electric engineering. If such a consummation were attained, it is pretty clear that it might pay to use accumulators for power stations, as well as lighting, wherever an eight or nine hours day was in vogue, and that they may ultimately come to exercise a much wider influence on the future of the electric industry than most engineers have anticipated. In order to gauge in some measure what has been the improvement in accumulators during the last few years, and since the question of the system of central-station supply was last prominently before this Institution, I lately took an opportunity of talking the matter over with Mr. Epstein, and I asked him if by looking up old contracts and catalogues he could give me anything definite on the subject; in reply, he has sent me the following letter: "I have looked into the question of the prices of accumulators, and I find that, comparing the prices in 1890 with the present ones, there is on an average a reduction of 25 per cent. But another and more important point is this—that whereas the types then manufactured were only allowed to be discharged in about 10 hours, necessitating in the case of shorter discharges much larger batteries than required for the purpose, the discharge rate has since then increased very considerably. Taking one with the other, I think I am justified in saying that the reduction altogether amounts to quite 50 per cent." In view of these facts, and considering that it is now the custom to buy accumulators on a moderate maintenance agreement, and also all the added experience of the last five years' work, it will be at once evident on how much sounder a basis commercially accumulators now rest, and how much stronger the arguments in favour of their employment in central stations are than they formerly were. Upon the three hours' discharge basis, I find a kilowatt capacity of accumulators occupies approximately four cubic feet space, for the cells and connections, so that we get a kilowatt-hour into 1·33 cubic feet. Now a discharge of a kilowatt-hour, allowing for losses, will keep about 15 16-c.p. lamps going for one hour. Allowing that a gas-burner using 6ft. of gas per hour is equal to a 16-c.p. lamp, the amount of space needed in a gasometer to store gas for the same amount of light

* Paper read before the Institution of Electrical Engineers, February 27.

Digitized by Google

is $6 \times 15 = 90$ cubic feet, or 70 times as much space. Of course this is not quite a fair comparison, because nothing is allowed for stands, access, etc.; but I think it will be quite fair if we allow 10 times as much space for access, etc., as the accumulators take themselves. Even under these, the actual conditions, accumulators only occupy one-seventh the space which the equivalent gasometer would. We arrive, therefore, at the curious conclusion that, if the London gasometers were emptied of their gas and fitted up as accumulator-rooms, sufficient accumulators for lighting London could easily be arranged under working conditions in one-seventh of the space which would be available. We have, therefore, nothing very enormous to fear in the way of accumulator-houses, even if accumulators are used in the future on the most extensive scale for lighting or power purposes.

Interesting as these speculations are it is desirable, however, to return to what is more specifically our subject. It is usual at present to place the accumulators in the central station, except in a few instances, such as in Mr. King's system at Chelsea, Mr. Parker's Oxford system, and a few special places. Usually under these circumstances the accumulator is subject to the heavy drop at full load, which decreases its efficiency by 10 to 15 per cent. With 220-volt lamps the drop on the feeders within a mile radius would be much less than is usual now, and therefore the value of the accumulators would be correspondingly increased. For longer distances from the central station than a mile, however, undoubtedly the right place in most cases for accumulators will be at the feeder points. This is the more feasible with 220-volt lamps than under present practice, because the distributing network is so much larger from each feeder, and each feeder becomes the centre of a serious amount of lighting which will pay for individual attention. Although from the table I have given the cost of copper per lamp installed for feeders is very moderate, yet on a two-mile feeder it amounts to a considerable sum in the aggregate, and if by installing accumulators at the end of the feeder for one-third to half the full output the section of the feeder can be cut down by one-third or a half a very important saving is effected, and, of course, if accumulators for two-thirds or three-fourths full load were installed the cost of feeders would be correspondingly reduced. This has already been recognised in practice, and many devices have been brought out for charging accumulators in series or by the help of motor transformers using a high-tension current; but I would point out that the use of 220-volt lamps on a three-wire system does away with the necessity for any of these complications. All that is needed is a continuous-current motor transformer of the "booster" type. In this, one armature circuit is across the mains, and wound with a high resistance and many turns, while the current to the accumulators passes through the second circuit direct, the second circuit being wound with a few turns, so that the voltage of the main current in passing through the armature is raised, say, 30 per cent. The motor transformer then need only be about one-third the capacity for the charging current, and the cells can be charged at any time while the circuit is supplying lamps, so that continuity of supply without complication is ensured. By these means the cost of long feeders would be much reduced on the figures given above, which means also that it would be practicable to extend the lighting radius much further than was contemplated above at the same cost, should it be needed. An important factor is also brought in—that, having once laid a feeder of fair size, accumulators can be added at the outer end as the lighting grows, and thus a very large increase of lighting could be gradually met without relaying the feeder or disturbing the streets, which is always an expensive and troublesome operation. In what I have said above I have indicated a feeder to each half square mile as an average, or four to the square mile; but it is clear that if accumulators were employed, and it were desirable to concentrate them in order to save labour and attendance, it would be very simple to run short sub-feeders from a centre, so that one distributing point where accumulators were situated and one feeder from the central station could be economically made to serve a square mile or more. It is further worth noting that at 220 volts the cutting in or out of a cell makes less than 1 per cent. difference in the voltage, and not 2 per cent., as at present. This is an important consideration in keeping the light steady—a point the importance of which is becoming more and more recognised. The convenience of the system for arc lighting does not need pointing out, as nine arc lamps can be run in series. One more point is the effect which a general electric supply at 220 volts on the lines indicated above would have on the power-supply question. There is no difficulty in procuring already motors of any size from 50 watts upwards to run on 220-volt circuits, the number of amperes they take being, of course, half what is usual now; while for larger sizes, say above three or four kilowatts, they could, of course, be coupled across the two outers at 440 volts. If we then add the facts that the drop on the feeders would be less than at present, that the current density in the distributing system on the basis I have laid down would only be about half what it is at present—and when we consider that there would only be 1½ per cent. fall of pressure at full load on the distributing mains, and that by cross-coupling even this would be reduced—then it seems to me that it goes almost without saying that motors could be used to a far greater extent than at present is possible without appreciably affecting the regularity of the lighting. Accumulators at the feeding points would also be an important aid in this respect; if they were so used, the fall of voltage from them to the motors would rarely exceed 2 per cent., and under such circumstances motors of considerable size could be started and stopped (even without special starting resistances) without the rush of current being perceptible on neighbouring lamps. In this respect, therefore, the use of 220 volts is likely to be very advantageous, and do away with the necessity of having to lay special power mains—for some years, at any rate. The utility of having generators in the lighting stations giving the current and voltage which is needed for tramway work is also obvious; in fact, it looks as if one station in future would do all the power supply for a town, the lighting being only one adjunct of its business, and that, possibly, not the largest. With most of the lighting done by means of accumulators charged during the night, and the station supplying power to the tramways, etc., during the day, it ought to be possible to secure a very fairly even all-day load with one set of plant, instead of two, as at present. This would, of course, lead to important economies in generating expenses. In fact, it looks as if we could already see far enough ahead practically to enable Mr. Preece's prophecy to be fulfilled in a moderate time—"that the electric light would ultimately be the light of the poor man as well as of the rich."

And now I must conclude. The title of my paper was "High-Voltage Lamps, and their Influence on Central-Station Practice." In the first place, I have endeavoured to show that high-voltage lamps are thoroughly practical. Next, that high-voltage lamps are more desirable than lamps of the usual voltage and of high economy. I have also shown reasons why it is probable that the economy of high-voltage lamps may in time nearly approach that obtainable in ordinary voltage lamps. Having thus tried to establish the soundness of the position of the high-voltage lamp itself, I went on to consider what influence the adoption of a high-voltage lamp would have on central-station practice. I have shown how it simplifies and renders less costly the distribution of current, and how it improves the conditions of lighting. I think I have further made it fairly clear that for nearly all practical requirements of town lighting the direct-supply system will prove simpler and less costly, as well as more advantageous, than any system, whether direct or alternating, in which transformers are used; in fact, the necessity for this class of apparatus, except for special cases, seems to vanish. I think, therefore, that when the facts are fairly faced there does not seem much doubt that those engineers who have advised their clients to erect continuous-current direct-supply stations in the past have done wisely, and will be found to have served their clients' best interests; and that for the future alternating-current stations, even for country towns and scattered districts, should only be erected after the most careful weighing of possibilities. It is considerations of this character which have led me to keep very much in the background as regards central-station lighting for the last four years. Having been associated from the early days with alternating currents, my predilections were in that direction; and although the position seemed secure, yet, seeing the possibility of great improvements in several directions which would tell strongly in the favour of direct supply (but the exact advent of which no one could actually foretell until it arrived), it seemed to me more prudent to turn one's attention to other things for the time than to incur the risk of recommending work which might soon have to be undone. I have always expected and looked forward to a time when there would be one system of lighting, with variations merely in details, and have felt that the rivalry between the two systems would some day end as the battle of the gauges ended in the early railway days; and I think there are signs of the end now. It seems as if the narrow gauge would win again—as if the tortoise would again beat the hare, though it is true that to do so the tortoise has had to improve its pace considerably.

Newcastle-under-Lyme.—Major Marindin has held an enquiry for the Board of Trade respecting the objections made by the Corporation to the proposed provisional order of the promoters of the electric tramway scheme for connecting Hanley with Newcastle. Mr. Milward, of Birmingham, appeared for the tramway promoters; and Mr. S. Watson (from the office of the town clerk) represented the Corporation. Mr. Milward said the total length of the proposed tramway was something under three miles, of which 1,376 yards were in the area of the borough. He understood that one objection of the Corporation was in consequence of communication with Silverdale and Chesterton not being included in the present scheme, but he offered, if the opposition were withdrawn, that the promoters would pledge themselves to apply for powers to extend the line to Silverdale and Chesterton. Circulars had been sent to 4,055 ratepayers of the borough, 2,809 of whom had signed in favour of the tramway project, and only 453 against.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

RATES, ROADS, AND ELECTRICITY.

We have come to the conclusion that if horses, mules, and asses are to be abolished from street and road traction, the very best motor that can be had in exchange will and must be of electrical origin. At the present time, however, steam, gas, and oil are more practicable and more favoured. Efforts are being made to modify the law in connection with automatic motors, and it behoves everyone interested in the subject to strengthen the hands of those moving in this direction. Will it be advantageous to replace animal by inanimate traction, and to whom? Take the animals first. Mr. T. H. Brigg, in a recent paper before the Society of Engineers upon the mechanics of horse haulage, emphasised certain points of bad design leading to increased percussive action upon the feet and legs of the draught animals. Roughly, the percussive action is equal twice the weight of the animal and the weight added by bad design or necessarily added. We have little to say from the sentimental point of view—the damage to horseflesh by the present system. The point rather we wish to make is that which appeals to the pockets of ratepayers. Few electrical engineers know aught of street construction or maintenance. They could not—it is not their business—point out the differences in construction cost, in maintenance cost, in life under given conditions of the various street-paving materials now in vogue. Wood—hard or soft—macadam, granite setts, etc., are to them, and justly so, a sealed book, but to municipal engineers and ratepayers are subjects of the greatest interest. The latter have to pay the piper, and the former have to design, construct, and maintain. Now there is a consensus of professional opinion that more damage is done to the streets by the percussive action and the gripping and slipping action of the horses than by the wheels of vehicles. Assuming this opinion to be correct, the question immediately arises, Will the wear and tear of auto-motors, or whatever they are to be called, be less or greater than the wear and tear of horse traction? If the reply be that it will be less—we believe it will be much less—then a saving at once accrues to every ratepayer, and this is a consummation pre-eminently desired. The local burdens in the shape of debts—not to speak of burdens not so distributed over a series of years—have increased enormously of late years. Many of the local debts have been incurred for street construction or improvement. Money borrowed for street construction is repaid over a number of years, and it may be assumed, for example, that money borrowed for the purpose of paving a street with hard wood must be repaid by the end of the life of that hard wood. Any means whereby such life can be extended, then, will lessen the annual repayments, and so in this particular lessen the annual demand on the rates and on the ratepayers. Once bring these ideas home to the mind of the general public, there will be less hesitation in countenancing innovations. We appeal not only to owners of horses and carriages and carts, but to those who are not so blessed or cursed. There is to be a money saving all round; and an Englishman is understood to be

Digitized by Google

most vulnerable in his pocket. It is a libellous insinuation, of course, but it fulfils a purpose. The electrical engineer ought to be looking ahead. The more rapid construction of tramways is all very well, but the amount of electrical energy required for tramway work, even if all tramways were electrically equipped, would be a mere fleabite compared with that required for vehicular traffic if all vehicles were electrically equipped. The most promising method seems to be self-contained cars, but the makers of accumulators have lost heart or come to the conclusion that we ask the impossible. We could point to other industrial operations wherein hundreds of thousands of pounds were lost, and governments in vain offered prizes, and those who ought to have known better turned back under the verdict impossible; yet the final result is absolute and unqualified success. In one particular case of the kind the successful operations are of the simplest, and, to those who knew the efforts made to reach success, of the most laughable kind. Success was achieved by an intelligent and scientific examination of the whole problem. The chemical actions were carefully analysed, and, as we say, the experiments led to success. It is not too much to say that up to the present we have had no similiar investigation into accumulator work in connection with traction work. That success is impossible we deny. But allowing it is in the dim and distant future, have electrical engineers nothing to say as to other possible methods? Are they going to let steam, gas, and oil have it all their own way? Still, if we are to wait for accumulators, is it not possible that a modified success will lead to better construction of streets and less jolting, which is said to kill the accumulators? We trust that more attention will be given to the whole subject.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE NEW PHOTOGRAPHY.

SIR,—Great improvements have been made during the past few weeks in the Röntgen photography, and the process has now been sufficiently developed to render it of practical value in surgery and medicine. Its successful application, however, requires expensive apparatus and special appliances, the working of which necessitates some technical knowledge.

Under these circumstances, acting on the advice of several eminent physicians and surgeons, I have decided to establish at this address a laboratory specially devoted to the purpose. This will be equipped with the most improved apparatus, which will be added to as experience and experiment show to be advisable. The work will be carried out under my supervision by one of my assistants, Mr. H. L. Tyson Wolff.

It is hoped that these arrangements will prove of service to medical men who may desire to have the process applied to their patients. The laboratory will, it is expected, be in working order in the course of a few days.—Yours, etc.,

A. A. C. SWINTON.

66, Victoria-street, S.W., March 11, 1896.

Bolton.—The electrical engineer has been instructed by the Corporation to furnish an estimate of the cost of laying electric mains in Bowker's-row.

REVIEWS.

Submarine Telegraphy, and other Papers. By JAMES BELL, A.I.E E., and S. WILSON. London: *Electricity*, 29, Ludgate-hill.

This pamphlet contains some papers which originally appeared in the columns of our contemporary *Electricity*, with certain additions. If the contents of this little work are taken as incentives to further study, they will be valuable; if the reader assumes that when he has mastered their contents he has nothing further to learn, he will be wrong. The information given requires some preliminary knowledge as well as a continuation of study. It is, as far as it goes, fairly accurate. We think, however, that Appendix A hardly corresponds with the rest of the volume. It is a doubtful advantage to interpolate the high pressures and currents of electric lighting with the perhaps equally high pressures but infinitesimally smaller currents of submarine telegraphy. Still, we quite agree that electric light people have steadily ignored the knowledge of telegraphists. One value of this little book must not be ignored, in that it will assist the memory of those who are engaged in submarine cable work.

A First Book of Electricity and Magnetism. By W. PERREN MAYCOCK, M.I.E.E. Second edition, revised, corrected, and enlarged. Whittaker and Co.

We have been somewhat remiss in noticing this book, which was issued last year, but, if it is any excuse, quite a number of more pretentious books are in the same predicament. A large part of this book is filled with elementary facts, clearly explained and amply illustrated. In the case of Fig. 12, which shows the magnetic field of a horseshoe magnet, we are of the opinion that the illustration is slightly incorrect. There may be, and no doubt will be, differences of opinion regarding some theoretical points, but

Digitized by Google

no one is in a position to say this theory is the only correct one. The great object of an elementary book is to try and give the known facts and phenomena and explanations of those facts and phenomena in such a manner that the young student will not have to unlearn anything. That this book is a second edition goes to prove that its contents have proved acceptable to readers.

Electrical Engineering Leaflets. By Prof. E. J. HOUSTON, Ph.D., and Prof. A E KENNELLY, F.R A S. Three Vols.: Elementary Grade, Intermediate Grade, Advanced Grade. The *Electrical Engineer* (New York).

These three volumes contain a mass of practical information, put together in an excellent manner, such as can hardly be found in any other work. Perhaps the great disadvantage these volumes possess is that they must be looked upon as a whole, and from the manner of their publication may not commend themselves to the ordinary reader. Each volume traverses somewhat the same lines, but each is a step in advance of the preceding one, each consisting of 35 leaflets, originally issued weekly, and here combined to form these volumes. However, we are more concerned about the matter than the method of presenting it, and here we find little cause for adverse criticism. Every effort seems to have been taken to give clear and simple information; historic disquisition is altogether absent. The authors have evidently in each leaflet taken a text and gone straight to the mark. The dynamo is explained as it is, not as it has been evolved; similarly with the battery, motor, transformer, and other pieces of electrical apparatus. Existing theory and existing practice is the mainspring of the work, commencing with electrical effects, E.M.F., resistance, current, Ohm's law, and even through the dynamo to incandescent lighting, arc lighting, alternating currents, alternators, and alternating-current transformers. The more important subjects occupy two or three leaflets, but usually one leaflet is devoted to each branch of the subject. If there is one objection we should raise, it is not that the authors are not up-to-date, but that they are a little too previous. They hasten to adopt magnetic units which are not universally adopted, and which we think are not altogether suitable. Our readers will remember that the suggestions at the last meeting of the British Association did not meet with fervent favour, though a contemporary played the boom for all it was worth. The authors adopt the suggestions from America for the names of the magnetic units:

$$\text{The webers} = \frac{\text{gilberts}}{\text{oersteds}}.$$

We think our names just as good—

$$\text{Lineants} = \frac{\text{pressants}}{\text{resistants}}.$$

And we neither offend the dead and gone nor the living. But as to suitability, take the gilbert, which the British Association calls the gauss. It is about four-fifths of an ampere-turn. Now, it is absolutely certain that practical men will continue the use of ampere-turns, and will not be bothered, if they can help it, to a multiplication by $\frac{4}{5}$ or $1\frac{1}{4}$ as the case may be. As for writers of books, they will probably welcome any proposed change that will make previous books out of date, and the last issued the only one up to date. So also professors who will talk learnedly about the sun growing cold in 10^x million of years, as if anyone cared a cuss about the matter except themselves and those whom they desired to impress as to their fitness for election into the Royal or other society. We have been led away over this point when 90 per cent. of the books has our highest commendation. The diagrams, the explanations, and the numerous concrete examples are excellent.

Electrical Engineering as a Profession: How to Enter It. By A. D. SOUTHAM. Third and Revised Edition. Southam and Co., 29, Paternoster-row, E.C.

The author in his preface to the third edition of this book says: "It has been thought advisable to draw out a general scheme of study for those intending to compete for one or other of the numerous scholarships and free studentships offered by the public technical institutions, and this programme is also suitable for those commencing practical work with a firm who desire to study in the evening." We would suggest that "the studious firm" in question should consult the prospectus of the Central Technical College, as the author's scheme so advisedly drawn is a badly cut extract from the same, and also is extracted without acknowledgment. It leads one to suppose that in arithmetic "demical extraction of square and cube roots," whatever that may be, and "the use of logarithms" are the only two points requiring the attention of the rising engineer. Generally, we suppose this book will give some idea to a parent of what training to give his son, but the question of the real worth of premium apprenticeship is not touched on Descriptions of the various technical colleges and schools in the kingdom is given, but we regret to see that the length of description is almost in the inverse proportion to their practical value. The list of firms who accept premium apprentices is given, with some details of the course of instruction offered, but here again there has been no discrimination. In fact, although the printing and illustrations are good, the lack of originality and the wholesale use of cuttings from descriptions written by interested parties militates against the value of the book.

THE HIEATZMAN MAGAZINE FUSE-BOX AND KNIFE-SWITCH.

Quite a novelty in electric apparatus, whereby, it is claimed, a great saving of time, labour, and money is obtained, is brought out in the Hieatzman magazine fuse-box and knife-switch, which is sufficiently shown in the illustrations herewith to be readily understood. For general

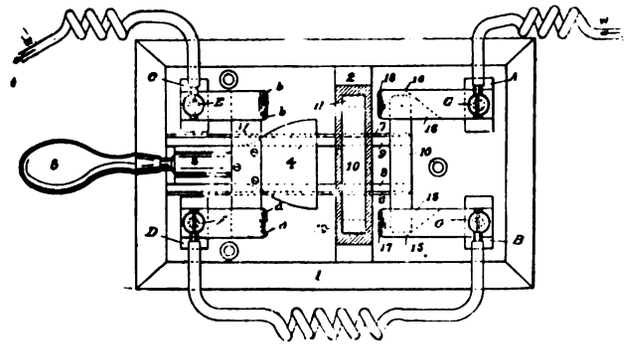

FIG. 1.

use a modification of this form will be constructed that will operate with even greater practical results—*i.e.*, a centrifugal, instead of a reciprocating, movement of the handle will be employed, as contacts can be more instantaneously made and broken with such construction. Fig. 1 is a top plan view. Fig. 2 is a view in elevation, part half-sectional.

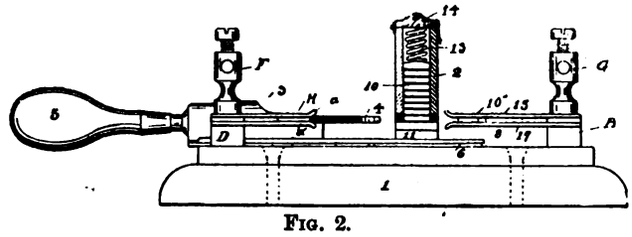

FIG. 2.

Referring to the illustrations: 1 is a base block of any suitable non-conducting material—the terminals, A G, B G', D F, and C E, are fastened one at each corner thereto; 2 is the magazine fuse-box; the plunger-block, 3, with its extending blade, 4, and operated by the handle, 5, has a reciprocating movement in the grooves, 6 and 7, which are formed by the rabbets, 8 and 9. On the top of the plunger-block, 3, is also fastened the switch-blade, H.

The magazine box, 2, has studs or small inward projec-

* From the *Electrical Review* (New York).

Digitized by Google

tions, 11 and 12, which keep the fuses, 10, from passing straight through, and with the concert action of the spring, 13, hold the fuses, 10, always in position. *a a'*, *b b*, 15, 17 and 16, 18 are the fingers of the various terminals to which they are affixed. The fingers 17 and 18 are constructed with projections, 15' and 16', on their inner sides.

The operation of the device is extremely simple, and can be readily understood. With the switch-blade, H, and the fuse, 10', in position between their respective terminals, the circuit is closed and the flow of the current is uninterrupted. Should the fuse "blow," thereby breaking the circuit, the insertion of another fuse is accomplished in the following simple manner: Push the handle in, which at the same time moves the plunger-block forward. This movement withdraws the switch-blade from between its terminal fingers; the extending blade strikes the lowest fuse within the magazine box and moves it forward into position between the fingers of the respective terminals for its reception. The end or ends of the burnt fuse are also at the same time by this movement forced from the terminals by the angles on the inside projections of the terminal fingers, 17 and 18. Withdrawing the handle again sharply brings the switch-blade back into position—in contact with its respective terminals—thereby completing the circuit again, and accomplishing in five seconds, it is claimed, that which, with apparatus now in vogue, requires from five to ten minutes.

The magazine fuse-box is not necessarily an adjunct of the knife-switch. It is independently operative with any kind of switch.

A METHOD FOR THE DETECTION OF WEAK DYNAMO FIELDS.*

BY BUCKNER SPEED.

The cotton covering of the wire wound on dynamo fields is subject to deterioration from three principal causes—slow carbonisation due to heat, oil from the bearings, and insufficiently baked shellac. These changes in the insulation of the wire allow the current to pass from layer to layer of the wire instead of all passing through the wire itself, and the field may thereby be greatly weakened, and yet show no ground from the field wire to the field core. The only cure for such weakening is to rewind the spool with new wire.

The spool or spools requiring rewinding may usually be determined with ease if the resistance of each spool be taken when first received from the factory. If, however, the original resistances cannot be obtained, and there is no certainty that the coils all had equal resistances when wound, the faulty coil may be determined as follows:

Measure the resistance of each spool with a Weston voltmeter and Weston ammeter, using currents of various strengths; thus in the measurement of an arc machine the field wire would be connected in series with a Weston ammeter and adjustable resistances for varying the current, which could be supplied from a constant potential generator, for example. The drop across each spool would then be taken with a Weston voltmeter, when the current is held steadily at one ampere, then at two amperes, then at three, and so on up to the normal current, say 10 amperes. If the wire covering is in good condition, the resistance of the spool will of course be constant for all currents, or rise slightly, owing to the field becoming warm. But if the spool be "green" from not having been baked, or if it has become soaked with dirty oil, its resistance will be about constant for the weaker currents and will abruptly decrease upon the application of the stronger currents. The writer has measured fields in which this decrease in the resistance of the coil was as much as 20 per cent.

In case of a dry carbonised field the resistance, when hot, will be either less than when cold or it may remain about the same, or even rise slightly, but in the last case the rise in resistance with heat will be much less than the rise that is caused by the temperature coefficient (0·4 per cent. per degree C.) of the copper.

The writer has had occasion to use the above method on a number of dynamos which showed evidence of weak fields, and it has never failed to correctly indicate the weak spool. Appended is a specimen of one of these tests. The spool was unwound and the wire found to be in a very bad condition, the cotton insulation being saturated with oil and coloured green with verdigris; there were also large black spots of carbonised and oily wire covering as large as one's hand. Upon rewinding the spool the resistance became constant, as shown in the second table.

ARC DYNAMO No. —.

9 80	67·0	6·83

After Rewinding.

2 9	20·9	7·20
5·6	40·3	7·20
8 5	61·0	7·18
9 3	67 0	7·20

For the successful use of this method several points are to be noticed. The Weston instruments are to be in the best of condition, newly calibrated and working without any sticking of their pointers. The instruments are to be removed a very considerable distance from any magnetic influences that will cause erroneous results. The measurements must be taken when the current is steady, readings taken while the current is varying being of no value. The readings on the meters must be large enough to enable an accuracy of observation of at least 1 per cent. To save the voltmeter from injury, its contact button must always be released before breaking the current in the field.

* From the *Electrical World* (New York).

PARALLELING OF ALTERNATORS.*

BY ROBERT HAMMOND, MEMBER.

(Concluded from page 299.)

Question 15.—When running in parallel, what is the synchronising current? How is this registered?

With Iron in Armature.

Altrincham.—(M. E. S.) None when the excitation of each alternator is properly adjusted.

Burton.—(L. and L.) Cannot say, as alternator ammeters swing about too much when running in parallel to be read with any accuracy.

Dublin.—(E. C. C. and L. and L.) There is practically no loss in synchronising current if engines govern properly. The amount is too small to be registered.

Halifax.—(E. C. C.) Average about two amperes. Excess of alternator ammeter over circuit ammeter.

Leeds.—(E. C. C. and L. and L.) When the ammeter needles on the dynamo ammeters are steady for a few moments, there is a very small difference between the circuit and the alternator meters—three or four amperes on the small dynamos, and about 10 amperes on the large and small together at full load. It is difficult to say what the synchronising current is.

Newport.—(L. and L.) The synchronising current at full load is very much smaller than at lighter loads, averaging 1 2 heavy, 2·5 light amperes.

Portsmouth.—(Ferranti and Parsons.) Cannot read any.

Salford.—(Hopkinson.) About five amperes at full load and at no load.

Southport.—(Mather and Platt.) About three amperes.

Without Iron in Armature.

Bristol.—(Siemens.) The synchronising current is too small to be appreciable.

Bournemouth.—(Mordey.) There is rarely any perceptible excess. The sum of the mean of the machine ammeters is always very close to the main ammeters' indication.

Cheltenham.—(Siemens.) Synchronising current is always less than one ampere.

Coatbridge.—(Mordey.) Synchronising current is at all times excessive.

Hampstead.—(Siemens.) The synchronising current is not detectable on the ammeters between the large-size alternators.

* Abstract of paper read before the Northern Society of Electrical Engineers.

Digitized by Google

With the 20-kilowatt alternator a current of three to five amperes passes. This will be rectified by inserting a flexible coupling.

Hanley.—(Mordey.) Varies from 6 to 20 per cent. We have an instrument on each alternator, and the sum of these in parallel exceeds the instruments on circuit-boards.

Prescot.—(Two Brush, two Ferranti.) About one ampere each machine; but the synchronising current depends on the care exercised by the attendant.

Sheffield.—(Brush and Ferranti.) Ordinarily two to four amperes.

From the above it would appear that the advantage lies with II. type, if one may treat as exceptional the statement from Hanley of a 6 to 20 per cent. synchronising current.

With regard to the next question, No. 16, it is a well-known experience in electricity supply works that occasionally the load, especially in the event of a sudden darkening of the sky, comes on so rapidly that it is a matter of the greatest importance to throw on additional plant as rapidly as possible. In my "alternating works" specifications I always stipulate that "the time taken to speed up a set of plant lying idle, but with the cylinders warm, and to put into parallel with a plant running fully laden, not to exceed two minutes." In my list of supplemental questions it will be remembered there was one to elicit the time actually taken in practice, but unfortunately up to the time of writing very few replies have come to hand, but they show that ordinarily my limit is not far exceeded.

It occasionally, however, happens that this excellent promptitude does not occur when it is most needed, with the result that the "moment" is lost, and the work of hitting-off synchronous speed has to be repeated. If pressed for time, the switchboard attendant may desire to expedite matters by plugging in with the alternators not exactly in phase. In practice this may, I think, be more safely indulged in on a rising than a falling E.M.F., but it is important to note whether different types of machine show any difference of behaviour on being so roughly treated. Here are the replies which I have received on this head:

Question 16.—Can you connect into parallel if the alternators are a little out of phase?

It would appear that both types stand this rough usage equally well: indeed, according to the Deptford experience, they prefer to begin their united life with a slight quarrel. It is here that the lag set up by self-induction plays an important part. By self-induction is simply meant the well-known action owing to which the current produced in a circuit lags behind the E.M.F. given by the armature of the machine. The Bristol answer is as follows: By paralleling through impedance, successful parallels have been made when the machines have been crossing phase about 120 times a minute, and on one or two occasions have been paralleled when running in reverse phase, and have pulled round without further mishap.

Doubtless the majority of those present this evening have studied the paper which Dr. John Hopkinson read on "Electric Lighting" before the Institution of Civil Engineers in 1883. He there showed that theoretically the conditions which caused two alternators to give out no current when connected in series were identically those which enabled them to run perfectly in parallel. Unless, therefore, there is any outside disturbing cause, the tendency of two machines put in parallel out of phase is to get into perfect phase and pace.

With regard to outside disturbing causes, it is evident the more give there is in the driving power the more readily they will fall into step. Belt or rope driving, therefore, has always seemed to me more likely to ensure perfect paralleling than direct driving. The facts, however, here set forth, obtained from works driving under the most varied conditions, appear incompatible with that theory, and only last month I was glad to find that at Ayr the newly-erected Siemens flywheel alternators, running at only 96 revolutions per minute, ran perfectly into parallel.

Question 17.—Have you ever known an alternator get out of step, due to any cause, while running in parallel? If so, what was the result?

With Iron in Armature.

Altrincham, Ayr, Dublin, Eastbourne, Halifax, Leeds, Newport, Portsmouth, Southport, Tunbridge Wells, Woolwich, and Woking all answer "No."

Blackpool.—(E. C. C. and L. and L.) Yes. When 100-kilowatt (L. and L.), 50-kilowatt (E. C. C.), and 100-kilowatt (E. C. C.) were running parallel. Jackcording over to change circuits, a jackcord was reversed and short-circuited the three dynamos. Voltage of all dropped; on withdrawing plug the alternators tried to take load again, but were out of step; 100-kilowatt (L. and L.) was switched out and the other two rose up again, pulling themselves into parallel.

Without Iron in Armature.

Bolton, Bristol, Bournemouth, Cardiff, Cheltenham, Chelmsford, Deptford, Exeter, Hampstead, Huddersfield, Kingston-on-Thames, Prescot, Sheffield, Sunderland, and Worcester say it has never occurred.

Coatbridge.—(Mordey.) Yes. Result was serious damage to two alternators concerned.

Hanley.—They will get sufficiently out of step to growl alternately against one another, due to bad governing of engines, causing wave of sound as per switch.

Larne.—(Mordey.) Yes, when running at very low speed; result, heavy alternation of current between alternators.

Yarmouth.—(Crompton-Brunton.) Not with a three-crank engine; have seen it occur at other stations with two-crank engines.

Mr. Hesketh's (Blackpool) quota is most interesting, as it shows, *inter alia*, how readily two machines of identical wave curves get into parallel under the most trying circumstances. The replies show that in not a single case in the kingdom have steam-driven alternators dropped out of step in their regular work, as, of course, one must consider the short-circuit described by Mr. Hesketh as a matter of rare occurrence and quite outside the range of regular working. With regard to Coatbridge, the data were supplied when the works were driven by gas-engines, and the testimony is valuable as demonstrating the unsuitability of gas-engines for driving alternators which have to run in parallel.

Question 18.—Will the alternators run equally well in parallel at any load?

The only thing I find to remark upon is the statement that the alternators at Huddersfield run best at three-quarter load. In my opinion alternators that are supplied to run in parallel should run best at their full load, being, however, capable of carrying an excess of 10 per cent. without undue heating in order to give a margin in case of the outside load rising with undue rapidity.

Question 19.—Do you employ a separate exciter to such alternator?

Question 20.—If so, do you run the exciters in parallel as well as the alternators?

Setting aside a somewhat ambiguous "sometimes" of Chelmsford, it appears that out of 34 works only 12 works use "omnibus" excitation. I appreciate to the full the advantage arising from excitation which does not vary in potential by a variation in speed of the alternator; but to secure perfect safety in parallel running, I think that separate excitation, in spite of Mr. Rider's emphatic "Certainly not," is to be preferred.

Question 21 I propose to deal with last. The answers to Questions 23 and 26 speak for themselves.

Question 23.—Do you always parallel with stop-valve wide open and then leave the plants on the governors?

[We have left these answers out, as the next question elicits practically the same information.—ED. *E. E.*]

Question 26.—Please roughly describe your method of paralleling.

Altrincham.—(M. E. S.) Control speed of plant being put into parallel by stop-valve of engine. When in synchronism and volts adjusted for load, close auxiliary paralleling switch through small fuses or self-induction coil, then close main switch, open stop valve, and adjust excitation for load as required.

Ayr.—(Siemens.) The second engine is run up to equal speed on its governor, and the plug inserted when lamp shows the phase to be correct.

Burton.—(L. and L.) By running up the engine steadily on the stop-valve we can put the machines in parallel without the slightest blink in the lights.

Dublin.—(E. C. C. and L. and L.) Engine run up to speed. Voltage set 3 per cent. higher on incoming alternator speed adjusted to synchronise and plug inserted. In an emergency the phase is caught as the engine is coming up to speed.

Halifax.—(E. C. C.) Run up to speed with stop-valve nearly closed; adjust volts of incoming machine rather higher than 'bus bars; synchronise and put on full steam, and slightly raise volts of new machine; then make final adjustment of load by hand expansion gear.

Leeds.—(E. C. C. and L. and L.) On three engines we parallel on stop-valve, and on other three we have stop-valve wide open when paralleling and adjust governor, but immediately after synchronise the stop-valves are all thrown full open and the engines run on governors.

Portsmouth.—(Ferranti and Parsons.) Fresh engine and alternator are run up to speed, then alternator is excited, volts being kept slightly in excess of the 'bus bar. Speed is controlled by the throttle, relative speed being determined by the optical effect on the field magnet produced by an alternating arc. Selection for switching-in is usually made with the speed of the fresh engine rising. A couple of lamps and a voltmeter are employed in the usual way for phasing. After switching on, the load is divided by adjusting the governors. It is in contemplation to phase the connecting-rods, as well as the alternations, by means of a belt.

Bristol.—(Siemens.) The incoming machine is first connected to the synchronising 'bus bars by means of plugs, and from

these bars through two choking coils in series to the two lower contacts of the synchronising switch and to one primary winding of the synchronising transformer. The machine on mains is connected to the two top contacts of the synchronising switch and then to the transformer by means of two small switches. The secondary winding of the transformer is connected to a lamp and Cardew voltmeter in series. When the synchronising switch is in, the machines are in parallel through light fuses with the two choking coils. When the ammeter needles remain steady, the choking coils are short-circuited and the machine switch put in.

Bournemouth.—(Mordey.) A 50-volt secondary fed by a transformer across 'bus bars is put into series with a 50-volt secondary fed by a transformer on alternator armature, and a lamp for engine-driver and voltmeter for engineer; switching supplied in usual way. Engine is run up to speed on the stop-valve, machine voltage equalised to that of 'bus bars by use of a resistance in exciting circuit, and machine switched in when a steady co-phasedness is shown by synchronising voltmeter. The machine thus put in contributes no current to 'bus bars until the steam admission is increased, when it takes up its share of the load.

Kingston-on-Thames.—(Siemens.) The new machine is run up until its voltage, as shown by the machine voltmeter (common to all machines through a multiple D.P. switch), is similar to the voltage on the omnibus bar. It is then synchronised by means of a synchronising lamp and put into parallel. The E.M.F. of the machines can be regulated either by their speed or by means of the field-magnet resistance switches. These can be worked separately for any machine, or can be worked together when the machines are running in parallel by means of a worm gear.

Worcester.—(Mordey.) The field of incoming alternator is excited off low-tension 'bus bars (common to all four alternator fields), and exactly balanced by means of adjusting resistance in field circuit to allow for difference of temperature of field coils. Incoming alternator then speeded to 430 revolutions per minute as shown by tachometer, and a synchronising lamp shows exact moment to operate the D.P. switch and connect to high-tension 'bus bar. The machine is then given load by means of special adjustment on engine governor.

The details of those alternators obtained by Mr. Hammond are given in Table A. In the other cases the details did not include much beyond the output and speed of the machines.

I am sorry that the data set forth in Answer 21 is not more complete, as I am inclined to think that, given a well-built alternator mechanically and electrically, the secret of perfect parallel running is to be found in perfect turning moment, and perfect turning moment depends upon flywheel energy, steadiness of drive added to good governing. With regard to the last, my practice is to stipulate governors to run from full in to full out with 5 per cent. changes of speed, also an adjustable weight to vary speed by hand, 5 per cent to be provided. The governing arrangement such that the speed shall not vary more than 5 per cent. with 100 per cent. of the load thrown instantaneously off and on, with the stop-valve wide open, nor more than 2½ per cent. when changing over from condensing to non-condensing. With regard to flywheel energy, I may mention that in a recent specification I indicated 35 tons as a minimum for the weight of the field magnets of the alternator acting as a flywheel, with a centre of gravity at a radius of 10ft., and normal speed of the engine 100 revolutions per minute. With regard to three-crank *versus* two-crank engines, I should be inclined from the point of view of parallel running, to give the preference to the former, provided that good governing could be relied upon. At the same time, I must confess that the excellent results achieved last year at Leeds with rope-driven, slow-speed horizontal engines confirms me in my preference for that type of plant when space is available and coal is obtainable at a reasonable figure. I should certainly give it the palm so far as smooth running is concerned.

No paper on parallel running would be complete without pointing out that the lower the periodicity the easier the paralleling. I have already instanced the excellent paralleling at Ayr with a direct-driven plant running at 96 revolutions, whereas at Leicester it is a matter of common knowledge that perfect paralleling has so far not been attained by a direct-driven plant running at somewhat similar speed. May not the reason be that in the former case the periodicity is 60 and in the latter 100? It would be a great boon if there could be some standard periodicity settled upon as there has been practically a settled voltage for incandescent lamps.

INSTITUTION OF ELECTRICAL ENGINEERS.

The conclusion of the discussion on Thursday week on Mr. Addenbrooke's paper on high-voltage lamps and their influence on central-station practice could only be given very briefly in our last week's issue. The following gives at somewhat greater length the remarks of the speakers who succeeded Mr. Stearn.

Mr. Rose, in order not to prolong the debate, would only remark that he had found very little trouble in the manufacture of the higher-voltage lamps. His firm had supplied them to Wolverhampton, Manchester, and Bradford.

Mr. Snell said that at St. Pancras they were running lamps at 220 volts, and had had very little trouble with them; in fact, their consumers hardly knew the difference between the 200 and 100 volt lamps. If any trouble did occur, it was at the holder. With regard to steadiness of voltage, the Board of Trade allowed a 3 per cent. deviation. With 440 volts, it would be easier to maintain a less percentage deviation at the lamp terminals than with 220 volts.

Mr. Robertson said that, so far as his experience went, there would be no difficulty whatever in converting the whole of his firm's manufacture to 200 or even 300 volt lamps if it were required.

Mr. Geipel proposed to hand in his remarks for publication,

Digitized by Google

He, however, contended that Mr. Addenbrooke's figures showed no advantage over the alternating-current system so far as first cost was concerned. The £60 allowed by him for the distributing mains on the 200 volt system was sufficient to cover the entire cost of the alternating station on the 100-volt system; and this with the station outside of the populous district, while Mr. Addenbrooke had his in the centre of the town It was a very great advantage to have the central station outside the town Not only was the site cheaper, but coal was more easily got and frequently water for condensing was available He thought there was no one in the room who would deny that 50-volt lamps could be run at a higher efficiency than 100-volt lamps, and 100-volt lamps at a higher efficiency than 200-volt ones. A great deal had been said about the life of 200-volt lamps, but in those trials what efficiency had they been run at? If a lamp was run at six watts, it would last for ever. Also, he would like to ask Mr. Stearn why he did not use his new method of strengthening the filament for making good 8 c.p. 100-volt lamps. With reference to the experience of Mr. Gibbings at Bradford, he would suggest that the consumers had not yet had their accounts, and that their satisfaction only referred to improvements in the pressure

Mr. Epstein, speaking on the subject of accumulators, said the figures given in the paper were borne out by his own experience. He thought the last word had not been spoken as to cheapening accumulators, and that further advances might be expected in this direction

Mr. Campbell Swinton wanted to know what the term "candle" meant in the efficiency tests. There were the English, French, and German candles, and they differed He was not referring to the difficulty of measurement, but simply to the standard adopted, as to which it was essential there should be uniformity.

Mr. W H. Patchell thought the consumer would expect to have his 200-volt lamps at the same price as he had paid for 100-volt lamps. At the present moment, if that were so, the company would have to supply them at a loss. With reference to what had been said as to the need of a better 8-c.p. 100 volt lamp, he himself had had no trouble with them, and he did not think that where there had been any trouble or difficulty with them they could have been run at a steady voltage.

Mr. Handcock said little had been heard on the subject from the consumer's side of the question. What was wanted was to know the efficiency of lamps at 200, 100, and 50 volts, and their efficiency at the end of 1,000 hours. So far as his experience went, he felt that at 100 volts the limit had been about reached. Complaints had been continually received about lamps, which really were due to unsteady voltage for the same lamps did exceedingly well when the voltage was regular. In speaking of the necessity of a steady voltage, the inventor of the incandescent lamp (Mr. Swan) had hit the right nail on the head. He (Mr. Handcock) thought the right thing was done by the New York company which included the cost of lamps in its rate and tested them in its laboratory. Again, he would like to ask whether, where the higher voltage was adopted it was the intention of the supply companies to charge for the current at such a rate that the consumer got the same amount of light for his money as he would with 100 volt lamps, because the change from 100 to 200 volts appeared to imply a change from a three-watt to a four-watt efficiency. His experience also showed him that at 220 volts there was liable to be trouble with the fittings even if these were the best that money could buy, but this could doubtless be overcome if the makers would remodel their patterns.

A suggestion was made that in certain cases it would be desirable, if it were possible to have lamps of less than 8 c p., and no other speaker rising, a written communication was read from **Mr. Baynes** who was unable to be present. This was mainly a recapitulation of the circumstances under which the change was made at Bradford from 115 to 230 volts. There were already over 15 stations in the United States working at the double voltage, which was a striking example of the much more cautious way in which a change was adopted in this country than in America. He considered that in his figures Mr. Addenbrooke had been unnecessarily liberal with his copper. With reference to the manufacture of lamps of higher efficiency at 100 volts, Mr Baynes pointed out that these lamps could be used on a 200-volt system wherever they could be run two in series—for instance, in all cases of shops and large rooms. Where the wiring was well done, there was less risk of fire in the higher-voltage system because the fuses were lighter. No trouble had been experienced with the switches. He preferred however, conductors in close proximity, and not in casing at arcing distance apart.

The **President** (Dr. Hopkinson) said there was time for him to make a few remarks as to their experience at Manchester At the town hall there they were working at 400 volts, for they had taken all five wires into the building, and were running as many as four lamps in series. In other buildings they had three wires, and ran lamps two in series, and they had had no trouble. As to leakage, it was admitted that there was some from the negative terminal as the middle wire was put to earth. That arose from bare copper being used. The leakage did not cause any inconvenience, though there was a certain loss of power. Bare copper was found so convenient that its use was being extended By the use of accumulators very great facility of regulation was obtained, since the limits were brought within that of one cell.

Mr. Addenbrooke said that such a very large number of points had been raised that he would not attempt to answer them that evening, but would send in his reply for publication. He must, however, acknowledge his indebtedness to Mr. Crompton for the help he had received in preparing his paper, and also to Mr. Scott, Mr. Callender, and Mr. Epstein. In the course of a conversation with Mr. Swan he had learned that the idea that there was a great demand for 8-c.p. lamps was a mistake. These did not really number much more than one-quarter of the 16-c.p. lamps. It was, he thought, a great pity that the practice should be continued of counting lights on the basis of an equivalent of 8-c.p. lamps, instead of 16-c.p. lamps. That was a practice that dated back to the early times, when people wished to show a large number of lamps on their circuit. It had also occurred to him as a curious thing that they had never had an intermediate lamp, say, at 150 volts, on the market. Such a lamp would have been useful for lighting factories, and they could be used in new installations and on alternating systems. Lamps at 150 and 160 volts were used in Austria, but here it appeared the change was to be made at one leap. In Edinburgh, Prof. Kennedy was going to change to 230 volts. Wandsworth was to have the double voltage, and Mr. Shoolbred had told him that Birkenhead was to have it. He was glad to have had the speeches of so many lampmakers, because engineers, as a rule, knew little of lampmaking. They did not wish to press hardly on the lampmakers, and, if there was any special difficulty, if the makers would tell the engineers what it was the latter would endeavour to get round it There was no doubt that the fluctuations of voltage were much greater than central-station authorities liked to acknowledge, but he thought that 200-volt lamps were less affected by a slight change in voltage than were 100-volt ones. He might mention a case that had occurred in testing some gas-engines The voltage had run up to 300 volts and the filaments had bent over like a piece of red-hot wire, but unless they happened to touch the glass they did not break. It was, of course, simply a mistake to suppose that the life of a lamp with two filaments was half that of a lamp with one. The life was simply that of the filament which went first. Mr. Addenbrooke then defended his figures from the remarks of Mr Geipel, and remarked that he really might have made them much more favourable, but had preferred to take outside figures. In many cases of alternate-current stations Mr. Geipel's figure of £60 per kilowatt was much exceeded Other remarks he would hand in.

At the close of Mr. Addenbrooke's reply the usual votes of thanks were passed, and the meeting adjourned to March 26.

MANCHESTER ASSOCIATION OF JUNIOR ENGINEERS.

The members of this society met on Saturday evening, the 7th inst., at their rooms in the Central Schools, Deansgate, to hear Mr. Albert Battersby (of the Manchester electric light station) read his paper on "Electricity Generating Stations," the president, Mr. Thomas Jones, M.I.Mech.E., in the chair.

Mr. BATTERSBY said that on January 1, 1896, there was a total of 139 electricity supply stations in this country supplying electrical energy. The total amount invested in this manner amounted to over eight million pounds, and this sum had been spent almost entirely for the supply of electric light. Little attention had been paid to supplying current for motive power, which was rather surprising, as it would find a good day load; and if electrical energy was sold at one penny per horse-power hour a profit would be made, and it would most certainly, in the author's opinion, be generally used for small powers. Reference was made to the modern electric lighting steam-engine, which must govern well at all loads from zero to full, and the governing must be prompt and sensitive. The speed of the engine must be sufficiently quick to make the governing prompt; the valve gear should be as simple and strong as possible, so as not to get out of order, and the valves set so as to work economically with an average load. A moderate-speed engine was recommended by the author, say, between 70 to 180 revolutions per minute. A full description of the boilers in use at the various electric light stations was next given, and the author spoke strongly in favour of the Lancashire boiler on account of its simplicity of construction, immunity from repairs, and its large steam and water spaces. Forced-draught apparatus was not necessary, in the author's opinion, except for the burning of poor fuel. Mechanical stokers, if of the "coking" type, were an advantage if there were more than four boilers. The author advocated the building of generating stations on the outskirts of towns so as to be capable of great extensions, as the majority of stations running would be altogether too small in a few years' time. High-tension alternating-current supply would be the most suitable if the area was a scattered one. Alternating-current arc lamps were not so good in light-giving qualities compared with continuous arcs. Another objection to this system was that a good self-starting alternate-current motor was not yet available, so that in a town where there was likely to be a demand for motive power a continuous-current supply must be adopted. A full description was given of the Manchester electric light station, for the illustration of which Mr. Wordingham, the city electrical engineer, had kindly lent apparatus, instruments, etc.

The lecture throughout was illustrated by a large number of diagrams and drawings, and at the conclusion a hearty vote of thanks was passed to the author for his interesting paper.

THE PHYSICAL SOCIETY.

At the ordinary meeting, March 13, Prof. Carey Foster (vice-president) in the chair,

Mr. J. H. Reeves read a paper on "**An Addition to the Wheatstone's Bridge for the Determination of Low Resistances.**" The apparatus described can be used for measuring the resistance of metre lengths of wires of low resistance, the only additional apparatus required being a sensitive galvanometer, a Post Office form of resistance-box, and a metre bridge. It differs from the ordinary Kelvin bridge in that, instead of balancing by varying the length of the standard wire between the two contacts, the distance between these contacts is maintained constant, as is also the length of the wire which is being measured, and a balance is obtained by altering other resistances in the network. The author has made a number of tests which show that by his arrangement the resistance of metre lengths of copper wires between the limits of No. 22 S.W.G. and a stranded cable of seven No. 16's can be determined with an accuracy of 0·1 per cent. Mr. Reeves also read a note on the exact value of Matthiessen's standard.

A communication from **Prof. A. Gray** stated that the author had in his arrangement combined the fixed standard employed in Matthiessen and Hocking's modification of the ordinary bridge with the greater celerity of working arising from the smaller number of operations to be performed when the Kelvin bridge is used. Prof Gray thought that he, and probably others, had used a method similar to that of Mr. Reeves's, but that the paper was of great utility, since it showed how time may be saved and existing apparatus utilised.

Prof. Ayrton said that the advantage of the method described lay in the fact that it was independent of the resistances at the contacts In Carey Foster's method, however, the coils had to be interchanged, and inaccuracy might be introduced owing to the varying resistance of the mercury contacts. Unless the mercury-cups and the copper plates at the bottom were cleaned every day and the contacts reamalgamated, the resistance of the mercury-cups was very variable With regard to the question of Matthiessen's standard, it was to be remembered that the specific conductivity of copper had been steadily increasing. This increase was particularly noticeable in the copper prepared by the Elmore process, where during the deposition of the metal an agate burnisher is kept continually passing over the surface. Fitzpatrick had explained the rise in the conductivity of copper by supposing that the density of the copper now supplied was greater than that of the copper used by Matthiessen, and this explanation had seemed quite satisfactory. Mr. Reeves's experiments, however, have conclusively shown that this was not the true explanation ; it was now possible to obtain copper in large quantity having a conductivity of 103 on Matthiessen's scale.

The Chairman explained how, when using his method, the accuracy of the result depends, not on the elimination of the small resistances at the mercury-cups, but on the constancy of these resistances. Matthiessen and Dr. Russell found that the specific gravity of copper was apt to be low on account of the presence of dissolved oxide, and they were the first to pass hydrogen gas through the molten metal to remove this oxide.

Mr. Appleyard gave a simple diagrammatic sketch of the author's arrangement, and also pointed out that better results would probably be obtained with a galvanometer of one or two ohms resistance.

Mr. Campbell said that it ought to be definitely settled whether Matthiessen's standard was the conductivity per unit volume or per unit mass. Since copper was always bought by weight, he, as a practical man, strongly advocated the adoption of the mass conductivity ; further, in this case, the measurement of the specific gravity would be avoided.

Mr. Reeves having replied, a communication by **Mr. Puluj**, on "**Cathode Rays,**" was read by the **Secretary**.

Mr. Puluj contributed some Röntgen photographs taken by means of a form of Crookes tube which he had described in a memoir published in 1889. With this tube he has succeeded in obtaining impressions with exposures of only two seconds. Mr. Puluj considers that the particles of matter torn from the cathode, which convey negative electrostatic charges, by impact on the glass walls or on screens, equalise their electric charges, and in this process call forth, not merely a disturbance of the material molecules, but also of their ether envelopes Each portion of the glass or screen bombarded by the cathode stream becomes the starting point of ether waves, which, according to their oscillation period and oscillation character are either visible rays (phosphorescence) or invisible Röntgen rays The oscillations of the invisible rays may take place in a longitudinal direction, but no convincing argument had up to now been brought forward to support this view.

The **Secretary** also read a note on "**Permeability to Rontgen Rays,**" by **Messrs. Ackroyd** and **Knowles**. The authors have exposed a plate on which a number of pieces of metal, oxides, and sulphates were placed to the Röntgen rays in order to see whether the permeability of bodies to these rays depends on the atomic or molecular weight of the body. In each case it was found that the opacity increased with the molecular weight.

Mr. Blakesley said that he considered the Röntgen rays to be the propagation of electrostatic strain through space. With reference to the non-refrangibility of these rays, he had observed in one of the photographs exhibited by Mr. Swinton a dark line at the edge of the shadow of a wooden pencil which might have been due to the refraction of the rays by the wood. Mr. Blakesley had, however, found that this line was due to the varnish on the pencil. Some Röntgen photographs of quartz and ebonite rods, not only did not exhibit these dark lines, but there was a very slight indication of a bright line just on the edge of the shadow, which would indicate that the refraction of these rays was less in the rods than in the surrounding medium.

Mr. Edser exhibited some photographs taken with Mr. Jackson's form of tube, in which a concave cathode is employed Mr. Edser said that the whole of the tube on the cathode side of the anode plate phosphoresced. so that the Röntgen rays seemed to partake of the character of diffused light.

Prof. Ayrton said Mr. Jackson had found that the cathode rays formed a parallel beam, and did not first come to a focus and then again spread out.

Mr. Blakesley described the tube used by Puluj in which a mica screen coated with green calcium sulphide is placed between the cathode and the anode.

Mr. Gardner said the phosphorescence of the inside of the glass had been shown by Lenard to be due to electricity travelling round the inside surface of the glass.

In reply to **Mr. Pidgeon**, the **Chairman** said that Captain Abney had found that if the film was mounted on a ferrotype plate no action took place.

Prof. Perry said that he, for one, was of opinion that the Röntgen rays were undulatory. Prof. Larmor had given an explanation which seemed to agree with the observed facts. This explanation supposed that the intermolecular spaces respond to vibrations of a certain frequency. The reason no refraction or diffraction effects had been observed, was probably because of the extreme smallness of the wave-length of the undulation.

After some further remarks the society adjourned till March 27.

COMPANIES' MEETINGS AND REPORTS.

W. T. HENLEY'S TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Friday last at the Company's offices, Martin's lane, E.C., Mr. Sydney Gedge, M.P., presiding.

The **Chairman** in moving the adoption of the report, an abstract of which has been given in this paper, remarked that it was a very pleasant duty he had to perform in moving the adoption of so satisfactory a report and balance-sheet. There had been times when the Board had had to meet the shareholders and tell them that the dividends they were looking forward to were still in the future Those times had now passed. They began by paying 5 per cent., which was increased to 6 per cent., and they now recommended a distribution of 8 per cent. upon a statement of accounts of such a character that some of the shareholders might perhaps ask why they did not propose to pay 10 per cent. They had transferred £5 000 to reserve, as against £2 180 last year, and they had written off for depreciation £1,964, as against £1,000 They had also expended about twice as much as usual on the maintenance of their works which were in first-rate condition. Their volume of sales had increased by nearly 47 per cent. compared with those of the previous year, and this had not been owing by any means to any large submarine cable work giving them a large profit, but to the steady growth of their general business The balance of profit and loss account was £18,942, which was increased by the balance brought forward to £27 567. As he had said they could have recommended a larger dividend, but, after full consideration, the Board had come to the conclusion that it would be far more to the interests of the shareholders individually and to the Company as a whole to strengthen the reserve fund by the amount he had mentioned, and to carry forward a large balance - £13,367 The amount owing by the Company was £17 525, while the amount due to them exceeded that sum by £42,841. In keeping a large sum of money in the hands of the Company he was convinced that it would fructify there at least as well as an extra dividend would in the shareholders' pockets ; for he need hardly tell them that having ready money in hand and plenty of it, the Company were able to make their purchases on much better terms than if they had to give acceptances. The gross profit on the trading of the Company last year was £36,967, which had been earned at an expense, including directors' fees, of £14 176, or about 38 per cent. In the case of another company in the same way of business he saw that their gross profit was earned at an expense of about 48 per cent , and, as the shareholders were aware, the larger the gross profits the smaller should be the percentage of fixed charges. He therefore believed that the Board would be commended for their economical management The capital of the Company was £100,000 in ordinary shares and £30 000 in preference shares bearing 7 per cent , but the holders of the latter had the option up to July 2 next of giving six months' notice to convert them into ordinary shares He believed that the conversion would prove advantageous to the preference shareholders, while it would certainly be beneficial to the Company should they ever require, for the extension of their business, to raise further capital by preference shares. He therefore hoped they would give those notices and that the conversion would be effected. In reference to the workmen's dining-room and lavatory at their works, he might mention that these had not yet been erected because the negotiations for the closing of Victoria road and including it in the works were not yet completed. They hoped, however, this would be done during the present year.

General Hutchinson seconded the resolution for the report and

Digitized by Google

accounts, and after some conversation, mostly of a complimentary characted, it was carried unanimously.

Resolutions were then carried for a dividend at the rate of 7 per cent. per annum on the preference shares and at the rate of 5 per cent. on the ordinary shares, making with the previous dividend one of 8 per cent. per annum free of income tax. The retiring directors and auditors were then re elected, and the proceedings closed with the usual votes of thanks.

OXFORD ELECTRIC COMPANY, LIMITED.

The general meeting of this Company was held last Friday at Oxford, Sir Henry Mance presiding.

The directors' report was as follows: "The revenue account shows a gross profit of £2,709. 8s. 3d. After providing for the full interest of 5 per cent. on the debenture issue and other interest, there remains £1,317. 9s. 4d., which, added to the amount brought forward from the previous year (£195. 4s. 8d.), leaves an available balance of £1,512. 14s. The directors recommend that a dividend of 3½ per cent be paid upon the ordinary shares, which will absorb £1,152. 11s., leaving £360. 3s to be carried forward to the next account. The running of the plant during the year has given entire satisfaction. Current has again been supplied to the public throughout the year without the slightest interruption. Since the last report 3,797 8-c p. lamps (or their equivalent) have been added to the system. On December 31 the number of lamps connected equalled 15,000 8 c p. lamps. Fifteen colleges are now connected to the mains, and the directors have every reason to hope that the increase in the number of lights during 1896 will be equally satisfactory. A new 150-h.p. engine and 100-unit dynamo of the same type as those already in use have been installed at the generating station and various additions made to the machinery and plant during the year. To provide for the anticipated increase in the demand for current, the directors are carefully considering the expediency of enlarging the works at Osney in accordance with the original design, and establishing additional sub-stations in various parts of the city. To provide for these extensions, the directors propose to issue 914 ordinary shares of £5 each. A new contract for the public lighting of the city has been entered into, the number of public lamps increased from 16 to 32, and the candle-power from 1,200 to 2,000 per lamp All the plant has been maintained in efficient order, and notwithstanding the high price of coal at Oxford, the expenditure of coal per unit of current delivered has been reduced to ·55d "

The **Chairman,** in moving the adoption of the report and accounts, said that at their last annual meeting he mentioned that the 1 per cent. they then paid on the ordinary shares was only an earnest of better things to come in the near future. He had that day to ask them to approve of the distribution of 3½ per cent on the ordinary shares. He was content to let the future speak for itself, but they could make a shrewd guess as to the probable requirements of the city of Oxford and the capacity of their works to meet those requirements. He did not presume to prophesy, but he could at least anticipate, and he might say that he had the highest opinion as to the future of the Company. They as directors might be permitted to congratulate themselves on the progress which had been made; at the same time they were not unmindful of the credit due to the system and to the whole staff.

Alderman Buckell seconded the resolution, remarking that the growth had been steady in the number of lights, and the current that had been supplied had been continuous, and the works had been conducted thus far without a single hitch or failure. He thought the history of the Company in this respect was almost unique in the history of electric companies in this country. They had, of course, the advantage of the experience of other companies, but they owed a great deal indeed to the system which had been inaugurated in the city, and a great deal also they owed to the efficient management of the Company by their chairman and by their engineer.

The resolution was carried unanimously.

BIRMINGHAM ELECTRIC SUPPLY COMPANY, LIMITED.

The annual meeting of this Company was held last week at Birmingham, Mr. H. Buckley presiding.

The **Chairman,** in moving the adoption of the report and accounts, a copy of which appeared in our last week's issue, apologised for the absence of Mr. G. S. Albright and Mr. J. F. Albright, members of the Board, who were abroad, and that of Mr. Holmes, the consulting engineer, who was unwell. The directors, Mr. Buckley said, were thoroughly satisfied with the progress of the Company during the past year. The issue of new shares to the amount of £50,000, authorised by an extraordinary general meeting, had been readily carried into effect. The premium was dealt with in such a manner that the item of preliminary expenses was wiped out of the balance-sheet, and further sums had specifically been placed against the cost of provisional orders. The reserve had been materially strengthened. The policy of reducing the price of light, which, of course, had materially affected their revenue at first, had been justified by the result. The loss in revenue had been overtaken by the increase in consumption, and the prospects for the current year, as shown by the returns for the first two months, were eminently satisfactory. They were not only getting fresh customers, but their present customers were increasing their consumption. The report of the Birmingham Old Library showed that last year, when the whole establishment was lighted by electricity, the cost, including repairs and renewals of lamps, was £75 9s 9d, against £77. 3s. 9d., the cost of gas for 1893. This result was attributed to the fact that the electric light was better distributed and could more readily be economised. The Birmingham Library was not the only concern in Birmingham that had had such an experience with the electric light. They had at the present time 20 miles of mains in the streets of the city, and there was a fairly steady increase both in the summer and in the winter consumption, while the increase in the number of lamps was quite steady.

Mr. J. H. Wilkinson seconded the motion, which was carried unanimously.

A dividend of 4 per cent was declared, and, in reply to a question, the **Chairman** said that they were unable to declare an interim dividend because during one half of the year their revenue was small as compared with that for the other half. Whether they would be able to do so in the future would depend largely upon the extent to which electromotors came into use in the city.

DOVER ELECTRICITY SUPPLY COMPANY.

The annual general meeting of this Company was held last week at Dover, Sir W. H. Crundall presiding.

The directors' report stated that on capital account the sum expended within the year amounted to £23,087. 19s. 8d, making with the expenditure of the previous year a total of £48,259. 1s. 6d. The revenue account for the year showed a loss upon the first nine months' working. This was largely due to the fact that the six months of lightest consumption—viz, from April till September—when the load was also abnormally light owing to the limited number of lamps then connected, were included, but in December the revenue about balanced expenditure and the directors believed that by the end of the current year the Company would be earning revenue in excess of working expenses. During the past year the generating station had been completed, the plant and machinery installed in complete working order, and the supply of current, commenced in April, 1895, was now continuously available by day and night for both lighting and power purposes throughout the whole of the main business streets, and in a considerable portion of the residential districts.

The **Chairman,** in moving the adoption of the report, said that no young company could expect to make a profit and declare a dividend on the first year's work. Their position, however, was most satisfactory, because, up to the present time, they had more than 5,000 8-c.p. lamps, or equal thereto, connected with their works. Having regard to the fact that with the present machinery they were only prepared to supply 10 000 8-c p. lamps, that position after the first 11 months' running was very good indeed. It showed that Dover had not been slower than other towns in adopting electricity and appreciating the great advantages to be derived therefrom. As to the cost of the current, the directors had seen their way to reduce that and to bring it almost down to the price of gas, and therefore they had done as much as could be reasonably expected, because they were giving a most luxurious light to the community. Gas spoilt the decorations of houses, and often injured health. If they saved their customers the cost of redecorating their houses, and gave a light that was pleasant and not injurious to health, it would be seen that in the long run electricity was the cheapest illuminant. Judging from the promises that the Board received, and the contracts entered into, they hoped soon to utilise the whole of the machinery—that is to say, that they would have equal to 10,000 8-c.p. lamps connected. When that occurred they would be in a position to declare a dividend. As to the prospect of having electric tramways at Dover, he believed that the whole town was in favour of electric trams, and the town would find it best in their own interests, and more economical to the ratepayers, to come to the Company for a price at which they could take current to drive the cars.

The resolution was seconded by **Mr. W. G. Lewis,** and after some remarks from **Mr. Van Tromp** on the subject of electric trams and motorcarts was carried unanimously.

EASTBOURNE ELECTRIC LIGHT COMPANY.

The annual meeting of this Company has been held at East bourne, Mr. J. G. Langham presiding.

The **Chairman,** after expressing his regret at the absence of Mr. George Boulton, the chairman of the directors, owing to ill-health, then moved the adoption of the report and accounts for the year ending December 31 last, and congratulated the Company on the business done. There had been an increase during the year of two arc lamps and 2,150 incandescents, making the total lights in circuit 37 arc and 14,206 incandescents for terms of 8 c.p. The revenue account showed a gross profit of £3,182. 2s., and, after adding £400 to the depreciation fund and paying debenture and other interest, they had £1,656 available for dividend. Last year they started a reserve fund with £300. To this they proposed to add another £300, making £600, and there would be enough not only to pay a dividend of 7½ per cent., the same as last year, which would absorb £798. 15s., but to carry forward £557. 5s. Last year the balance carried forward was £441. With the £400 added this year their depreciation fund amounted to £2,225. They had laid a new boiler in during the year, but regarding it as an addition to their plant—a necessary addition in consequence of the increased demand for the electric light—they would charge it to capital. Reviewing the history of the Company since its incorporation in 1882, the Chairman mentioned that the receipts in each successive year had been as follows: £1,140, £1,912, £2,611

Digitized by Google

(two years). £2,173, £3,497, £4,053, £4,539, £6,753 (a year and a quarter), £4 549, £5 216, £5,910, £6,713. In 1892 they paid their first dividend, 3 per cent.; in 1893 they paid 5 per cent.; in 1894 they paid 7½ per cent.; and this year they were in a position to pay the same amount. There were at present no less than 16 miles of pipes laid down in 11¼ miles of street in Eastbourne, and there were 11¼ miles of double cable and 3½ miles of single cable, making a total of 26 miles of cable in the town.

The motion was seconded by **Alderman Sutton** and carried.

Mr. Hollins was chosen a director in place of Mr. Sutton, who declined re-election.

ROCKHAMPTON GAS AND COKE COMPANY, LIMITED.

The directors' report submitted to the half yearly meeting held at Rockhampton, Queensland, on February 11, stated that a marked improvement had evidenced itself in the consumption of gas as compared with the preceding half-year, but the total quantity consumed is considerably below that of former years. The gas operations showed a profit of £1,926. 2s 4d. There had been a slight drop in the quantity of electricity supplied during the half-year. Adhering to the principle established from the date of the introduction of electric light into the Company's business, care had been exercised to avoid a too rapid development to avoid an unnecessary clashing with the gas interests. Owing to the small number of new installations, and the consequent reduction in the profit derivable from the sales of fittings, the electrical operations did not show as advantageously as for the preceding half-year. As several new electric light consumers had been added to the list, and the general expenses were likely to be considerably reduced, the prospect for the current half-year in this department was encouraging. To minimise expense, and to enable the electric light operations to be worked more economically, and also to secure a reserve of electrical energy, the directors were importing a large set of accumulators, and they expected these to be in operation towards the end of the current half year. The electrical operations showed a profit of £219. 10s., which had gone towards the payment of debenture interest amounting to £300, charged to the electric light operations, leaving a difference of £80. 10s. represented in the debit balance of the profit and loss account of this section of the Company's business. The net profit for the whole of the Company's business was £1,845. 12s. 4d., and from this the directors recommended the payment of a dividend at the rate of 7 per cent. per annum upon the ordinary shares and 9 per cent. per annum upon the preference shares, and carrying a balance of £183. 12s. 8d. to next half-year. The report is signed by Messrs. Henry Jones (chairman), F. Clewett (director), and William Spier (secretary and general manager). The usual accounts are appended, from which it appears that generating current cost £542, and sales of current realised £818. The reserve fund for maintenance of plant stands at £2,289 and there is also a small reserve of £291 available for equalisation of dividends. The total of the capital account is £61,771.

IMPROVED ELECTRIC GLOW LAMP SYNDICATE.

A meeting of this Company was held on Saturday at the Cannon-street Hotel, E.C., but the Press were not admitted.

LEGAL INTELLIGENCE.

ELECTRIC LIGHTING LANTERNS.

In the Chancery Division, before Mr. Justice North, on Friday, 13th inst., an application was made in the case of Clarke *v.* Sax on behalf of the plaintiff, John Farrand Clarke, for an interim injunction against Messrs. Julius Sax and Co., Limited, to restrain them from infringing the plaintiff's copyright in a registered design for lanterns used for electric lighting.

Mr. Swinfen Eady, Q.C., and Mr. Metcalfe (instructed by Mr. H. Stanley Sugden) appeared for the plaintiff, and Mr. Vernon Smith, Q.C., and Mr. Church represented the defendants.

It appeared that the defendants held a concession from the Corporation of the City of London to supply electric lighting to the Central Meat Markets, and that the plaintiff was the owner of a registered design invented by him for electric lighting, and that the defendants had used lanterns which were a colourable and obvious imitation of the plaintiff's lantern. The defendants contended that there was a difference between the two.

Mr. Justice North gave judgment for the plaintiff, and granted the injunction.

DOLBEAR'S PATENT.

At a sitting of the Judicial Committee of the Privy Council on Wednesday (present Lord Watson, Lord Hobhouse, Lord Davey, and Sir Richard Couch), the decision was given in the case of a petition for prolongation of letters patent granted to Mr. Amos Emerson Dolbear, of Somerville, Massachusetts, bearing date March 21, 1882, No. 1,368, for an invention of "Improvements in Electrical Cables."

Mr. Moulton, Q.C., Mr. Bousfield, Q.C., and Mr. J. C. Graham appeared for the petitioners, who were Mr. Amos Emerson Dolbear and the British Insulated Wire Company, Limited; Mr. Cripps, Q.C., Mr. Roger Wallace, Q.C., and Mr. A. J. Walter for opponents; and the Attorney-General and Mr. Sutton for the Crown.

The invention related to the insulation of electric conductors, and consisted in reducing to the smallest possible extent the contact between the conductor and the surrounding insulating material. The British Insulated Wire Company, Limited, became the owners of the letters patent in September, 1895. The petition stated that at the date of the letters patent—viz., 1882—there was little or no need for cables made according to the invention. Now, however, that large numbers of insulated wires for telephonic purposes were laid in the form of cables in troughs or pipes in the ground, and cables insulated according to the invention had been found to be of great value for this purpose. Owing to the above causes the invention did not come into any commercial use until quite recently.

Lord Watson pointed out that no effort was made to push the patent commercially until 1892. Their Lordships would advise her Majesty that the prayer of the petition ought not to be granted, and would direct that the caveators should have one set of costs.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Aberdeen.—The Corporation invite tenders for an additional engine of 300 h.p. at the electric lighting station.

Prague Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadrath, Prague.

Paris.—On April 9 there will be a limited competition at the Hotel de Ville for the supply of eight standards for the electric lighting of the Quai de Jemmapes and the Quai de Valmy.

Aston Manor (Warwickshire).—The Urban District Council require tenders for a high speed vertical engine and dynamo for the improved lighting of the baths. The estimate is £350.

Duisburg (Germany).—The Municipality require tenders before March 23 for the electric lighting work for their new swimming-bath. Particulars can be obtained for 2 marks (2s.) from the Stadtbaurath, Duisburg.

Elberfeld.—Tenders are wanted by April 20 for the supply of four engines and dynamos and 174 lamps, conductors, etc, for the Prussian State Railways Address, die Königliche Eisenbahn-Direktion, Elberfeld, Germany.

Halle-a.-Saale.—Tenders are required by March 24 for the supply of pine wood telegraph poles for the State Railways. Particulars at the office of the Konigl. Eisenbahn Direktion, altes Bahnhofs-gebäude, Halle a.-Saale.

Zamora (Spain).—Tenders are wanted by March 30 for the concession of the electric lighting of the town of Zamora for a period of 40 years. Particulars can be obtained from the Municipal Authorities. A security of 4,000 pesetas (£160) will be required.

Paris.—Tenders are required for the supply of pipes, tubes, and sheets in copper and brass for the arsenal at Haiphong (French East Indies), in two lots. Specifications and particulars at the Ministry of the Colonies, Paris, and at the Chambers of Commerce at Paris, Marseilles, Bordeaux, Nantes, and Havre.

St. Pancras, N.W.—The Vestry invite tenders for additional plant at the King's-road central station—viz, three engines, necessary dynamos, steam-pipe connections, switchboard, and other apparatus. Particulars are given in our advertisement columns Tenders to the chief clerk, 57, Pratt-street, Camden Town, N.W., by 12 noon on 26th inst.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and, if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Edinburgh.—Tenders are required by the Corporation for the wiring of the City Chambers. Specification, forms of tender, and plans of the building can be obtained at the office of the resident electrical engineer, 5, Dewar-place, Edinburgh, on deposit of £2 2s., which deposit will be returned on receipt of a bona fide tender. Tenders must be sent to Mr. Thomas Hunter, W.S., town clerk, by 10 a.m. on 28th inst.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, 13, Comeragh-road, West Kensington, W., where applicants can obtain a memorandum explaining the local conditions. The tenders will be opened and considered by the Municipality of Lima, which reserves to itself the right of selecting that which is most approved or rejecting all if it thinks fit.

Brussels.—Tenders are wanted for the supply of a large quantity of stores and fittings and apparatus (12 lots) for electric lighting. Specifications and particulars can be obtained at the

Digitized by Google

Brussels Bourse, and tenders must be in by March 25. In the various lots are included copper wire, commutator brushes, mica, cables, platinum wire, phosphor bronze, ebonite, arc lamp globes, incandescent lamps (various voltages and patterns), armoured cables, etc.

Shoreditch, E.—The Vestry require tenders for engines, electric generators, switchboards, pumps, steam and water mains, cast-iron work, motor transformers and accumulators. Specifications, etc, can be obtained on and after 23rd inst., of the consulting engineers, Messrs Kincaid Waller, and Manville, 29, Great George-street, Westminster S W, on payment of £3. 3s, which will be returned on the receipt of a bona fide tender. Tenders, endorsed "Tender for Contract No 4" to be sent in by 4 p.m. on April 14. Further particulars will be found in our advertisement columns.

Bedford.—The Electric Light Committee invite tenders for the supply and erection of the following plant: (Section A) one 240-b h p double-acting compound enclosed engine, (B) one 150-unit alternator, with stationary armature. Specifications, with terms and conditions of tender and contract, may be obtained at the offices of Mr. T. S Porter clerk to the Urban Sanitary Authority, Town Hall, Bedford, on payment of a fee of 5s. for each section. Tenders sealed and marked "Electric Lighting, Section A or B" must be delivered to the clerk by April 4.

Chesterton (Cambs).—The Urban District Council are open to receive tenders for the public lighting of the district for seven years The tenders shall be made in the three following modes—namely, (*a*) lighting the district from August 14 to May 15 (inclusive) in each year; (*b*) lighting the district throughout the whole year commencing May 15 next; (*c*) lighting the district for either of the above periods (1) with ordinary burners, (2) with incandescent burners, if the illuminant with which the tender be made be gas. All cleaning, lighting, and maintenance to be done by the contractors Tenders to be sent to Mr James Spearing, clerk, 15, Sydney-street, Cambridge, by March 31.

Egremont.—The Wallasey Urban District Council require tenders for the following requisites—viz.: (a) steam alternators, switchboard, and accessories; (b) high and low tension concentric cables; (c) transformers. Copies of the specifications may be obtained on application to the engineer, Mr. J H. Crowther, Gas and Water Works, Great Float, near Birkenhead. A charge of £2. 2s. will be made for copy of each specification, to be returned on receipt of a bona fide tender. Sealed tenders, on the form to be provided for the purpose, addressed to the chairman of the Gas and Water Committee, and endorsed "Tender for Steam Alternators, Switchboard, and Accessories," or any other contract, as the case may be, to be delivered at the office of Mr. W. Danger, clerk, Public Offices, Egremont, by 4 p.m. on April 6. Each contractor will be required to enter into a bond with approved sureties for the performance of contract.

Antrim.—The Commissioners for the Control of Lunatic Asylums will receive sealed tenders up to 10 a m. on May 1 for the supply and erection of an electrical installation at County Antrim Lunatic Asylum. The tender should be sent in a sealed envelope, endorsed outside "Tender for Electric Lighting, County Antrim Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and should be accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tenders, and copy of specification, which has been prepared by Mr. J H. Greenhill, M I E E, will be issued on application to the office of the Board of Control of Lunatic Asylums, Dublin, on deposit of £3, which will be returned to all persons who have sent in bona fide tenders. Plans can be seen at the office of the architect, Mr. John Lanyon, Northern Bank-chambers, Royal-avenue, Belfast.

Bucharest.—The Communal Council require tenders for lighting the suburban districts of the city by some system which shall not require to be conveyed underground by means of pipes or otherwise, and which shall, in the opinion of the Board, be considered the most advantageous of all the systems submitted, with a view to substituting same for the 3,265 oil lamps now used for lighting the suburban streets and squares. The contract shall be given in accordance with the specification relating thereto, which has been drawn up by order of the Board of Technical Works, and approved by the Communal Council at a meeting held on January 24 The specification may be inspected any day during business hours at the office of the Agence Havas, 96, Queen-street, Cheapside, London, E C. The contract to be given for a term of five years from April 1-13, on which date the present contract runs out. Sealed tenders will be received from the 14th to 26th inst. Applicants must, in their tenders, refer to the items provided in Article 6 of the specification. All persons desirous of tendering are requested to attend at the Mairie on the day and hour above mentioned and lodge security for 15,000fr., failing which they will not be allowed to tender. The tender to be governed by Articles 68-79 of the General State Accounts Act.

Bradford.—The Corporation invite tenders for the following plant and machinery—viz.: (1) batteries: (2) surface condensing plant; (3) cables; (4) travelling crane; (5) steam and exhaust pipes. Forms of tender and specifications may be obtained on application to the electricity office, Town Hall, Bradford, on paying a deposit of £1 for each specification, which will be returned on receipt of a bona fide tender. Tenders, to be endorsed "Tender, Electricity Works," and addressed to the chairman of the Gas and Electricity Committee, and delivered at the town clerk's office, Bradford, by 25th inst. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages. The Corporation also invite tenders for the erection of a building required for the new electricity station at the junction of Valley-road and Lionel-street in the borough. Plans and specifications may be seen and bills of quantities obtained, free of charge, on application to Mr. Thomas Barker, A.M.I.C.E., architect at his offices, 5, Bond-street, Bradford, on and after 25th inst. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages. Tenders, endorsed "Tender—Electricity Works," to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by April 8.

RESULTS OF TENDERS.

Dewsbury.—The Town Council have accepted the tender of Messrs. Chadwick and Son for the supplying and fixing of an electric fan for the Turkish bath department and the constructing of an upcast shaft at a total cost of £20. 10s.

Namur.—The lowest tender for the construction of a telephone service building at Namur (March 10) was that of Messrs. Dandumont, of Namur, at 86,949fr. The highest was from Messrs E. Heine, of Huy, at 102,500fr. The estimate was 83,605fr.

Tunbridge Wells.—The tender of Messrs. Johnson and Phillips to supply a Willans engine at the central electric station for the Town Council, at £750, has been accepted. The Town Council have also accepted the tender of Mr. J. Jarvis for the extension of the electric lighting station at £1,356.

Durban (South Africa).—The Corporation have accepted the tender of Messrs. Andrew Handyside and Co, of Derby, for 70 cast-iron junction-boxes 400 cast-iron service-boxes, 70 cast-iron manhole frames, etc., covers, and 100 spare porcelain blocks, and 100 blank flanges for the electric lighting of the town.

BUSINESS NOTES.

Dorset.—The electric lighting of the new asylum has cost £2,000.

Dundee.—The committee are introducing electric lighting into the Scottish Liberal Club.

Portsmouth.—A new electric shop has been commenced on the site of the old convict prison.

South Staffordshire Tramways Company.—The receipts for the past week show an increase of £55.

Newcastle.—The City Council have voted a sum of money to provide for the electric lighting of the town hall.

Aberdeen.—A deputation of the Harbour Board have visited Liverpool to inspect the system of electric lighting at the docks there.

Railway Accident Insurance.—£1,000 tickets are now issued at all stations for all classes by the Railway Passengers' Assurance Company, 64, Cornhill, London.

Gravesend.—At the Town Council meeting the surveyor reported that the telephone to the sanatorium was now completed and in satisfactory order.

Matlock.—Accommodation has been provided at the town hall for an exchange for the National Telephone Company. The trunk line has reached the town.

Southend.—The Town Council are going to light the western esplanade, and a committee are considering the question of adopting the electric light.

Bangor.—A lengthy and detailed reply to the statement of the committee on the electric light question has been sent to the Board of Trade by the opponents of the scheme.

Richmond.—Upon the recommendation of the Electric Lighting Committee, the Town Council have approved of the plan from the electric lighting company to extend their area.

Cardiff.—The borough surveyor has been instructed to report on the lighting of Canton Bridge and of various streets. The public lighting is now costing something like 3½d. in the £.

Portrush.—The County Antrim Grand Jury have approved a proposal that the Giants' Causeway electric tramway should change the present system of electric traction to the overhead system

Coventry.—Mr. R Hammond, consulting engineer to the Corporation, suggests the laying down of a new set of plant of 400 i.h p, 200-kilowatt capacity, at an estimated cost, with additional cables, of £8,900.

Aberystwith.—At the Town Council meeting the Public Lights Committee recommended the Council to pay the electric lighting company £803. 19s, being the cost of arc lamps and pillars. The recommendation was adopted.

Sandycroft.—At the annual parish meeting the question of electric light cropped up, and it was suggested that they might erect a generating station of their own, with an oil engine and dynamo, near the centre of the village.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending March 15 amounted to £1,095, as compared with £975 in the corresponding week of the previous year, being an increase of £120.

Lytham.—At the meeting of the Urban Council a letter was read from the engineer to the tramway company asking for permission to be allowed to run two cars together. It was resolved that the request be not acceded to.

Chester.—At the meeting of the Town Council it was decided that the present arrangement with the gas company for lighting the

Digitized by Google

city should continue for six months instead of 12, having regard to the installation of the electric light.

Bradford.—The Gas and Electricity Supply Committee of the Town Council have passed the plans for the erection of new electricity works for the Corporation in Valley-road, and steps were taken for at once obtaining tenders for the work.

Ballymena.—The Town Commissioners have decided that there should be a telephone wire connecting Ballymena and Belfast, and they have instructed the clerk to write to the National Telephone Company and postal authorities in regard to it.

Ulverston.—The Rural District Council have acceded to the application of the Windermere and District Electricity Supply Company for an extension of time to carry out their obligation in regard to the deposit to be made with the Board of Trade

Electric Light in Hyde Park.—Among items which appear in the Civil Service estimates this session for the first time is a charge for the electric lighting, not only of the bandstand in the park, but also of the footpath between the Marble Arch and Albert Gate.

Brighton.—The Lighting Committee of the Corporation have decided to recommend the erection of electric arc lamps in Preston road, between Springfield-road and Stanford-avenue, and in Stanford avenue, between Preston-road and Beaconsfield-villas.

Ringwood (Hants).—At the District Council meeting an application from the Telegraph Department at the Post Office for permission to erect a telegraph wire at the side of the highway from Burley Post Office to the railway at Whitton Bridge was granted.

Kensington (London).—At the meeting of the Vestry a letter was read by the clerk from the Notting Hill Electric Lighting Company forwarding copy of the directors' report and accounts of the company to December 31, 1895. The letter was referred to committee.

Warminster.—The Urban Council has considered the question of the lighting of the lamp over the fountain both with electric light and the incandescent burners, and has decided that as the light nights were coming on the matter remain in abeyance for six months.

Londonderry.—Mr. Christie, electrical engineer, has reported on the recent failure of B and D circuits. He states that the cable faults were not due to any latent defect, but the cables had evidently been damaged by picks when the ground was opened for service pipes.

Post Office Estimates.—The sum of money provided in this year's estimates of the revenue departments for the pay, rent, and office expenses of the local post offices in England and Wales is £3,650,336, being £2,679,690 for postal work, and £970,636 for the telegraph service.

Dewsbury.—A discussion took place at the meeting of the Town Council as to whether the arc lamps should be lighted or not on Sundays. The committee in their report did not entertain the suggestion, and the Council eventually upheld their view despite considerable opposition.

Leeds.—The exterior of the new town hall will be lighted by seven arc electric lamps. They are to be fixed to standards set in the footpath, and will extend along the building from Norfolk-street, along New Surrey-street, and as far as St. Paul's Church gates in Pinstone-street.

Ashbourn.—The promoters of the Derby and Ashbourn Tramways Bill have officially notified the abandonment of this Bill for the present session. The proposed tramways were intended to be worked upon the overhead trolley system. The total cost of the tramways was estimated at £31,172.

Ashton-under-Lyne.—The Town Council have consented to the application of the promoters of the proposed Oldham, Ashton under Lyne, Hyde, and district electric tramways for a provisional order authorising the incorporation of a company and the construction and maintenance of tramways.

The Isle of Man Tramways.—At an extraordinary general meeting of the shareholders of the Isle of Man Electric Tramway Company sanction to purchase the Snaefell Mountain Railway for £72,500 was unanimously confirmed, and it was decided that the capital of the company be increased to £175,000.

Leicester.—The electric lighting department accounts show a deficiency on the half-year, after providing for interest and sinking fund, of £185. 7s 2d., which is a considerable improvement on the previous half-year, and is considered very satisfactory seeing that it has only been established one year.

Bourg (France).—The River Ain having overflowed it banks, a dam at Oussiat, near the Joly Electric Works, was carried away. At Pourcin, a manufacturer was proceeding to his machinery-house in a boat, with his engineer and two electricians, when the craft was capsized, two of its occupants being drowned.

High-Voltage Fittings.—The Edison and Swan Company inform us that, in order to meet the present requirements for fittings of a high insulation for high-voltage currents, they are now ready to supply switches, cut-outs, and holders with patent enamel liners. Sample Tumler switches are on view at their offices.

Williamson and Joseph, Limited.—This Company has been registered by M. Moseley, 303, Strand, with a capital of £10,000 in £1 shares, of which 5,000 are 5 per cent. cumulative preference, in order to enter into an agreement with E. L. Joseph, and to carry on the business of electrical engineers and electricians in all its branches.

Radcliffe.—The surveyor has reported to the District Council that the possible users of electrical energy within 200 yards of the lines to be laid down in the compulsory area were as follow; lamps, 182; shops, 185; beerhouses, 17; public-houses, 7; dwelling-houses, 1,246; mills, workshops etc., 23; and churches, chapels, schools, etc., 15.

City and South London Railway.—The returns for the week ended March 15 were £949, compared with £912 for the corresponding period of last year, being an increase of £37. The total receipts for the half-year terminating as above were £10 786, compared with £10 823 in the same period of the preceding year, being a decrease of £37.

Godalming.—The Board of Trade have issued a provisional order (with a view to the same being included in a Confirmation Bill, about to be introduced into Parliament) authorising the Corporation to supply electrical energy for all public and private purposes as defined by the Electric Lighting Act, 1882 and 1888, within the whole of the borough.

Hove (Brighton).—The Fire Brigade have asked the Urban Council to take into consideration the question of establishing a system of electric fire alarms for the better protection of the town. The resolution has been referred to the surveyor and the chief constable to report on the practicability of carrying out the suggestion, and the cost of doing so.

Fleetwood.—The Urban Council have given their consent to the Blackpool and Fleetwood Tramroad Bill, and they have sanctioned an extension of the time for purchase of the tramway by the local authority from 21 to 30 years, but, on the other hand, the time for completing the construction of the works has been reduced from five years to three years.

Southampton.—The Works Committee recommend the Corporation to purchase the undertaking of the Southampton Electric Light and Power Company, Limited, for the sum of £21,000, and that application be made to the Local Government Board for a loan of £50,000 to complete the purchase and to carry out the necessary extensions of the undertaking.

Morecambe.—The District Council have appointed a sub-committee to look out for a site for electrical works for supplying electric light, suggest a scheme for supplying the light, and prepare the application to the Board of Trade and the Local Government Board, with power for the sub-committee or some of them to visit such electrical works as they may think advisable.

Birmingham.—The committee of the Medical Institute, in submitting their report for the year 1895, record the installation of the electric light in the library and reading-room. It has not been in use long enough to enable a full statement to be made as to its cost as compared with gas, although, so far as can be judged from a three months' trial, it seems likely to effect a distinct saving.

Douglas (Isle of Man).—A correspondence has been going on in the local Press as to the relative cost of the electric light and gas. Mr. E Berry champions the cause of electricity and quotes the "Town Councillors' Handbook to Electric Lighting" to prove his statement that for 6d. (the average charge for the unit) one can be supplied with current to light between 33 and 40 8 c.p. lamps for one hour.

New Company.—The Cottonwood Water Power and Electric Company, Limited, has just been formed, with a capital of £210,000, for the purpose of acquiring the waters, waterfalls, reservoir sites, and lands necessary for the operations of the Company of and in the Little Cottonwood Creek, situated near Salt Lake City, Utah, U.S.A., and of erecting a water-power plant for the supply of electrical current.

Walsall.—At the meeting of the Town Council the Electric Lighting Committee reported that the total number of consumers was 52, and that the income during February amounted to £120. 10s., less 2½ per cent. for prompt payment. The Ex-Mayor, in answer to a question, said the committee had decided to lay the mains on to the public baths, and would be glad to extend the mains to any part of the town from which there was guaranteed a remunerative return.

The Copper Market.—Stocks of copper in England and France, including shipments advised from Chili and Australia, are shown in Messrs. Henry R Merton and Co 's circular to have decreased by 2,406 tons between February 29 and March 15, but during the same period the quotation for G.M.B.'s has declined from £46. 10s. to £44 17s. 6d. The quotation is, however, about 12s. 6d. higher than it stood at a month ago, and very considerably above that ruling at this time last year.

Yarmouth.—The electric supply accounts for February show that the receipts exceeded working expenses by £80. 2s. 9d., but the charges for repayment of capital, interest, rates, and insurance amount now to £100 per month. Five more customers have been obtained for 350 lamps, making the total 150 customers for 6,997 lamps The surveyor has been directed to lay mains, etc., on the North Quay as soon as customers had been obtained in the district to the extent of £50 per annum.

New Electric Pump.—Messrs. Merryweather and Sons have just supplied for Lord Rothschild's mansion in Piccadilly a new treble-barrel pump of novel construction, driven by an electric motor, to work as a pressure augmentor on the fire-main system. The driving current is taken from the electric lighting system, and the motor drives the pump direct and works silently. This pump is also to be seen at work at the firm's Long-acre house, and is suitable for water-supply work, as well as for fire extinction.

Islington, N.—In our description of the Meldrum blowers at the electric light station the statement that "the furnaces can burn 40lb. of fuel per square foot of heating surface" should have read "per square foot of grate surface." At the Vestry meeting the clerk reported that he had received a copy from the Board of Trade of

Digitized by Google

new regulations with reference to electric lighting to ensure the safety of the public and ensure proper and sufficient electrical energy. The matter was referred to the Electric Lighting Committee.

Edinburgh.—A sub-committee of the Edinburgh Town Council has had under consideration the application of the National Telephone Company for permission to lay underground wires in the city. The meeting instructed the town clerk to ascertain precisely the position taken up previously by the Town Council on the telephone question, and also the obligations which Edinburgh was under to Glasgow in connection with the subject The Town Council have passed a resolution which finally commits them to the cable system for their tramways.

Chiswick.—At a special meeting of the District Council the clerk reported, in reference to the agreement with the Duke of Devonshire as to the electric lighting works and dust destructor, that the Law and Parliamentary Committee had inspected the document and was not satisfied as to the clause relating to nuisance. The Duke's agents, on the other hand, declined to waive the clause. He had offered them a general clause as to nuisance, but they would not accept it. The agreement was referred back to the Law and Parliamentary Committee.

Electric Lighting in India.—There are several schemes afloat for introducing electricity in Bengal. The project for lighting Darjeeling has, it is stated been accepted by the Commissioners. In Calcutta, besides the Seebpore College lighting scheme and that for the Alipore Jail and Belvedere, the main project for lighting a portion of the city is being taken up by several firms, including Messrs. Martin and Co., but the acceptance of a scheme or schemes for general lighting depends upon a complete procedure being laid down under the Act, steps for which are in progress.

Dover.—The Town Council have received the revised Board of Trade regulations to provide for the safety of the public in regard to electric light. The electric light company have written in reference to the lamps from the Market-square to the sea-front, pointing out that the column proposed was not applicable to arc lighting, and also that the light was better distributed on the higher columns, and they produced statistics from 14 other towns showing that the height of the columns was generally higher than in Dover. The matter has been referred to the Lighting Committee for report.

Taunton.—At the meeting of the Town Council the Electric Lighting Committee presented the statement of the accounts for the year ending December 31 last. The committee reported that the laying of the cables and other works in connection with the No. 3 sub station was progressing satisfactorily. Alderman Potter, in moving the adoption of the report, said it must be satisfactory to the Council to learn that during the last 12 months they had only drawn £350 from the rates, as against £1,100 during the previous 15 months. Councillor Sibley seconded, and the report was adopted.

Catalogues.—We have received the complete catalogue of the Electrical Company, Limited, of 122 Charing Cross-road, W C. The first half of this, dealing with dynamos and motors, was noticed by us some time ago. The second part deals with the "Luna" arc lamps, measuring instruments, switches and fittings, carbons, incandescent lamps, and electric bells The two parts are bound together in green cloth, and provided with a thumb index. We have also received from Messrs. Cutting Bros, of Parliament Works, Derby, their price-list of continuous-current dynamos and motors.

Dublin.—The Master of the Rolls has refused a motion for an injunction to restrain the Corporation from attaching their seal to a resolution, passed at their last meeting, giving the Southern District Tramway Company permission to extend their lines into the city from Haddington road to Carlisle Bridge The Southern District Tramway Company is mainly, if not entirely composed of the financiers who are working the Bristol tramways system The tramway lines in the city and running out to the suburbs are owned by the Dublin United Tramway Company, and a sharp rivalry is maintained between the two companies

Grimsby.—At a meeting of the Public Lighting Committee, the Chairman brought forward the question of the electric lighting of the borough. In 1894 they obtained from the Local Government Board a provisional order, but unless something was done in regard to the lighting it would terminate on July 3 of this year. There would be really no difficulty at all in getting the money. They would be very large consumers themselves, for it now cost the borough every year for gas £3,389 one-fourth of the last rate of £15,000. A good many residents in the town had already made use of the light. After some discussion, a sub-committee was formed to investigate the question.

Hampstead (London).—The Vestry have appointed Mr. Hudson, as the architect, to prepare plans and specification for the necessary additions to the electric lighting station and to superintend the carrying out the work. The resignation of W. Bathurst, assistant electrical engineer, was received and accepted. The following are the surveyor's estimates for the lighting account for the ensuing year: gas for public account, £6,300; electric lighting, Finchley-road, £1,014; removals and repairs, new lamps and services, £200; interest and principal (electric lighting loans), £3,008; working expenses (central station), £6 000; proportion of establishment expenses, £414—total, £16,936.

Manchester.—Three youths, named William Sidley, Percy Pattinson, and Thomas Ball, were charged at the police court last week with damaging telephones at Reddish, on March 1, by throwing stones at the insulators on telephone posts Defendants were each fined 5s., or seven days. In reply to a statement recently published, the general manager of the National Telephone Company writes to the *Manchester Guardian* to make it clear that subscribers to what Mr. Wm. Thomson called an "independent telephone system" would not have the right to speak over the Post Office trunk wires to any exchange in the United Kingdom on the same terms as subscribers to the National Telephone Company could.

Swansea.—The report of the directors of the Swansea Improvements and Tramways Company states that during the half-year under review negotiations had been actively carried on with the Corporation of Swansea for the purchase by them of the tramways, and for the lease of the undertaking to the company, in anticipation of the time fixed by the Acts of Parliament. This was done to enable the Corporation to relay the lines in a manner suitable for electric traction, and the negotiations included an agreement for the purchase of electrical power from the Corporation by the company, but the negotiations had been brought to a close by the Corporation, and they had withdrawn the Bill in Parliament which they were introducing for the purpose of obtaining the necessary power to carry out the agreement

Bristol.—The Electrical Committee still continue to receive substantial applications for current from private sources. There have been 506 such applications since the light was introduced, and of these 489 have already been complied with to the extent of 28,021 lamps. The total number of lamps applied for by the 506 applicants is 30,509, and the balance is being dealt with at the present moment. The Docks Committee want to light the Bristol Granary by electricity, and Messrs. Marden, Son, and Hall wish to introduce it into their Broad-street factory on an extensive scale. At their last meeting the committee had before them a request for the removal of the electric lamp column at the top of Union street, but as there are certain rearrangements contemplated in Wine street, it was decided not to deal with the request for the present.

Leamington.—At the meeting of the Town Council a letter was read from the Midland Electric Light and Power Company, stating that they believed an erroneous impression prevailed that they should be unable to take up the lighting of the town by means of arc lamps, or that their charges for such lighting would be in excess of those made to other towns. They ventured to inform the Council that they had no difficulty in arranging to supply public lighting of this nature with perfect satisfaction to themselves, and they believed they could, if invited so to do, offer a definite number of lamps and quote the Council a satisfactory price for such lighting. Arc lamps for public lighting had become very popular and had greatly benefited the towns where they had been adopted. The letter was referred to the Watch and Lighting Committee.

Direct Spanish Telegraph Company.—The report of the Direct Spanish Telegraph Company, Limited, for the year ending December 31, states that the accounts show a balance to the credit of revenue of £13 239. After providing for interest on and redemption of debentures, and adding £5,000 to the reserve fund, the balance of revenue amounts to £5,801, and the directors recommend the declaration of a dividend of 10 per cent. on the preference shares, and 4 per cent. free of income tax, on the ordinary shares, which will absorb £5,486; half of this amount was distributed in October as an interim dividend in respect of the June half-year. A balance of £315 will remain to be carried forward. The reserve fund will now amount to £28,498 The traffic receipts show an increase of £4,572, and the ordinary working expenses advanced £238. The cables and the land-lines in connection with them have continued in good working order.

Ealing.—At a meeting of the District Council the clerk read a communication from the Board of Trade, enclosing a copy of new regulations for ensuring the safety of the public, and a proper and efficient supply of electrical energy made by the Board under the powers of the Electric Lighting Acts, and the Ealing electric lighting order. The regulations were referred to the Electric Lighting Committee for consideration The committee reported that they had considered the question of wiring the churches upon the line of the electric mains, of which there appeared to be eight, Episcopalian and others. The committee considered the question of considerable importance, as the introduction of electric light into the churches would utilise the staff and the machinery when not used for other work, and they recommended that representatives of the churches be invited to meet the chairman and the clerk to discuss the matter. This was agreed to.

Lithanode Company.—We have received from the Lithanode Electric Storage Company, 3, Harvey's-buildings, Strand, W.C., a copy of their catalogue of their cells, hand lamps, and medical batteries. The Company in a circular to their customers state that, owing to increased business, it has been found necessary to enlarge their works and provide more adequate accommodation for offices and showrooms. Accordingly the Harvey's buildings premises have been secured, where in future all the business of the Company will be transacted and all communications should be addressed. The new premises include offices, showrooms laboratory, and stores of material required for temporary and decorative electric lighting. Arrangements have also been made for recharging and repairing portable batteries at that address, but returned packing-cases, raw materials, and heavy goods should be sent to the works, at 64, Millbank-street, Westminster, S.W.

Liverpool.—The Health Committee have again considered the request of the National Telephone Company that they may have permission to place the main trunk wires in the central portions of the city underground instead of overhead. A report was presented by the town clerk as to the conditions and terms under which the

Digitized by Google

concession might be granted. The chief road surveyor likewise submitted in detail the results of his inspection and enquiries in Manchester, where the system has been adopted. There the wires are carried along a deep trench made in the streets and roads, and certain charges are imposed upon the company for the privilege. The committee authorised the town clerk to submit what is really the draft of a proposed agreement to the Telephone Company. The negotiations are likely to occupy some time and the committee will make no recommendation to the Council until they are thoroughly convinced that a satisfactory arrangement can be entered into with the company.

London School Board.—The School Board for London has determined to make an alteration in the system under which the electric lighting is carried out at the head offices on the Victoria-embankment. Hitherto the eastern portion of the offices has been lighted by current supplied from the mains of the Metropolitan Electric Supply Company, and the remainder (considerably the greater portion) has been lighted by means of the Board's own dynamos. The cost of working the Board's engines, dynamos, etc., for the year ending December, 1895, was £806; and the cost of supplying the eastern portion of the offices from the company's mains during the first five months of the year was only £70 It has been decided to obtain the whole of the supply in future from the mains of the Metropolitan Electric Supply Company. It is estimated that under the new arrangement the six winter months will cost £318 and the six summer months about £70, making a total of £388. Under the old system the cost was over £900.

Newmarket.—At the meeting of the Urban Council the surveyor presented a report on the subject of electric light. He estimates that an installation capable of supplying 4,000 8-c.p. lamps connected can be worked at £600 per annum, after paying interest on capital and sinking fund. He does not think this installation would cost more than £10,000. The cost of production might be taken as under: total works cost, including rates and taxes, 4½ per cent. generating 72,000 units, at 4½ per cent., £1 350; interest on £10,000 loan, at 3 per cent., and repayments to extinguish in 30 years, £510—total, £1,860. Revenue, average units sold per 8 c p connected—say, 18–4,000 by 18 equals 72,000 per annum at 8d. per unit, £24,000, besides meter rents. By having their own electric lighting station they would economise in capital, outlay, and maintenance expenses, and would be able to supply private consumers at a moderate rate. Street-lighting was not dealt with in the report. The cost of lighting the High-street with electricity would be about £200 a year, against £150 for gas, but they would get 10 times as much light. It was decided to apply for a provisional order at once.

City of London.—The Commissioners of Sewers' engineer (Mr. D. J. Ross) has just issued his annual report on the works executed during the year. Referring to the subject of street-lighting, and after mentioning that the number of arc lamps in use in the City is 485, he says: "The important question of lighting the minor streets of the City by electric lamps, under the contract with the electric light company, has again been under consideration. The experiments with incandescent lamps, and with alternating-current arc lamps, in Basinghall-street and Aldermanbury not proving satisfactory, the Streets Committee on June 11 submitted a report from the electrical inspector, and recommended that further experiments with current arc lamps should be made, with the view to determine the description of lamp to be employed. This recommendation was agreed to, and referred back to the Streets Committee to carry out, and arrangements are now being made to light Watling-street, Bow-lane, Bread-street, Friday-street, and Old Change by continuous and alternate current lamps, partly on brackets fixed against the fronts of houses, and partly by lamps suspended across the centres of the streets."

The Hermite Electrical Sanitation Process.—The installation of this system at the military hospital at Netley has now been working since the beginning of the year, and a visit of inspection was made a few days ago by the War Office authorities, who expressed themselves thoroughly satisfied both with the effect on the main sewer and the effluent, and also with the remarkable improvement in the atmosphere of the various wards. The ward-masters are also unanimous in their approval. The French War and Naval Departments have officially approved the system, and are considering to which of their stations it shall be first applied. The Brazilian Government have given instructions for the Marine State Hospital at Rio to be fitted with the Hermite process on the same lines as the Victoria Hospital, Netley. As to the success of the demonstrations of the Hermite process at Rio last year, it may be of interest to state that in that part of the city where the working of the plant has been continued not a single case of yellow fever has occurred, though it is a most insanitary spot, and in previous years has suffered severely. Other parts of the city have suffered as usual from the periodical visitations of this scourge.

Camberwell (London)—The ratepayers have held a public meeting and passed a resolution condemning the action of the vestry in assenting to the proposals of a company to establish itself in the parish, and asking the Vestry to rescind its resolution on the matter. Mr. E. R. Phillips, as chairman of the Electric Lighting Committee of the Vestry, desired to explain the present position of affairs. In January, 1890, the Vestry gave away its right to supply electricity in the parish by allowing a company to secure a provisional order. That company still held that power, but had not taken action. Six or seven months ago another company came forward with a Bill, which had gone up to the Board of Trade, asking practically that they should be allowed to replace the company which at present had power to supply the parish. The Vestry could not oppose it, but they had insisted upon the insertion of a clause in the provisional order giving the Vestry power to buy up the company at the end of two years by paying such an amount of money as should be equal to a sum of £133 for every £100 properly expended on the undertaking. A resolution was also carried urging the Board of Trade to refuse its sanction to the provisional order applied for.

Windsor.—The Windsor and Eton Electric Installation Company having obtained the Corporation's provisional order, a demand for 4,000 lamps will be provided for. Mr. A. H. Preece, A.M I C E, the consulting engineer to the company, has adopted for this undertaking the three-wire low-pressure continuous-current system, which is similar to that used by the Westminster, Pall Mall, Notting Hill, Kensington, Knightsbridge, Charing Cross, and other companies. The generating plant is to comprise two high pressure steam-boilers. The whole of the arrangement of feed water pipes, steam-pipes, pumps, etc., is to be fixed in duplicate. There will be two combined engines and dynamos of sufficient capacity to light about 2,000 lamps; a properly designed switchboard will be erected; a large set of accumulators will also be installed. For the mains, Mr. Preece has adopted a conduit system for the feeders and a solid system for the distributing mains; and he proposes to provide in all the distributing mains and the feeders for a 50 per cent increase in the immediate demand. Mr. Preece's estimate of cost for plant, mains, buildings, etc., is £9,500. It is expected that the work of installation will shortly be commenced under the direction of Mr. A. E. Farrow, resident engineer.

Whitehaven.—The Town Council have decided to oppose the renewal of Dr. Hopkinson's patent in connection with the three-wire system, which patent expires in July next. The Lighting Committee reported that Dr. Hopkinson had tested the cables and found the contract had not been complied with by the contractors; that the insulation was enormously below the standard; that the conductors could not be brought up to it without laying, to a large extent, a fresh cable; and that, where necessary, a five-wire cable should be substituted for the present cable. Dr. Hopkinson also stated that he had a large experience of Messrs. Siemens in carrying out contracts, and his opinion was that, when he drew their attention to the defects, they would remedy them and honourably carry out their contract. It was then resolved that Dr. Hopkinson write Messrs. Siemens explaining the condition in which he found the cables, etc, and request them to remedy the defects, and put the whole into good and efficient working order, in accordance with the contract. Dr. Hopkinson further advised that additional accumulators should be laid down in some convenient position, so as to provide for the increasing consumption, and to meet prospective requirements for some years to come. He recommended the enlargement of the present storage battery, and the provision of a new and more powerful battery, which would be placed near to the point of heaviest load. He estimated the total cost of his recommendations at £1,616. 10s. The report was adopted.

Belfast.—The county surveyor (Mr. John H. Brett) presented a long report at the County Antrim Assizes on the proposed tramway schemes. He said the doubling of the lines as proposed would be very desirable and wholly unobjectionable were it not for the narrowness of one of the roads traversed (Falls road), and the inconvenience that may result. No specific provision was made for giving the county authorities power to intervene against a misuse of the powers which the company may acquire under these clauses. The Bill proposed that the limit of speed should be 12 miles an hour, but this ought to be varied so as to have a much less rapid rate for passing abutting roads or turning corners. It would be advisable to have a limit to the number of carriages or trucks in a train; to the distance between trains in motion; and to the time during which a train may be allowed to remain stationary; also, to require the company to use some very efficient and reliable form of automatic brake on all their carriages and trucks At a meeting of the Improvement Committee a letter was read from the National Telephone Company, Limited, in reference to the adoption of the underground system for their wires in the principal streets, and asking that some of the company's representatives should be received to discuss the matter with the Corporation. The question was held over for further consideration. The electrical engineer has reported on the effect the new regulations promulgated by the Board of Trade would have on the future operations of the department, and has received instructions as to the amending of the wiring by-laws now in force to conform to the new regulations.

Appointments Vacant.—The London School Board require for the training-ship "Shaftesbury," off Grays, Essex, a stoker mechanic having a practical knowledge of electric lighting apparatus and steam boilers; also capable of doing general repairs to pumps, cooking, and other apparatus. Commencing salary £50 a year (which may be increased by £2 10s. a year to £65 a year), with uniform, board, lodging, washing and medical attendance. Applications, in candidates' own handwriting, on forms to be obtained from the School Board Offices, accompanied by copies of not more than three testimonials, must state age and previous experience, be marked outside "Stoker Mechanic," and be received by the Clerk to the Managers, School Board Offices, Victoria-embankment, London, W.C., by 12 noon on 21st inst.—The Corporation of Ashton-under-Lyne invite applications for the appointment of a consulting electrical engineer, to advise the Corporation as to a contemplated scheme for the supply of electric lighting within the borough. Applications, accompanied by a statement of the works carried out by and as to the experience and qualifications of the applicants, must be forwarded by 23rd inst. to Mr. Charles Gartside town clerk, Ashton-under-Lyne.—The Corporation of Bolton invite applications for the appointment

Digitized by Google

of electrical engineer. Salary, £300 per annum. Particulars of duties may be obtained from Mr. R. G. Hinnell, town clerk, Town Hall, Bolton, to whom applications, endorsed "Electrical Engineer," stating age and experience, together with not more than four testimonials must be delivered by April 6.—At the meeting of the directors of the Aberdeen Infirmary it was resolved to advertise the vacancy in the combined office of assistant anæsthetist and assistant medical electrician.

Folkestone.—At the meeting of the Town Council the town clerk reported that the Board of Trade had sent down the provisional order, which was simply a copy of the printed one they had previously, with the exception of a few alterations. So far as he was concerned, the form of order was correct, and he asked for a resolution that it he approved and returned to the Board of Trade. Incidental to that matter, he had received a letter from a gentleman, writing from Parliament-street, Westminster, in which the writer said he understood the Corporation were applying for a provisional order, and would be obliged for information thereupon as to whether they proposed to transfer the order to some company. If so, he would be prepared to make a proposal on behalf of himself and the Metropole Hotel Company. The directors intended to light the hotel throughout by electricity, and unless a supply was assured by next autumn they would have to make their own arrangements. The writer was Mr W. B Hopkins. The town clerk read another letter from Mr. Charles C. Wampach, stating that if the Corporation proposed to transfer the provisional order he would pay the sum of £500 for it, and would be pleased to lay before them a scheme for lighting a part or the whole of the town. Councillor Penfold moved, and Councillor Vaughan seconded, that the order be approved, and this was carried. The Town Clerk said he had been asked by a gentleman as to whether any provision could be inserted in the order to permit of electricity being used for the purposes of locomotion. He had written to his agents, and the answer was that it was a question of law, but that they felt the Corporation could only use it for the purposes prescribed in the Act, and they doubted whether that would include electricity for any other purpose than lighting purposes. It was resolved to have a committee meeting of the whole Corporation to discuss matters connected with the electric light question.

PROVISIONAL PATENTS, 1896.

MARCH 9.

5253. Improvements in or connected with the electro-deposition of metals. Sherard Osborn Cowper Coles, 47, Lincoln's-inn-fields, London.

5274. Improved apparatus for the electro-deposition of metals. Alfred Sidney Smith, Thomas Alfred Smith, Roland John Smith, Sidney Smith, and Thomas Deakin, 11, Burlington chambers, New-street, Birmingham.

5295. Improvements in arc lamps. John Albert Seaverns, 24, Southampton buildings, Chancery-lane, London. (Complete specification.)

5298. Improvements in electric flashlight apparatus. Alfred Julius Boult, 323, High Holborn, London. (William Bruns, United States.) (Complete specification.)

MARCH 10.

3515. Improvements in the method of and means for electrically dispatching parcels from one station to another. Edward Henry Seddon 57, Barton-arcade, Manchester.

5320. An improved method of attaching the terminal wires to the zinc rods or cylinders of electric batteries. Isaac Hardy Parsons, 21, Narborough road, Leicester.

5345. Improvements in Gramme ring armatures. Roslyn Holiday and John Freeman, The Arcade, Barnsley.

5408. Improvements in telegraphic relays. Willoughby Statham Smith and William Puddicombe Granville, 24, Southampton-buildings, Chancery lane, London.

5412. Improvements in selecting and operating telephones. Theodore McKenna, 17, Basinghall-street, London. (Herbert Laws Webb, United States.) (Complete specification.)

MARCH 11.

5467. Improvements in appliances connected with electric tramcars and tramways. Edward Hawkesworth Hackett, Penny Bank-chambers, Halifax.

5479. Improvements in alternating-current electric motors for operating commuting devices for converting alternating into continuous currents and other purposes. Anthony Strong Fraser, 73 St Stephen's-road, Upton Park, London.

5480. An improved method of and means for locating leakages on systems of electric conductors. William Valentine Hunt, 73 St. Stephen's-road, Upton Park, London.

5491. Means of varying the speed of asynchronous alternate-current motors. Siemens Bros and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Siemens and Halske, Germany.)

5497. An electrically-controlled automatic stopcock. Selimo Romeo Bottone, The Limes, Stanley-road, Carshalton, Surrey.

5506. Improvements in electric accumulators. Paul Ferdinand Ribbe, 6, Lord-street, Liverpool. (Complete specification.)

5511. Improvements in arc lamps. William James Davy, 40, Chancery-lane, London.

MARCH 12.

5537. Automatic telegraph apparatus. Georges Hyvert, 8, rue des Princes, Brussels.

5584. Improvements relating to the use and treatment of carbon in electro-chemical or electrolytic processes, and to apparatus therefor. Alfred Coehn, 11, Southampton-buildings, Chancery-lane, London.

5616. Improved electrolytic processes and apparatus. Antoine Edouard Peyrusson, 53, Chancery-lane, London.

MARCH 13.

5673. Improvements in apparatus for refining metals by electrolysis. Alexander Stanley Elmore, 28, Southampton-buildings, Chancery-lane, London. (John Oliver Surtees Elmore, India.)

5703. Improvements in arc lamps. Alfred Julius Boult, 323, High Holborn London. (Wolf Boguslaw Jolles and Eugen Hugo Arthur Heinrich Ritter von Nollendorf, Austria.) (Complete specification.)

MARCH 14.

5752. Electric apparatus for use either as an electromotor or as an electricity meter. John Perry, the Finsbury Technical College, Leonard-street, London.

SPECIFICATIONS PUBLISHED.

1888.

6481. Electrically transmitting power. Lake. (Tesla.) (Second edition.)

1895

3341. Ventilating manholes, electric light boxes, etc. Nisbett.

7315. Electric storage batteries. Barber-Starkey.

7990. Telegraphy. Higgins.

8810. Indicating value of electric resistances Siemens Bros. and Co. (Siemens and Halske.)

14662. Electric signalling apparatus Karn and Payne.

24172. Galvanic batteries. Iwanowski.

1896.

207. Arc lamps Thompson. (Electric Arc Light Company.)

1427. Telephonic apparatus. Marcuse.

NOTES.

The South African Cables.—Last Friday the Telegraphs Department gave notice of considerable delay in forwarding messages to South Africa, the East Coast, the Seychelles, Mauritius, and Madagascar.

New Edition.—Messrs. Whittaker and Co. will shortly publish Vol. I. of a new edition of "Electric Lighting and Power Distribution," by Mr. W. Perren Maycock, M.I.E.E. The work will be completed in two volumes.

Liverpool Electric Railway.—At the conclusion of the visit of their Royal Highnesses the Duke and Duchess of York to the Earl and Countess of Derby at Knowsley, it has been arranged that the Duke and Duchess will go to Liverpool and take a journey on the Overhead Electric Railway.

Acetylene.—A petition has been introduced in the Massachusetts Legislature praying that the manufacture and sale of acetylene gas be prohibited on the ground that it is dangerous to life and property. It is also asked that the storing of the chemicals from which it is manufactured be forbidden. A committee of the State Legislature is wanted to investigate and report on the matter.

Carbide of Manganese.—Mr. Henri Moissan has prepared Messrs. Troost and Hautefeuille's manganese carbide in the electric furnace. It is a definite compound corresponding to the formula Mn_3C, and decomposes water with the production of methane and hydrogen. It has been long known that metallic manganese prepared in the ordinary way contains a proportion of carbon, but its properties are different, resembling those of cast iron.

Electric Traction.—According to the *Progresso*, two engineers (Messrs. Martino and Boubée) have worked out a plan for electric traction between Rome and Naples, using the waters of the Volturno as a source of energy, there being, it is stated, a fall capable of giving more than 21,000 h.p. As our excellent contemporary *L'Elettricità* remarks, we must wait for further details before pronouncing whether so large a project can be actually realised.

Spanish Transatlantic Cable.—With reference to the project of a Spanish cable from the Canaries to Cuba, which has been fully described in previous notes, it is now stated that Messrs. Siemens have made propositions to the Spanish Government which the latter have accepted in principle in reference to laying it. The nature of these propositions, of course, is unknown, but the Spanish cable appears a good deal nearer accomplishment than at first seemed probable.

Telegraphs to India.—The Bengal Chamber of Commerce has been urging that there should be cheaper telegraphic communication between England and India. It has been suggested that the example of Australasia and South Africa should be followed. In that case the Governments concerned took half the risk of the loss, the telegraph companies took the risk of the other half, and after a year or two's working the enlarged traffic did away with the loss entirely.

A Sultan's Toy.—The Sultan of Morocco has had built a miniature electric railway, which passes through the different parts of the palace, ending in his bedroom. The equipment includes a car, in which his highness can sit comfortably and smoke while he is making his trip through the palace, which he does several times a day. The cost of this luxury is said to have amounted to £20,000. It should be added that this information does not come direct from Tangiers but from America.

American Institute of Electrical Engineers.—On the occasion of the February meeting of the American Institute of Electrical Engineers held at New York on February 26, before proceeding to the regular business of the evening, a vote was taken on the question of incorporating the institute. The result was unanimously in favour of incorporation. The regular business of the evening was the discussion of Mr. Frank J. Sprague's paper on electric elevators, which was read at the January meeting.

Vienna Exhibition.—In reference to the proposed plan of organising an exhibition in Vienna during the year 1898 in connection with the fiftieth anniversary of the Emperor Francis Joseph's accession to the throne, it is stated that the Lower Austrian Industrial Society has expressed its willingness to finance the enterprise, and that it is proposed to hold the exhibition in the old exhibition building in the Prater and in the spacious grounds which surround it. The exhibition is to remain open from the beginning of May, 1898, until the middle of October in the same year.

Institution of Junior Engineers.—At the conversazione to be given on Saturday at the Westminster Palace Hotel there is to be an exhibition of models and scientific instruments. Mr. A. A. Campbell Swinton will exhibit the new photography, Mr. Robert Paul will show his theatrograph, Mr. Wimshurst has promised experiments with the machine that bears his name, the electrophone will be laid on to the principal theatres, and there will be a musical programme, in which the names occur of Mr. T. E. Gatehouse, Miss Lane, and others, as well as Mr. W. Day's band.

The Telephone Companies.—In the House of Commons last Friday Mr. Henniker Heaton asked the Secretary to the Treasury what percentage of the receipts of telephone companies was payable to the State, and what amount was actually received by the Post Office from the telephone companies during each of the past five financial years. Mr. Hanbury replied that the royalty was 10 per cent. The amount received during the past five financial year was as follows: 1890-91, £44,070; 1891-92, £50,403; 1892-93, £57,620; 1893-94, £65,445; and 1894-94, £72,996.

Japanese Pacific Cable.—According to reports received by way of Canada, the Hawaiian Government have refused the application of Mr. Audley Coote for exclusive landing rights on the Hawaiian Islands for the proposed Americo-Japanese cable. Mr. Coote assured the Hawaiian Government that capital had been secured in Japan with which to construct the line immediately. He asked to be delegated to represent Hawaii in concluding a contract with Japanese principals on the basis of a draft contract submitted. This proposal was also declined by the Hawaiian Government as being beyond their power.

Electric Hæmostat.—At the meeting of the Birmingham and Midland Counties branch of the British Medical Association Mr. Lawson Tait read a paper on the use of a newly-designed electric hæmostat in intra-abdominal surgery. The principle involved is the coagulation under pressure of the albuminous elements of the tissues at a temperature between 180deg. and 190deg. F., the temperature being exactly regulated by means of the known resistance of a given quantity of platinum wire enclosed in a box of non-conducting material, and under the influence of a current accurately controlled by a rheostat or one of Lord Kelvin's balances.

The British Association.—A meeting of the townspeople of Dover has been held in connection with the visit of the British Association to Dover, which is to take

Digitized by Google

place in 1899. The reason arrangements were being made so far in advance is that the French Association wishes to make sure of the movements of the British Association before arranging to hold their meeting at Boulogne at about the same time. The French Minister for Foreign Affairs has written to the British Association asking them to hold their meeting at some English coast town, and this has led to the selection of Dover, which has the necessary accommodation for the sectional meetings.

Japan Telegraphs.—According to the Japanese *Electrical Friend*, the survey and preparations for the new cable from Kagoshima, Japan, to Formosa have been completed. The distance is about 900 nautical miles, and the total estimated cost is about £400,000. The cable is to be laid in the course of the summer. The Government is asking for something like £100,000 to improve and increase the telegraph service. For the year ending May, 1894, the total number of messages in Japan was 8,359,139, an increase of 27 per cent. over that of the previous year, while the gross income increased 55 per cent. The Government further propose to change the single-wire telephone system of four towns to a double-wire system, and to open 36 new exchanges.

Telephones and Thunderstorms.—Some time ago enquiries were made by the German Telegraph Department with a view to ascertaining whether the danger from lightning was increased or diminished by the presence of the miles of overhead wires which make up the network of a telephonic system. According to *Das Wetter*, the result of the enquiry has been to show that the presence of the telephone wires tended sensibly to diminish the violence of thunderstorms and to lessen the risk from lightning. A comparison made between 340 towns having a telephone system and 560 not provided with any showed that the ratio of the risk of damage from lightning was as 1 to 4·6 in favour of the former, while the frequency of flashes during a thunderstorm is lowered in the proportion of 3 to 5.

Crossed Wires.—An account is given in *El Telegrafista Español* of an accident which took place in Bilbao on the 16th inst. A wire of the Interurban Telephone Company broke and fell across a cable belonging to an electric tramway, this bringing both on to the telegraph wires. Several of these were melted, and there was a great display of sparks at the telegraph office and a great deal of damage was done to apparatus there. People tried to collect and remove the broken wires and received shocks, but nothing more serious appears to have occurred. Our contemporary, however, states that the occurrence was not altogether unexpected on the part of the telegraph office, and it is contended that the companies should have been compelled to arrange their wires so that such an accident would have been impossible.

Proposed American Pacific Cable.—At a sitting of the United States Senate Committee on Foreign Relations, Mr. J. H. Scrymser has appeared in the interests of the company which proposes to lay a Pacific cable. A bonus of 160,000dol. a year for a period of 20 years is asked for from the United States Government, and in return the company will bind itself to for ever transmit all Government messages free of cost. The rate proposed for private Japanese messages is 1·25dol. (5s. 2½d.) a word, and for Hawaiian messages 35 cents (1s. 6d.) per word, the Press rates to be one-fourth of these. Mr. Scrymser stated that the only obstacle to the early and successful establishment of his cable was the so-called exclusive grant of the Hawaiian Government to Colonel Spaulding, which, he declared, was in the interests of an English cable company.

Rontgen Radiations.—We have already noted that the light emitted by most fluorescing substances contains a proportion of the Röntgen radiations, and that a similar effect has been observed with several substances which give no visible fluorescence. Mr. Henri Becquerel has been investigating the matter, and in a communication made to the Paris Académie des Sciences states that radiations of this character obtained from various uranium salts discharge the electroscope and have all the properties of the new rays. They also appear to be reflected somewhat feebly, though in a perfectly regular manner, from a concave mirror made of tin, and Mr. Becquerel states that he has obtained evidence of "total reflection" and refraction with them in glass. Another communication from Mr. Troost was to the effect that the artificial blende prepared by him in the form of hexagonal crystals when exposed to sunlight gave off the new radiations in sufficient quantity to enable it to be used instead of a Crookes tube in cases where a long exposure was allowable, and that very good negatives had been obtained in this way. It would be a curious result if it should come about in some way like this that the whole of the electrical apparatus now used for producing the Röntgen photographs should be ultimately dispensed with. So far as the experimenters are concerned, the main problem which seems to interest them at present is the attempt to see into people's heads As brain substance is transparent, and bone more or less opaque to the new rays, no very striking result appears possible in this direction.

Lord Kelvin.—In the autumn of the present year Lord Kelvin will complete the fiftieth year of his tenure of the Chair of Natural Philosophy in the University of Glasgow. There are two other instances of an equally long incumbency by a professor at Glasgow. The first occurred in 1761, when Robert Simson, well known for his work on Euclid and other ancient Greek geometers, completed his fiftieth year as professor of mathematics. The second is that of Dr. James Jeffray, who was appointed to the Chair of Anatomy in 1790, and held office for 57 years. The prospective jubilee, both on account of the rarity of such instances and of the eminence of the professor now concerned, naturally calls forth the lively interest and the hearty congratulations of the university and the city of Glasgow, but it has been thought fitting that the occasion should receive a wider recognition, and a joint committee, including representatives of the university and the municipality, are taking measures to secure the participation of universities and scientific and learned societies both in the United Kingdom and abroad, many of which have already testified their appreciation of Lord Kelvin's distinction by conferring upon him honorary degrees or designations, or by enrolling his name among their members. These bodies are now invited to send representatives to a celebration to be held in Glasgow on June 15 and 16 next, on the former of which days a conversazione will be held in the university, and on the latter a banquet in the City Chambers. There is also to be on the same occasion an exhibition of mechanical, electrical, and scientific apparatus illustrating Lord Kelvin's inventive genius.

Telephone Business.—The *Elektrotechnische Zeitschrift*, in its issue of March 19, devotes its "Review" to the progress of the telephone system in various European countries. A good deal of space is given to England in view of the taking over of the trunk lines by the Post Office, and our contemporary incidentally remarks on the extremely high charges made in England as compared with Germany, and recommends the Post Office to reduce these if it desires to attract much business. At any rate it might begin with a cheaper tariff for a night service.

Digitized by Google

The urgent necessity of a continuous night and day service is then enforced for all offices with more than 200 or 300 subscribers. From a detailed list of European countries which follows, it appears that there is a continuous service in all the large towns on the Continent with the exception of Rotterdam and Stuttgart. For smaller towns business hours appear to vary considerably, the smaller states giving as a rule the greater facilities. Thus, Switzerland gives a continuous service for all offices with more than 200 subscribers, and Belgium begins as early as five and does not close till eleven. Portugal also appears to give a continuous service. A striking exception, however, is Wurtemburg, where the office hours are from 7 a.m. or 8 a.m. to 6 p.m., though in the capital, Stuttgart, they keep open four hours longer. No information has been obtained as to Hungary, except that there is a continuous service in Budapest, and our contemporary also professes no knowledge of the hours of business in Spain, Russia, Finland, and the Balkan States. Lastly, it is pointed out that the desirability of an all-night service is not merely a question of giving greater facilities for mutual intercourse between subscribers, but involves the increase of their personal security and welfare, since it places them in constant communication with the police, the fire brigade, and the doctor. A constant service at the larger offices is therefore not merely desirable, but imperative.

Tramways.—A quantity of statistics relating to the progress of electric traction in European tramway work are given in *L'Industrie Electrique* of March 10. These are mostly embodied in 10 pages of tables, which are brought up to January 1 last. There are also two additional pages relating to lines either in construction or projected. Owing to the date to which the returns are made up, the latter class does not represent the actual state of things at present in Great Britain, and doubtless it is much the same with several other countries, progress in the direction of the conversion of horse into electric lines having been very rapid. This, however, obviously does not apply to the statistics representing last year's working. During 1895 it appears that the number of electric tramways in Europe increased from 70 to 111, and their total length from 504 miles to 596. The aggregate power of the generating stations has risen from 18,150 kilowatts to 25,095 kilowatts, and the number of motor tramcars from 1,236 to 1,747. So far as track mileage is concerned, Germany heads the list easily with 251 miles of line. Next come France and the United Kingdom close together with 81 miles and 76 miles respectively. Austria stands by herself with about 45 miles, and then come Switzerland, Italy, and Spain in the order named. The rest are of small account, but with the exception of Bulgaria, Denmark, and Greece all the European nations have at least short lengths. Turkey is left out of the list; possibly our contemporary considers that nation only semi-European. It may be said that practically if the English lines are omitted the whole of the European working is on the overhead system. At least, there are only two conduit lines, one in Germany and one in Austria-Hungary. Four lines are worked with accumulators in France, one in Holland, and two in Austria-Hungary. There is also one central-rail line in France, otherwise the trolley reigns supreme. Our contemporary anticipates that before the time comes for publishing next year's list the Heilmann locomotives will be running on the Chemin de fer de l'Ouest, and considers it probable that several lines of tramways will adopt a system of overhead wires up to the town and finish their journey with accumulators, using the same cars and motors. So far as lines in course of construction are concerned, a large amount of work appears to be in progress in Germany and France. With regard to the projected lines, it is hardly worth while reproducing matter which is already out of date.

The Jacques Cell.—Endeavours are constantly being made to devise some method by which the energy obtained from the oxidation of carbon can be converted directly into current without the intermediation of the steam-engine and dynamo. The most recent attempt at the solution of this problem is embodied in an American patent issued to Dr. W. W. Jacques, of Newton, Massachusetts. Dr. Jacques's method is to immerse a cylinder of carbon in molten sodium hydrate and to force a current or blast of air into the molten hydrate in such manner that it becomes impregnated with oxygen in excess over that which sodium hydrate normally contains. A circuit being completed from the sodium hydrate by means of a collecting electrode not chemically acted upon by the molten hydrate and an extraneous conductor to the carbon, an electric current is stated to flow continuously through the collecting electrode and the exterior conductor to the carbon, the strength of the current depending primarily upon the rapidity with which the air is blown into the sodium hydrate. An arrangement for carrying out the process is figured in the New York *Electrical Engineer*. Beginning from the inside, first comes the carbon immersed in the caustic soda solution. A pump forces air into a rose which distributes it evenly into the caustic soda. The solution is contained in a Norway iron pot, which forms the positive terminal, the negative terminal being clamped to the carbon, which is supported in the pot by an insulating cover. The caustic soda solution is admitted and removed by pipes. The whole is surrounded by a furnace which maintains the active cell at a temperature of 400deg. C. to 500deg. C. It is stated that in this process the carbon is gradually converted into carbonic acid, which mostly bubbles up through the hydrate and escapes. The nitrogen with which the oxygen of the air is diluted, having no chemical affinity for any other substance present, simply bubbles through and escapes similarly. Although the greater part of the carbonic acid escapes, it is found that a portion combines with the caustic soda, and this, together with the ash from the carbon, slowly contaminates the caustic soda, and in the course of time lessens its efficiency. The efficiency may be maintained by drawing off from time to time a portion of the contaminated electrolyte and admitting a fresh portion. The contamination may be reduced by adding a small percentage of oxide of magnesium. The current obtainable by this type of generator is said to be very large, but the voltage is low. No definite data as to this or to the efficiency of the cell have up to the present been forthcoming.

Motorcars.—The Honourable T. R. B. Elliot, of Clifton Park, Kelso, has been riding about the border counties of Scotland in a motorcar, no man hindering him. Unfortunately he was imprudent enough to venture into Berwick, whereupon the authorities of that borough promptly asserted themselves and summoned him. The local bench inflicted the moderate fine of 6d. and the immoderate costs of 19s. 7d. The odd penny seems peculiar. A law is a law with the Berwick bench, though there are several forgotten statutes still in force that might startle them to hear of. The new Bill on the subject was introduced into the House of Lords on Monday by Lord Harris. He said the Bill proposed to exempt horseless carriages from the statutory provisions now in force, and, at the same time, impose restrictions with respect to weight and speed. It also reserved certain powers to the Local Government Board and to local authorities. The Bill was read a first time, and there seems little doubt of it passing through. What precise form it will finally take is more uncertain, as

Digitized by Google

the traction-engine owners may very probably consider it a suitable occasion for pressing the grievances under which they at present labour. In this connection Mr. James Gray, the secretary of the Electric Construction Company, Limited, has written to the *Times*, calling public attention to the injury our manufacturing industry, as well as the farming industry, is suffering from the legal obstructions to the development of cheap transport by electric traction and horseless vehicles. At present traction on highways by mechanical means is practically prohibited by the Locomotive Acts. If engineers had had free scope for their inventive faculties, traction engines would have been so greatly improved that the same volume of traffic could be carried on highways by mechanical means, but with far less wear and tear than is now done by horses. Railway construction was first developed in this country, and the early experience acquired by our contractors and engineers gave us for many years a monopoly in constructing railways and railway plant all over the world. We are now entering on a new era in locomotion, but our engineers are prevented by legal obstructions from acquiring experience in the new development, and foreign manufacturers who have had facilities for gaining experience are rapidly securing a monopoly of the new business. While Germany and America reckon their electric tramways by thousands of miles, we can only count by tens, and France has hundreds of horseless vehicles against our units. As a natural consequence American engineering companies, by the help of American capital, are providing South Africa with electric tramways; and—will it be believed ?—also England and Ireland. We hear complaints of our want of enterprise in prosecuting foreign business; but in this case at least the blame does not lie with our manufacturers.

Telephones in the Country.—At a meeting of the Fife Farmers' Club last week a paper was read by Mr. Longmuir on the subject of the extension of the telephone service to the rural districts. It was only recently, he remarked, that Government had commenced to show any great interest in telephones. Hitherto it might be said that they had been worked mainly by public companies, but, like the telegraphs, the time could not be far distant when the Government would and must secure the monopoly. Nothing could prevent the nationalisation of the entire system sooner or later, and nothing would hasten that desirable end so much as the cry of the rural districts for it. Referring to the majority report of the Royal Commission, Mr. Longmuir asked his hearers to consider the Government proposal "of promoting the co-operation of occupiers of land with the view of raising the standard of their products, and getting rid of middlemen between the producer and consumer." Now it was quite clear if the farmer was to dispense with the middleman, he must have some means for getting into direct communication with the consumer. As things existed how was he to do so ? On the other hand, were the farmer in telephonic communication with towns and cities he would have an extended field of operation, and would have at his hand at any hour of the day as many buyers and sellers as he chose to establish relations with. The farmer would, by the aid of the telephone, have the entire week in which to make his bargains without the necessity of leaving his farm or waiting replies to letters and telegrams, or confining his trade to one market day or one centre. If they would give the rural housewife a chance of talking by telephone, he thought they might rest satisfied that she would not fail to find markets for her home products at wider ranges than at present. The Minister of Agriculture went abroad to see how light railways were worked, and came back favourably impressed. It was a pity he had not also looked at the working of telephones, and seen how necessary the one was to the other. This country was far behind others as regarded telephones. In Jutland every town and village not only possessed a telephonic exchange, but was connected by trunk lines, and the cost of the service was yearly from £2. 10s. to £3. 10s., the maximum being £4. 3s. 4d. In Norway the system was being successfully and economically worked by municipal and private lines. If Government had money to spare, and intended applying it to relieve the rural districts, let them spend it on some reproductive works, such as telephones. It will be remembered that the whole of this subject was gone into very fully at the last meeting of the British Association, and from Mr. Longmuir's vigorous advocacy, and the way it was received, it may be seen that the idea that there is an extended scope for the telephone in the country is spreading. Of course, it would not be a panacea for agricultural distress, but since what is done in Denmark and Sweden could be done in England, there is no reason for confining every improvement to the towns and leaving out the country altogether.

Electrical v. Steam Railways.—In view of the fact that several important schemes for electric railways are now before the public in one form or another, the *Financial Times* has been discussing from a financial point of view the question of the comparative merits of electricity and steam as a means of locomotion. The City and South London Railway has been in operation for over five years, and though its financial results have not up to the present been very satisfactory, that is due to its being practically the pioneer of this form of locomotion, and the experience it has had to pay for will prove of great value to its successors in this form of enterprise. Besides, it has shown steady improvement in its dividends, these having risen from nil in 1891 to $1\frac{3}{16}$ in 1895. The Liverpool Overhead Railway, though only opened in March, 1893, managed to pay a dividend of $2\frac{7}{8}$ per cent. for the year 1895 on its ordinary capital. This company is, however, in a specially favourable position on account of its low cost of construction. The higher cost of working by electricity has up to the present been a stumbling-block to its more extended use, but this is being gradually reduced. The amount of this higher relative cost of electricity as compared with steam may be seen from a comparison of the percentage ratio of working expenses to gross receipts in 1895 of the electric and the metropolitan lines. This stands as follows: Liverpool Overhead Railway, 63·0; City and South London, 60·6; Metropolitan, 43·2; Metropolitan District, 46·9. Where electricity as a hauling power is principally at a disadvantage seems to be its small earning power per train mile. The electric trains so far produced are small, and have not nearly so large a carrying capacity as the trains now running on the Metropolitan and District Railways. Therefore, it is necessary for the electric trains to run a much larger number of miles than would be necessary for the trains hauled by steam power to earn the same amount. From this it follows that, though the working cost per train mile on the electric railways is less than half the rate of the other two companies, the gross earnings are also very much lower. The average number of passengers carried per train mile, exclusive of season-ticket holders, in the case of each company was as follows: Liverpool Overhead, 11; City and South London, 14; Metropolitan, 44; Metropolitan District, 26. As regards initial cost, the City and South London has great advantages over the old underground companies, and the same feature applies to the new schemes for electric railways which have taken shape during the last few years. Per mile of its line, the City and South London cost on the

Digitized by Google

average less than £300,000, including equipment, compared with about half a million per mile in the case of the District Company. All this is doubtless true enough, but it is a little unfair of our contemporary to compare two lines built with the intention of supplying a service that should be something intermediate between a railway and a tramway service with two of the heaviest class of railways. Some people consider that the Metropolitan District has not been a brilliant financial success.

Civil Engineers.—The question of the standard with which the results of steam-engine trials should be compared has occupied considerable attention in several papers on steam-engine economy which had, during the past 14 years, been read and discussed at the Institution of Civil Engineers, and the subject was again taken up in a paper on "The Thermal Efficiency of Steam-Engines," read last Tuesday by Captain H. Riall Sankey, R.E. (retired), M.I.C.E. The view adopted was that in order to obtain full information of the thermal performance of an engine, two efficiencies had to be stated—namely, the absolute thermal efficiency and the "standard" thermal efficiency, the latter denoting the comparison of the actual engine with an ideal steam-engine working within the same temperature limits. In other words, the "standard" thermal efficiency was the absolute thermal efficiency of the actual engine divided by the absolute thermal efficiency of the ideal steam-engine chosen as the standard. It was the choice of this standard which had caused so much discussion. The true object of such a standard was to provide ready indication as to how far the particular engine under consideration fell short of what was physically possible within the limits of temperature by which the engine was bound, having regard also to the varying temperature at which the heat was supplied to the feed water, and it was shown that this requirement was met by the Clausius "perfect" steam-engine, slightly modified, however, as regards the point to which the expansion was carried. To assist in a decision as to the standard to be adopted, other ideal engines which had been proposed or used as standards were considered; for instance, the Carnot cycle, the engine whose expansion line was the saturated steam-line, and the engine the expansion line of which followed the law $p\ v =$ constant; and in each case it was pointed in what respects the requirements of the standard were not fulfilled. This comparison was also made by means of the $\theta\ \phi$ chart. The object of limiting the expansion, as suggested above by carrying it down to within 0·15 atmosphere of the actual back pressure, was to obtain a compromise between the two following conditions: if the expansion were carried to the back pressure, the standard would lead to the use of engines too large for their work; if, however, the expansion in the standard were only carried to a pressure equal to the back pressure plus the mean pressure (referred to the low pressure) corresponding with the friction of the actual engine, a premium was, so to speak, awarded to a stiff engine, and the standard would be made to vary with the stiffness of the actual engine. In many cases a comparison of the actual engine with what the author proposed to call the "type" standard was useful. The type standard was an ideal engine which took into account the clearance, compression, back pressure, etc., necessary with the particular type of engine under consideration. For instance, the ideal engine with an expansion line following the saturation line was the type standard for a jacketed engine. The difference in the amount of heat utilised by the standard and the type standard showed the unavoidable loss normal to the particular type of engine, whereas the difference in the heat utilised by the type standard and the actual engine gave the more or less avoidable loss.

Electric Tramways.—In the course of a lecture delivered at University College, Nottingham, on the subject of electric tramways, Mr. G. E. Coke, A.M.I.C.E., remarked that though the results of experiments with electric tramways in the United States had been so successful that continual additions were being made, in this country very little progress had been attained. The installations which were now in operation in the United Kingdom were small, and must be regarded as largely tentative and experimental. Mr. Coke thought that for many reasons the American appellation "street railway" was greatly preferable to the indefinite English term, "tramway." It was due to the energy and far-sighted policy of the Americans that their street railways were now the best in the world. Referring to American practice, it was remarked that it was not unusual for a street railway to lease its supply of power, either from another railway or from lighting and power distribution companies, on the basis of a given rate per car mile. Three-halfpence per car mile was about the rate charged for this service, and a company running 18 hours per day and making 125 miles per car per day would pay the supply company from 8s. to 16s. per car per day. In Chicago, New York, and San Francisco the cable system was at its best. In smaller towns, where the traffic was not so great, where curves and branches were of constant occurrence, where suburban routes were in question, or where the cost of roadbed and power plant must be kept within reasonable bounds, the electric system found a field that the cable system could never satisfactorily fill. In the great centres of population cable and electricity worked harmoniously together as component parts of the same system, each fulfilling that portion of the service to which it was best adapted. The enormous carrying power of an electric road when called upon to meet the demands of heavy service was an important feature of the system. With regard to Europe, the narrow streets of Continental towns had proved no barrier to electric roads. A noticeable instance of this was the Essen line, where the electric line traversed streets only 13ft. wide between house fronts. Some conversation followed principally in reference to the local circumstances of Nottingham. In answer to a question on the subject of gradients, Mr. R. J. Wharton, who represented the British Thomson-Houston Company, said that, so far as electrical tramways were concerned, he did not think they had yet reached the limit of gradients. The lecturer had shown a view of a gradient in San Francisco which was 1 in 7½, but he believed some eminent engineers maintained that that was not the limit. He believed that there were few places in England where they would meet such a steep gradient as 1 in 7½. As to the question of speed, they could run at any speed desired, but the Board of Trade and the local authorities did not like a high speed. With regard to the cost he might quote the instance of Bristol, where about four miles of double trams had been equipped for just about £50,000 on the overhead system. If, however, they went to the conduit, the system would cost much more. Sir John Turney, who presided, in moving a vote of thanks to the lecturer, said that he had seen no gradient or curve that a driver would hesitate or stop at. In Brooklyn drivers seemed to take no notice of curves, gradients, or roads, and some of the latter were like ploughed fields. He thought that they in England knew quite sufficient about electricity, and it was a pity that they had been so slow in applying it. The time had come when something should be done in Nottingham and other English towns.

LECTURE XXVI.

(Specially Contributed.)

Resistance Coils.—We have seen that the unit of resistance called the *ohm* is that of 106·3 centimetres of mercury whose sectional area is constant and whose mass is 14·4521 grammes at 0deg. C. or 32deg. F. For practical purposes mercury standards are useless; so secondary standards are constructed of German silver, or platinum-silver, or other suitable conductor are made. These are called resistance coils, and can be obtained in any desired multiples or sub-multiples of the ohm. A good deal of skill has been brought to bear upon the making of resistances, but there are certain broad lines which all makers follow. Fig. 1 shows

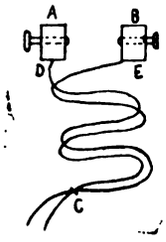

FIG. 1.

one resistance coil. Its resistance has to be carefully measured against standard resistances; it must be constructed of material that does not change its resistance much with change of temperature; it must be insulated against accidental contact with other conductors, guarded against moisture, and doubled back upon itself in winding, so that the field of one half neutralises the field of the other half, otherwise the field of the resistance might affect the instrument used in measuring. The workman takes two equal lengths of the wire—say German silver—to be used (by practice he knows about the right length), places the ends, say, D E, quite level, and solders together the other ends at C. He then has a resistance, D C E, which is accurately measured. If too great a resistance is found, the circuit is shortened by soldering up a little at the end, C, till exactitude is obtained. The wire is, of course, insulated. The free ends, D E, are connected to big conductors, A B, which form binding screws or contact-pieces, and have no appreciable resistance. The double wire is usually wound round a cylinder of wood, paraffin paper, ebonite, or other suitable material, and put into a containing box, which again is often filled with paraffin. A modification of this plan is shown (Fig. 2)—

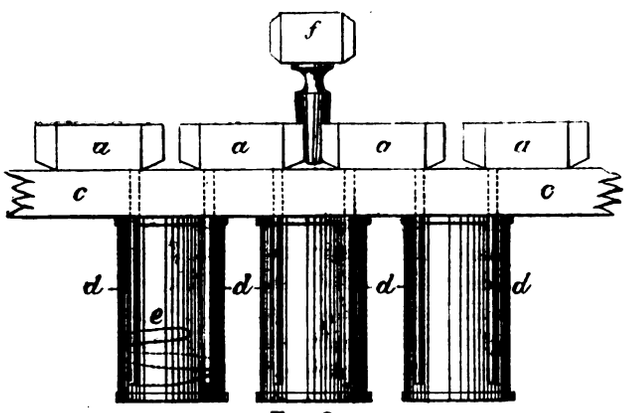

FIG. 2.

a a a a are thick blocks of brass or suitable conducting metal; *f* is a plug, the lower part of metal conical in shape to fit the conical holes bored in the blocks, *a a a a*, the upper part, *f*, is of ebonite or some non-conducting material; *c c* is an insulating cover. Below the cover are shown three boxes of ebonite or other insulating material. Each box contains two thick conducting rods, *d d d d*, going through holes in the cover, *c*, one rod being connected to one end of a block, *a*, the other rod similarly connected to the end of the next block, *a*. The end of the rods in any one box are connected by a wire, *e*, whose resistance has been carefully measured by comparison with standards. This wire is doubled on itself to prevent self-induction. The thick rods, *d d d d*, and the blocks, *a a a a*, should be massive enough to have no observable resistance. If, now, the boxes contain resistance respectively of 1, 2, 3 ohms, and so on, we can substitute these known for unknown resistances. In many cases the insulating boxes are not used, but a number of resistances are put into one box and separated by pouring in paraffin. When the plug, *f*, is out from two adjacent blocks the two resistances are in series, and by having a sufficient number of graduated resistances, they can be arranged so as to give any total resistance up to the limits of the apparatus. Fig. 3 shows another modification

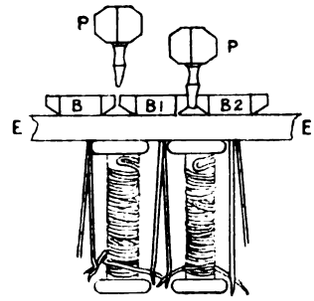

FIG. 3.

in the way of making the series of coils. B, B_1, B_2 are blocks of brass upon the ebonite slab, E E. One end of first coil is connected to B, and the other end to the one end of the next coil and block B_1, and so on. P P are contact plugs with ebonite tops, as before.

Resistance Boxes.—The large number of ways in which resistances are grouped in boxes makes it impossible to do more than illustrate one or two of them, but in

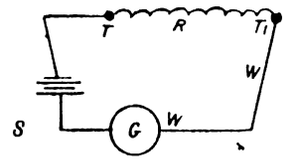

FIG. 4.

order to understand how resistance boxes may be used I will point out one or two cases of interest. Suppose, then, I have to find the value of an unknown resistance, the two ends of which can be connected to the two terminals for that purpose in a circuit, as Fig. 4. Here S may, as usual, indicate our source of electricity which of course, will be selected for the purpose in hand, the lines in the diagram signifying simply source. T and T_1 are two binding screws, between which the unknown resistance, R, may be connected. The circuit is completed through a galvano meter, as shown, and when it is completed the galvanometer will show a certain deflection. Note that deflection.

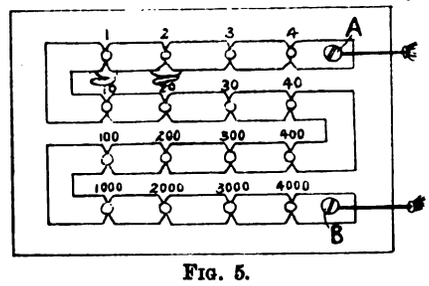

FIG. 5.

Now, if instead of the unknown resistance, R, I connect a box of known resistances between T and T_1, and unplug resistances till the deflection on the galvanometer is the same as it was with R in the circuit, then the sum of the resistances unplugged in the box will equal the resistance of R. In this case I merely substitute known resistances for the unknown, and when the deflection in the one case is the same as the deflection in the other, then I know the substituted resistance is the exact equivalent of the till then unknown. This method of

Digitized by Google

determining resistances is called the substitution method. It has the disadvantage that it is not always possible to get an exact substitution. We may not have sufficient known resistances to be equal to the unknown, or our known resistances may not be small enough or divided into sufficiently small sub-multiples to get an exact balance. Then, of course, we have to employ other methods. However, a box of resistances for the substitution method may be arranged as in Fig. 5, which will permit of the use of resistances in complete ohms from one ohm to 11,110 ohms. All the combinations can be made by means of one box containing 16 coils, each of the resistance shown by the number annexed to it. Connection with the circuit is made by means of the screws, A and B. Another arrangement is shown in Fig. 6. Here one contact is made through

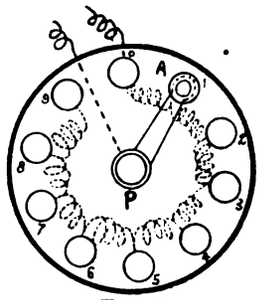

Fig. 6.

the central pivot, P, and another through the terminal, O. The resistances in the circuit vary according to the position of A. As shown, the resistance 01 only is in circuit. If A was moved on to contact 5 then all the resistances between 0 and 5 would be brought into the circuit.

Gilbert or Wheatstone's Bridge.—I have indicated that the substitution method can only be used under certain conditions. If these conditions do not hold other methods must be followed, and one of very general service for which many forms of resistance boxes are made is the Wheatstone bridge method. Suppose Fig. 7 to represent a complete circuit with source, S, and branch conductors, A C B, A D B between A and B. Let A C B = A D B in all respects. If, then, I take a point, C, in A C B, and a point, D, in A D B, so that A C = A D, and join C D through a galvanometer, G, there ought to be no deflection on the galvanometer, because the pressure at C should = pressure at D. No matter the pressure at A, if A C = A D in all respects, the fall of pressure along A C should be exactly similar to the fall of pressure along A D. Whatever current goes through A C, then, will go through C B, and, similarly, whatever current goes through A D will go through D B, and no current will go from C to D, because the pressure at the two points is equal. That is the simplest case. Further, only suppose that the resistance A C B

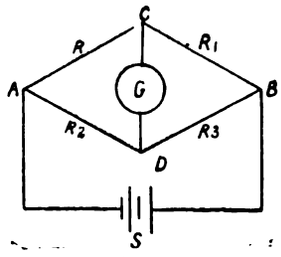

Fig. 7.

= resistance A D B, and that C and D are two points respectively in A C B and A D B, such that when joined through a galvanometer no current flows through the galvanometer; then C and D must have the same pressure, and C must divide the whole resistance A C B in the same proportion as D divides the whole resistance A D B. Calling the resistance A C = R, C B = R_1, A D = R_2, and D B = R_3, we may write

$$R : R_1 :: R_2 : R_3,$$

which reads: the resistance R bears the same ratio or relation to the resistance R_1 as the resistance R_2 bears to R_3.

A little knowledge of arithmetic and algebra tells you that $R : R_1 :: R_2 : R_3$

may be written $$\frac{R}{R_1} = \frac{R_2}{R_3},$$

whence $$R_3 = \frac{R_1 R_2}{R}.$$

If now R_3 is an unknown resistance, it can be determined if we know R_1, R_2, and R.

Fig. 8 shows a form of resistance box so arranged that the unknown resistance forms one arm of the bridge, such

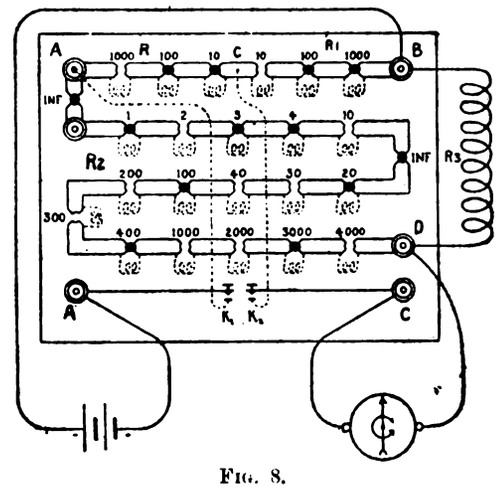

Fig. 8.

as R_3 in Fig. 7, and the other three arms are formed by the arrangement. I can make this clearer by means of the diagram taken from Niblett and Ewen's "Instruments." The source is connected through K_1 to the point A and to B. The resistance R is A C and R_1 is C B. The three rows of resistancess 1 to 4,000 represent A D, and the unknown resistance between D B represents R_3 in Diagram 7. The galvanometer, G, is connected through K_2 between D C. This arrangement is known as the Post Office pattern.

Suppose, now, in A C (R) we employ 1,000.
" " C B (R_1) " 10.
" " A D (R_2) " 2 + 10 + 30 + 40 + 200 + 300 + 1,000 + 2,000 + 4,000 = 7,582,

then, as $R_3 = \frac{R_1 R_2}{R}$

$$= \frac{10 \times 7,582}{1,000} = 75{\cdot}82.$$

Hence you will see that by this bridge arrangement we can easily measure the parts of an ohm although all our coils are multiples of an ohm.

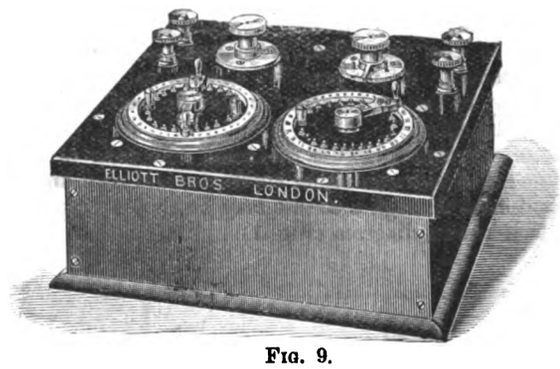

Fig. 9.

Suppose we reversed the ratios $R : R_1$ from 1,000 : 10 to 10 : 1,000—that is, unplugged 1,000 in C B and 10 in A C—then the above would have become

$$\frac{1,000 \times 7,582}{10} = 758,200.$$

Thus, by selecting suitable ratios in the arms, A C, C B, we measure accurately to parts of an ohm, or far beyond the total of the resistances of the instrument.

Although there are many forms of resistance box, they

Digitized by Google

are mostly made with a view to be used in the substitution for unknown resistances, or to form the known resistances in the arms of a Wheatstone's bridge. Fig. 9 shows a convenient form, as made by Messrs. Elliott Bros., with circular contacts.

EARTHING THE MIDDLE WIRE.

BY J. PIGG.

The probable more extended use of 200 to 250 volt incandescent lamps consequent on the success of the radical changes initiated by Mr. Baynes at Bradford, the raising by the Board of Trade of the low-pressure limit from 300 to 500 volts, and the consequent increase of pressure at consumers' terminals on three-wire systems, renders the question of earthing the middle wire peculiarly interesting at the present moment.

There are already indications that the subject is receiving some attention, and there has appeared in the technical Press an opinion from the electrical adviser of one of the chief insurance offices on the possibility of the full difference of potential being brought by a certain combination into one set of premises, although these premises are wired between the middle and an outer.

The hypothetical case cited, whilst not very likely to occur under ordinary circumstances, is possible, but it is by no means peculiar to a three-wire system, with either earthed or insulated middle wire. Every electrical engineer who has given attention to the requirements for effectually testing his circuits, is aware that he must take into account the possibility of both mains coming into more or less intimate contact with a comparatively well-insulated conductor at different points on the system, and that he must arrange his tests to detect such a fault.

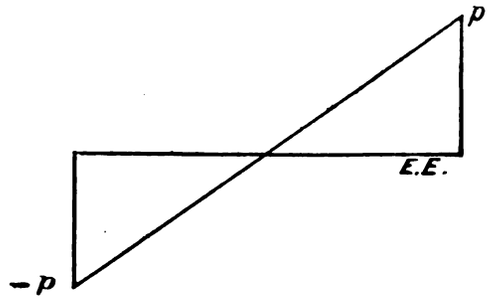

FIG. 1.

These faults, of course, are rare, but they may nevertheless be a source of danger. The combination put forward in the letter referred to is simply a variant of this class of fault, and the variation consists in the resistance between the two faulty points.

Whilst it would be foolish to assert that there is no danger to the individual from such a combination of circumstances, it is equally unwise to exaggerate the possibility of its occurrence or the impossibility of minimising the effect.

In any electrical circuit the total difference of potential is twice that between either conductor and zero, and the fall of potential through a circuit may be shown graphically by the well-known diagram (Fig. 1).

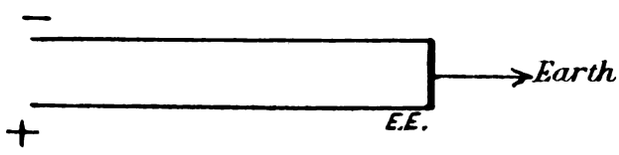

FIG. 2.

If the potential at one end of the conductor is P, the potential of the other end will be −P, and there will be a point at the centre of resistance, in a simple circuit, at zero potential. If the point at zero potential be put to earth, no disturbance of the electrical conditions of the circuit will result as long as the insulation of all other parts of the circuit is maintained.

If we consider such as circuit as Fig. 2 under the assumption that the resistance of all parts of the circuit to earth is infinite, with the exception of the zero point which is connected directly to earth, we see that there can be no leakage current either to earth or between the conductors.

Suppose that a leak develops on one of the conductors, as shown at *a* on Fig. 3.

If *a* is at a higher potential than the earth, some current, depending upon the resistance between *a* and A and the difference of potential, will pass between these points, and it by no means follows that the path of the leakage current will be "as the crow flies." A well-known proposition states that potential energy always tends to a minimum, and for this reason the path, or paths, selected are always such as tend to make the leakage current a maximum.

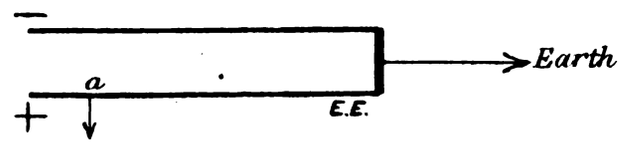

FIG. 3.

Hence such currents spread themselves over a considerable area, more especially when the distance between the points is considerable, and the resistance comparatively great.

Suppose, now, that in addition to the leak *a*, a leak, *b*, has developed on the other conductor, as in Fig. 4. The leakage currents are now less simple. There will still be leakage from *a* to A, and, in addition, there will be leakage from *a* to *b*. The latter leakage current tends to be greater than that between *a* and A, in consequence of the greater difference of potential existing between *a* and *b*, and the paths of the current between *a* and *b* are equally as devious, or more, as that from *a* to A.

The effects which may be produced by these stray currents are of great importance, and constitute the principal reason for any consideration of the matter of leakage. If the only reason for consideration was the loss accruing from leakage, the matter would not need to occupy much attention. Experience accumulated in practical working,

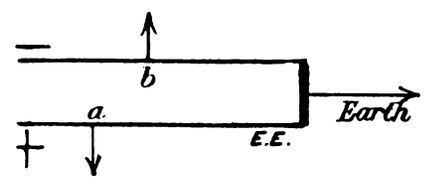

FIG. 4.

however, has shown that the loss due to leakage is an extremely small matter compared with the damage that may be done by the currents in their course from one leak to another.

The effects of the current are chemical, thermal, and magnetic, and to these must be added the effect upon the individual. If water is present at a leaky point on a conductor we may have an evolution of an explosive mixture of gases, or the metal of the conductor may be decomposed, or we may have both these chemical actions simultaneously, and the quantity of gas liberated and the decomposition of the conductor will be proportional to the strength of the leakage current. Electrolytic action may also take place at the surfaces of metals entirely unconnected with the circuit, but which are traversed by the stray currents in their course between two leaks.

If the leakage currents are comparatively large, their passage may, under favourable conditions, result in the outbreak of a fire at some point, and the danger is, in this case, proportional to the square of the leakage current.

If other electrical apparatus, using earth, exist in the neighbourhood of the stray currents, the latter may find their course facilitated by taking the line wire, or wires, as part of their path, and where delicate instruments are in use may cause considerable trouble and inconvenience.

The effects on the individual, although placed last, are by no means of the least importance. Whilst the current or difference of potential "that kills" may still be a matter of debate, and may largely depend on physical conditions, yet it is undeniable that the effects which may be produced

Digitized by Google

by even such a difference of potential as is now allowed as the limit of low pressure are unpleasant in the extreme, and may, to the debilitated, be serious.

Consider such a case as that shown by Fig. 2, with the earth connection at A removed. Any person standing on the ground and touching one conductor will experience, at most, the effect due to being charged to the same potential as the part of the conductor touched. If the earth connection at A was in existence when the wire was touched, a current would pass, the magnitude of which would depend upon the total resistance and the position, relatively to A, at which the wire was touched. Hence, for wires having infinite resistance to earth, the effect upon the individual is likely to be greater when an earth connection exists at A than without.

Consider next the effect on an individual who may touch either conductor with such a combination as Fig. 3. If he touches the leaky wire the effect on him will be less than it would if the leak *a* did not exist, and this lessening of effect is due to the existence of the earth connection at A. If, however, he touches the – wire the effect on him will be greater than if the leak *a* did not exist, and this effect will be the greater the more nearly to *a* he touches the – wire, and the less the actual resistance of the leak *a* to earth. Further consideration, however, shows that the effect will be less with the earth connection at A than without it, since some current must be passing from *a* to A.

Again, consider the effect produced under such circumstances as are shown in Fig. 4. Any person forming a connection between the + and – wires will have applied to his extremities a difference of potential which will be in some way proportional to the difference of potential existing between the wires, but which, as was found in the case of Fig. 3, is minimised by the existence of the earth connection at A. The actual difference of potential applied to his extremities will also depend greatly on the resistances of the leaks, *a* and *b*. If the resistance of the path, of which he forms a part, extraneous to himself is great compared with his individual resistance, the difference of potential at

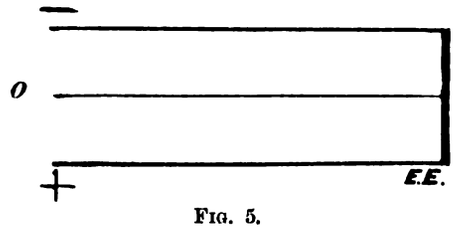

Fig. 5.

his extremities will be small compared with the total, and *vice versâ*. In any case, it is of importance to notice that the presence of the earth connection at A tends to minimise the effect produced.

A further careful consideration of Fig. 2 will show that the maximum stress across the insulating material is only that due to half the difference of potential existing between the wires, and the effect is the same whether the earth connection at A is existing or not. Consideration of Fig. 3 will show that the existence of the leak *a* will increase the stress across the insulating material of the – wire, but it also shows that the increase is less than it would have been had the earth connection at A been absent. Consideration of Fig. 3 also shows that the + wire carries less current than the – between the points *a* and A, and that the path of the leakage currents will concentrate in the earth connection at the latter point, and the whole current will pass through that portion of the apparatus connected between A and the – wire. Further consideration of Fig. 4 shows that a greater current exists in the + and – wires before reaching *a* and *b* than after, and that an inequality of currents will exist between the + and – wires between *a* and A and A and *b* respectively. Obviously, any safety device to prevent excessive leakage for such a defect as shown in Fig. 3 may be placed between A and the – wire, but a safety device for such a defect as in Fig. 4 must be placed somewhere near the source of generation. If the fault *a* (Fig. 3) existed alone, and the earth connection at A was not in existence, no leakage would take place. With the earth connection at A leakage does take place, and if the magnitude of the fault *a* is great, and the leakage current sufficient to actuate the safety device between A and the – wire, it will, by this action, notify its existence, which might otherwise remain unsuspected. If the fault *b* existed alone, the leakage currents from A to *b* would actuate safety devices placed between A and the + wire in exactly the same way.

Consider such a circuit as Fig. 5, and assume that all three wires have infinite resistance to earth. In this case we have Fig. 2 without the earth connection at A, and the effects are similar to those deduced in all respects. If faults develop on the + and O cables, leakage will occur. If faults occur on all three cables, the leakage currents will be similar to Fig. 3. In this case, however, we see that safety devices, to effectually protect against the effects of defects between apparatus and the middle wire, must be inserted at the point of junction with the middle wire.

Consider Fig. 6, and, assuming that none of the wires are purposely earthed at any point, but that leaks exist at *a*, *b*, *c*, and *d*, there will be leakage between *a* and *b*, *a* and *d*, *c* and *d*, and *c* and *b*. Each of these currents will split, and describe a number of stream lines, and the area affected by them in a large network may be much greater than the area covered by the network itself. The necessity for double-pole fuses, or similar devices, is also very apparent if faults exist on all three wires, as shown in the figure.

Now, suppose the middle wire to be purposely earthed at *e*. Leakage will now take place as before, but the area covered by the stray currents is restricted by the presence of the earth connection. If an additional fault developed at *f*, there would be some leakage from *f* to *d* and *b*. The leakage current between *f* and *b* would affect the fuse on the middle wire only, and it is therefore still necessary that double-pole fuses should be used to protect the branch.

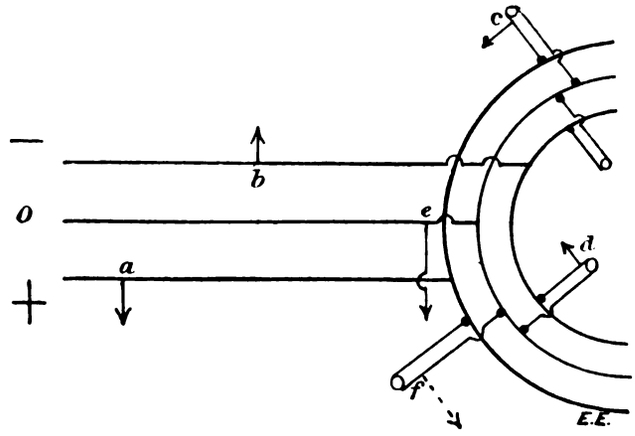

Fig. 6.

If the middle distributor is earthed throughout its length, the area covered by stray currents due to defects in the distributors is very greatly reduced, but the stray currents due to defects in the feeders are comparatively unaffected. One result, however, of earthing the middle distributor throughout its length is that single-pole fuses, placed between the apparatus and the outer, are required only. Fuses between the apparatus and the middle wire are superfluous, since leaking currents passing through defects between the apparatus and the middle wire must pass through the fuse on the outer.

Suppose, however, that O is entirely uninsulated throughout its whole length, and the outer + and – wires have infinite resistance to earth. The case is again analogous with Fig. 2. The extreme difference of potential applicable to an individual in connection with the earth, and touching one wire, is only half the total difference of potential existing between the + and – wires. The stress upon the insulating material is also that due to only half the total difference of potential, and if the current in the + and – wires is the same throughout their length there will be no leakage currents. If the balancing is not perfect, and current passes through O, there will be leakage currents, but their magnitude and range will be limited by the maximum difference of potential between the ends of O, and not by the maximum difference of potential between

Digitized by Google

the outers. This difference of potential may be reduced to any extent, for any given degree of unbalancing, by increasing the section of O.

If Fig. 6 is considered under the assumption that the wire O is perfectly earthed throughout its whole length, it will be found that the area occupied by leakage currents is greatly circumscribed. Leakage currents will more readily pass from *a* to O than to *b*, *d*, or *f*, and if the + and – wires experience no other resistance to O than that of their respective insulating material, the area covered by leakage currents will be still further restricted, the disturbance of other electrical circuits and the thermal and electrolytic continued throughout the system, the chance of such a combination as that referred to in Mr. Snell's letter would be very remote indeed.

As to how far electrolytic action on the uninsulated middle wire would affect the working in the course of time it is scarcely possible to say. Cases have been cited which tend to show that the danger is more imaginary than real. In any case it would seem necessary to specify the maximum allowable difference of potential between the ends of the middle wire. Moreover, it would seem possible to partially shield the conductor from electrolytic action by earthing through earth rods or plates. Electrolysis would then

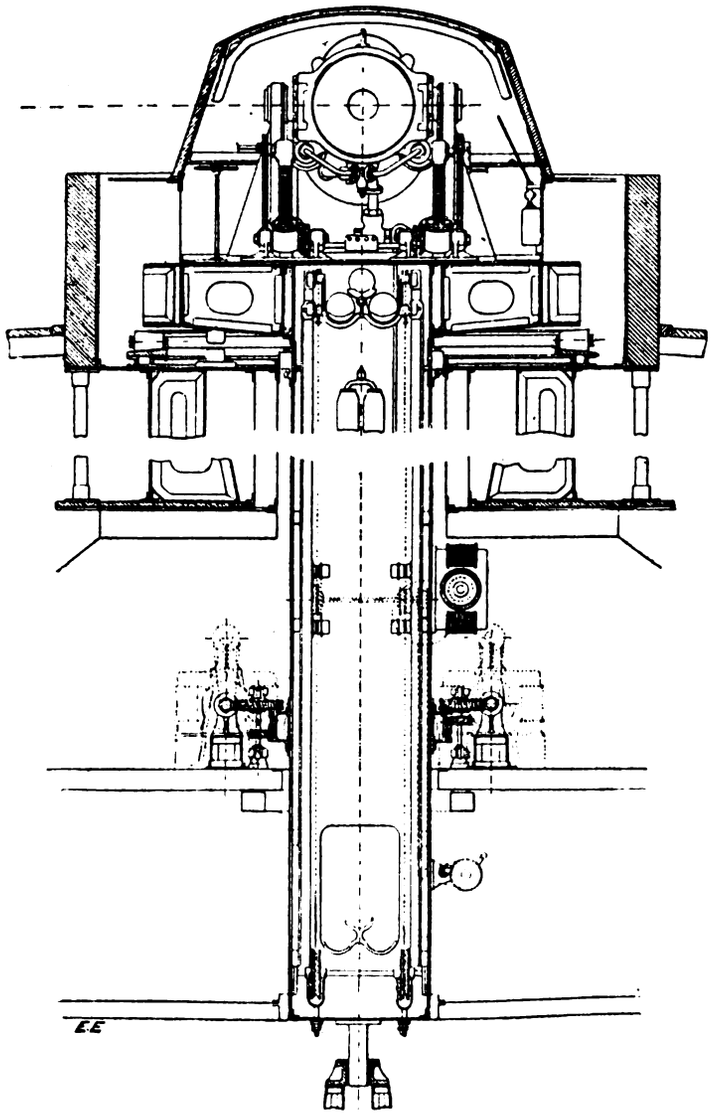

FIG. 1.—Section of a Turret on the Cruiser "Capitan Prat" showing Electric Motors.

effects will be diminished, the danger to the individual will be less than if the middle wire was insulated, and the number of fuses required will be diminished by half.

The whole question would seem, from the considerations adduced, to turn on the maintenance of the insulation of outer + and – wires. If this insulation can be maintained, no advantage results from the earthing of the middle wire. If the insulation cannot be maintained, and it seems difficult to conceive it possible under all circumstances, there would seem very substantial advantages to be gained by earthing the middle wire.

The most suitable method would seem to be to use two concentric mains, the outers of which are uninsulated, and which would, jointly, constitute the middle wire. The outer uninsulated conductors of both concentric mains would be connected together, electrically, at short intervals; so that the whole section of the middle wire would be available for currents passing through it. Under these conditions any defect would show itself at the fuses at once, and there would be practically no stray currents except those due to difference of potential between the ends of the middle wire; and if this class of wiring was occur principally at the earth-plate, and the middle wire would be thereby protected.

ELECTRIC TURRETS ON THE CRUISER "CAPITAN PRAT."

The following description of the turret on this warship is abstracted from an article in *L'Electricien* by G. Dary. The question of applying electric energy for the manœuvring of large guns has been under consideration since 1885. About that time the English Admiralty and the similar department in the United States of America ordered experiments to be made to find the most simple and effective means of adapting electromotors for the training of guns and for the ammunition hoists. Messrs. Symon and Maxim were early in the field, and invented a cannon which could be easily operated by one man. This was worked by one motor only, and was also fired electrically. The Chilian Government, when ordering a new cruiser, invited several European designers to submit

Digitized by Google

plans to an international commission. After careful examination this commission gave this important work to the Société des forges et chantiers de la Mediterranée. The plans were those of Mr. Lagane, who is chief engineer to the above company.

The cruiser "Capitan Prat," which was launched in 1893, is 328ft. long by 60ft. 9in. beam, with a draught of 21ft. 8in. Its tonnage is 6,800. Its artillery consists of four 9½in. guns placed in barbettes fore and aft, and one on each side of the lighting purposes, and the switchboards are so arranged that the machines can be used on either circuit. Duplicate circuits are also run to each turret and gun.

On the shaft of each motor is placed a worm gearing into a worm-wheel with a vertical axis. This shaft carries a pinion gearing into a spur wheel concentric with the central tube of the turret, and which drives it through a spring attachment. This prevents sudden shocks. The switch gear is placed under the charge of the chief gunner,

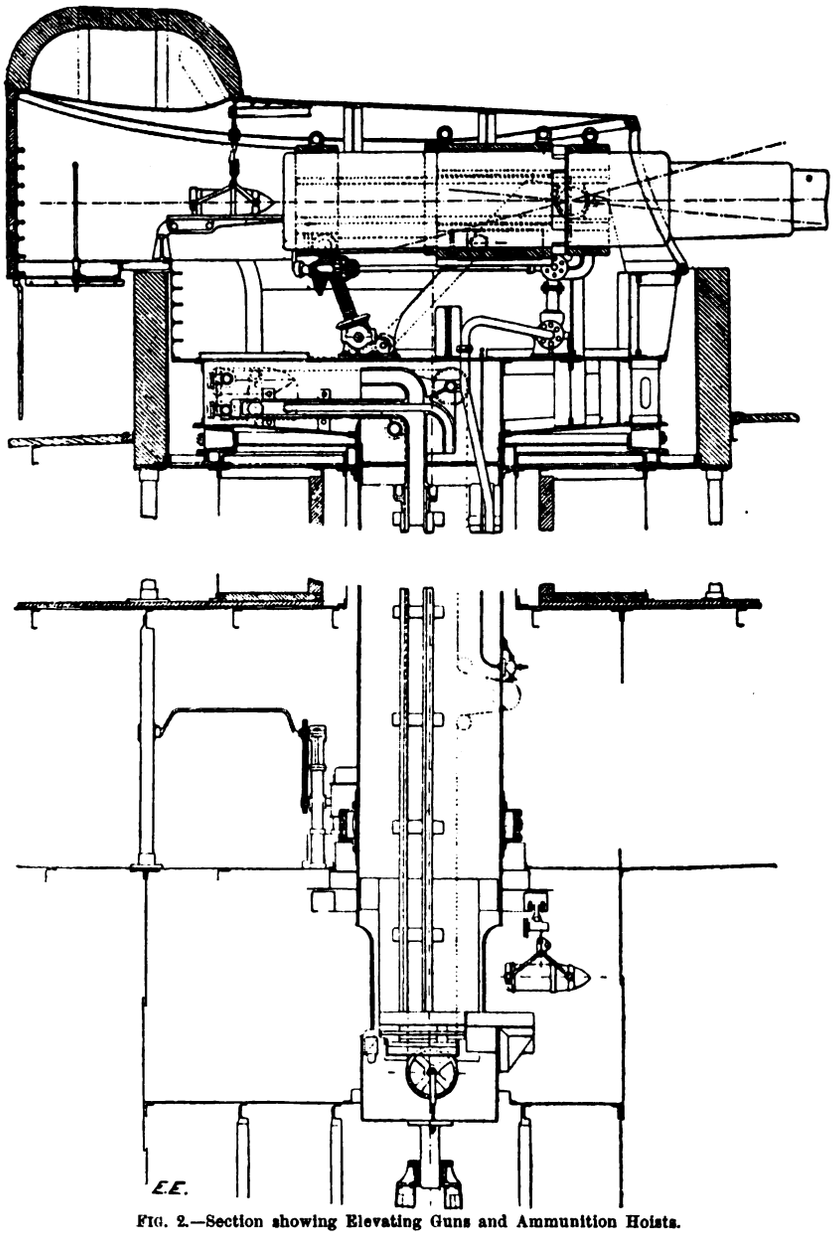

FIG. 2.—Section showing Elevating Guns and Ammunition Hoists.

vessel, eight 4¾in. quick-firing guns, 16 Hotchkiss guns, five gatlings, and four torpedo tubes. The construction of the turrets will be readily seen from the illustration. Two motors connected parallel on the electric mains are placed a little distance from the central tube on a special base-plate. They work by means of spur gear, the one driving the revolving gun platform, and the other the elevating gear. The first motor is capable of developing 650 foot-pounds per second with 15 amperes, and the other 565 foot-pounds per second with 12 amperes. This last power is more than sufficient for the purposes to which it is applied. But to turn the barbette which contains and protects the gun, the power of the first motor had to be augmented to 2 h.p. The distribution and regulation of the current to this motor is effected by hand rheostats placed on the moving platforms. The gunner is thus able to train the gun without taking his eye off the sights.

The current is supplied from four dynamos coupled two to each of two engines, and placed in the engine-room. Each dynamo can give 500 amperes at 70 volts, to be applied at the same time to work the four large guns and the eight smaller ones. Two other similar sets are used for

It consists of a horizontal circular plate, on which are engraved the numbers 1, 2, 3, and 4 on each side of zero, which is the normal position of the handle. These divisions give different speeds of the motor in either direction. Thus, to turn this gun and turret through 270deg. it takes

1 minute	27	seconds	on the	first position.
1 „	17	„	„	second „
1 „	12	„	„	third „
1 „	4	„	„	fourth „

When the correct position has been roughly found, the handle is let go and it returns to zero automatically. The final adjustment is then obtained by means of two keys similar to those used on the Morse instruments. With the fine adjustment obtained with this second arrangement, impulses of $\frac{1}{10}$th to $\frac{1}{15}$th of a degree can easily be obtained. The energy acquired by this great weight (some 87 tons) moving even at a slow speed has to be quickly absorbed when the gun is in the correct position. To do this, and to prevent the gun moving on when the current is switched off, there are brakes provided, but the principal stopping

Digitized by Google

effort is obtained by short-circuiting the motors. This short-circuiting is effected automatically. The lifts for the ammunition are worked by separate motors fixed on plates riveted to the central tube, and turning with it. The ammunition carrier is worked by an endless chain, which is automatically stopped when the carrier is at the extremities of its course.

The author states that the gear works most satisfactorily, and that much time is saved by it.

TELEPHONE EXCHANGES AND THEIR WORKING.*

BY DANE SINCLAIR, MEMBER.

In introducing this subject I find that, to give you anything like a clear idea of the working of telephone exchanges as they exist in this country, it will be necessary for me to refer to a few fundamental principles underlying all telephone exchange work, which, however, have been previously explained in journals, text-books, and elsewhere. In all telephone systems there are three branches into which they may naturally be divided—viz., (1) the line wires connecting subscribers' offices to exchanges; (2) the instruments in subscribers' offices; and (3) the switchboards in the exchanges.

With reference to the lines, it is not my intention here to say much in regard to them; although, indeed, the lines now used for telephonic purposes differ very greatly from those formerly used for telegraphic work. It was not until the introduction of the telephone that such subjects as the static capacity and self-induction of lines received so much attention in other than submarine telegraph work. In telephone work, however, these points are of the very highest importance, and necessitate a large amount of attention. We have arrangements working on our telephone lines which, at first sight, would have appeared to the old telegraph engineer to be the worst that could possibly be devised. I have made some experiments on telephone lines, and, under certain conditions, have obtained better speaking results over a line 40 miles in length, on which there was a series of earths, or leakages, than could have been obtained with a well-insulated line. The same applies to metallic circuits, but in this case the leakage is from the outgoing wire to the return. This subject, although interesting, is, however, outside the scope of my present paper.

Broadly speaking, all the calling instruments now used in this country in subscribers' offices are those known as the magneto pattern, and there is fitted along with each a transmitter, battery, and receiver, the whole forming a complete set. It is, however, the switchboards at the exchanges that I wish specially to bring before your notice to-night. The diagram at Fig. 1 shows the connections which, with certain modifications, are made on all kinds of switchboards. The apparatus includes a line jack, marked J, and an indicator, marked I, through both of which the circuit passes either to a general earth wire, or, in the case of metallic circuits, to a return wire. I may explain that what is called a "jack" is that part of the apparatus into which the connecting plug is inserted. When any two lines are to be connected together, two of these plugs are inserted into the two jacks of the lines concerned, the plugs being connected together by a flexible conducting cord. It is our usual practice in this country for small exchanges—of, say, under 200 lines—to make up the switchboard in sections of 50 lines. The drawing at Fig. 2 shows the type of section which has been adopted by the National Telephone Company for general use in these small exchanges. In its main principles it is the same as other small standard boards, but special attention has been given to the details; facilities have been provided for connecting the line wires to the switchboard, and all the working parts have been covered so as to exclude dust as much as possible. A further reference to Fig. 1 will show that here, as before described, the line passes through the jack and indicator and back by the return wire. Cords, similar to the one already mentioned, are fitted on a shelf, each cord having a pulley and weight to bring it back to its proper place when out of use. A ring-off indicator is also provided, which can be put in bridge across the cord by means of the key designed for that purpose. This key is shown at Fig. 3†, and by it the operator can also throw her telephone into or out of circuit as required. A separate pair of keys is provided to enable the operator to ring on either of the lines she is connecting. The ringing current is, as a rule, produced by a small generator driven by an electric or other motor. These listening keys and ringing keys are now universally used by the National Telephone Company, and are all of the standard patterns shown. When a subscriber turns the handle of his generator the shutter of his indicator in the exchange drops and shows his number. The operator then inserts one of the plugs of a double cord into the jack belonging to this line, and asks the subscriber what he wants. When this information is received, the operator inserts the plug at the other end of the cord into the jack of the line wanted, and completes the operation by turning the lever of her key, which cuts her telephone out of circuit and brings in the ring-off indicator. This indicator, as before mentioned, is now connected across the line in bridge in the case of metallic circuits, or tapped to earth in the case of single wires. This indicator is of a special type, being wound to a resistance of 1,000 ohms, and placed inside a tube of soft iron, so as to give it large self-induction and cause great impedance to the passage of telephone currents, which are, of course, of high frequency. The object of this indicator is to show the operator when subscribers have finished their conversation. When this signal is given to the operator, the plugs are withdrawn and everything restored to its normal condition. As the subscribers' indicators are cut out of circuit when their lines are connected as described above, they are of the ordinary type, and are wound to a resistance of 100 ohms. In addition to the type of board already mentioned, shown at Fig. 2, we have used in this country very largely, for small exchanges and for private installations, a class of switchboard known as the "single-cord" board. In this pattern of board a cord and plug are provided for each line, and, as shown on the drawing (Fig. 4), the lines come to the outer springs of the jacks, and, without breaking, pass to the cord and terminate in the plug. In addition to this, a high-resistance indicator, of the same type as the ring-off indicator previously described, is provided for each line. To make a connection the plug of the line of the calling subscriber is inserted into the jack of the line wanted, leaving the indicator of the first line in circuit, and, as will be seen in Fig. 4, the indicator of the second line is cut out of circuit. For working this class of board, the operating instruments is provided with a plug for answering the calling subscriber and for ringing the subscriber wanted.

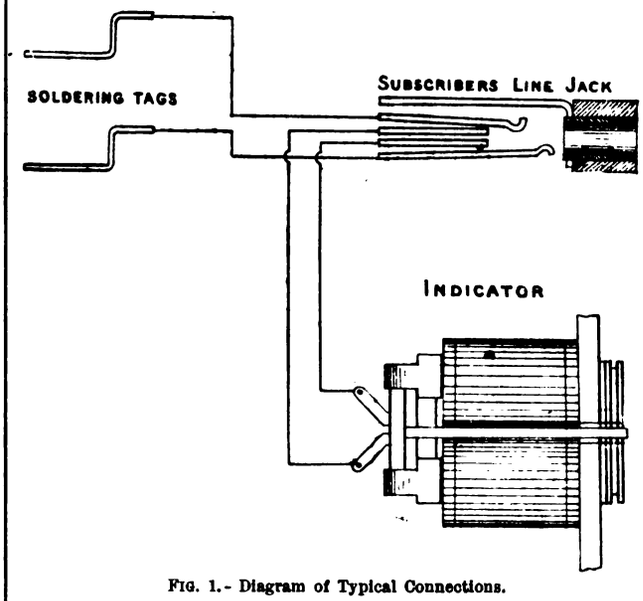

FIG. 1.- Diagram of Typical Connections.

It will be readily understood from what has been said that as exchanges increase in size the switchboards become too large for the operators to be able to reach to make all the connections. In the earlier days wires were run between the various sections of the board for the purpose of connecting the different groups of subscribers' wires together. At this point commenced the difficulties of telephone exchange work, because there was no certain method of showing to the operators in the exchange when any subscriber's line was engaged, and also because the first operator had not complete control of the connection, and, consequently, it was liable to be interfered with by the second operator. In practice this became a very serious trouble. A remedy was found by our friends on the other side of the Atlantic, where they had to deal with the question of large exchanges earlier than we in this country. To overcome the difficulty they invented what is known as the "multiple" board, the possession of patents for which must have given the owners very considerable satisfaction, as well as yielded them enormous profits. In this connection I may mention that the multiple system was independently invented by an employé of the United Telephone Company, but subsequently to the date of the American patent. The multiple switchboards used generally in this country are made up of the required number of sections, each containing all the apparatus necessary for 200 lines. Each section is 6ft. 6in. in length, and is subdivided for four operators, each

* Paper read before the Institution of Electrical Engineers last night.

† Figs. 3, 4, and 5A will be given with the remaining portion of this paper.

Digitized by Google

having 12 pairs of connecting cords, with the usual equipment of listening and ringing keys of the type shown at Figs. 3 and 5A. In addition to the full equipment of apparatus necessary for 200 lines, each section is also fitted with jacks, through which all the lines in the exchange pass. On this principle the number of jacks necessary in an exchange increases in an amazing manner. For instance, an exchange with 400 subscribers' wires would require only 800 line jacks—*i.e.*, the 400 lines in the exchange would come to jacks on section No. 1, and be repeated on section No. 2; but if we consider an exchange of 5,000 subscribers' lines under similar conditions, we find that there would be 25 sections of 200 lines each. As in the case of the two sections mentioned, the line jacks would be repeated on each of the 25 sections (5,000 on each), making a total of 125,000 line jacks. In practice every exchange is provided also with junction wires to other exchanges, and many of them with trunk wires to other towns. The junction wires are divided into two approximately equal groups, one carrying tho outgoing and the other the incoming traffic. To render the outgoing junctions accessible to all the operators, they are, like the subscribers' lines multipled on every section. Incoming junctions do not require to be multipled, but special sections are provided for working them, and these also contain a multiple of all the subscribers' lines. As it is found in practice that an operator cannot attend to more than 25 of these junction lines, each section, with four operators, will accommodate 100 junction lines. *(To be continued.)*

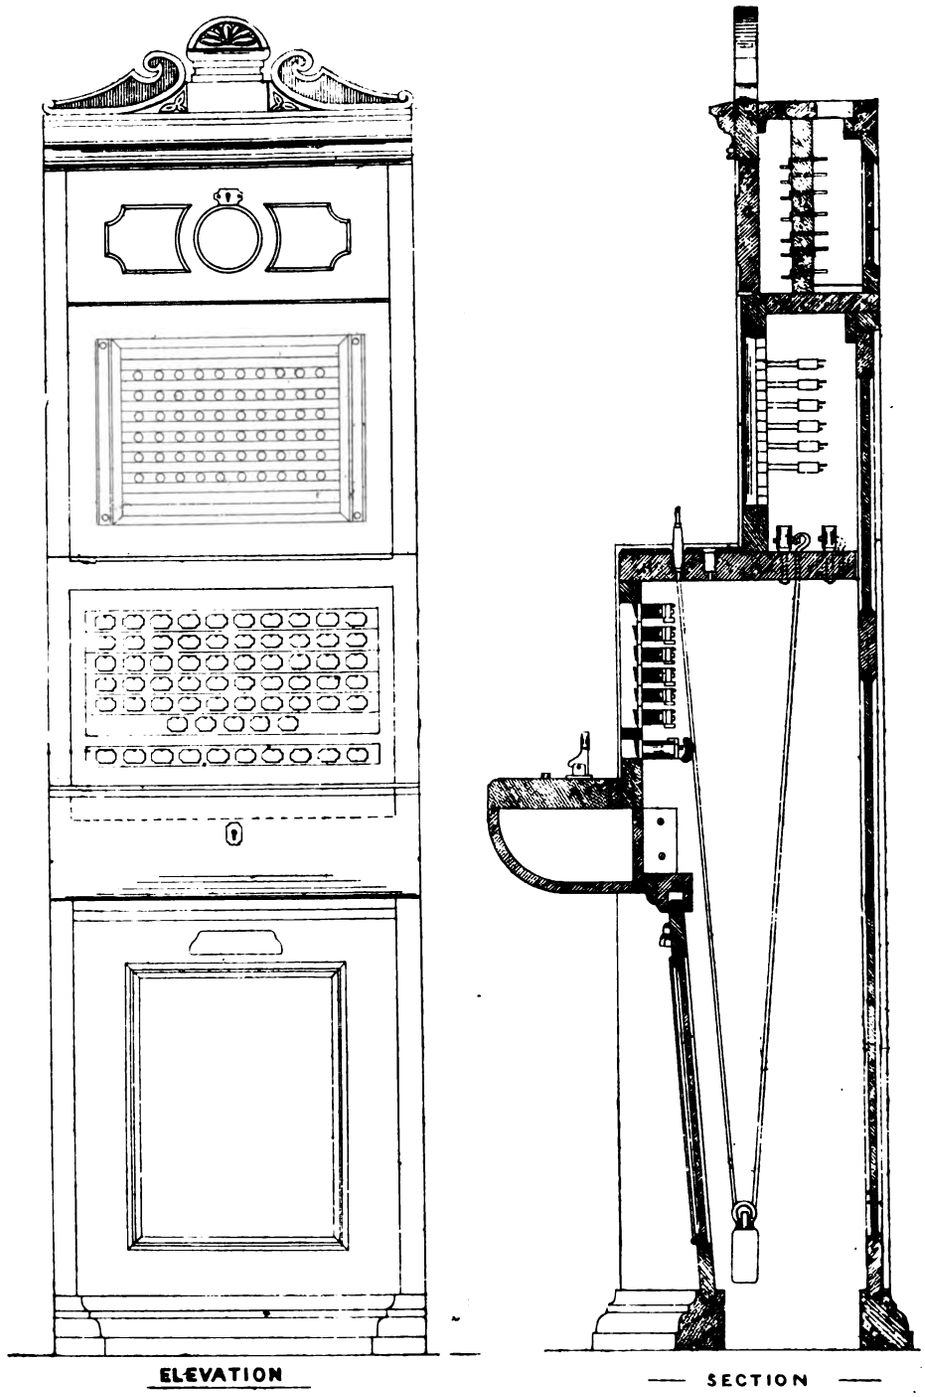

FIG. 2.—Switchboard for Small Exchange of Fifty Subscribers.

INSTITUTION OF ELECTRICAL ENGINEERS, Mar. 12.

At last night's meeting of the Institution the following candidates were balloted for:

Members.—Thomas Topham Hardaker and R. W. Weightman, Government Telegraph Department, Pietermaritzburg, Natal.

Associates.—Gabriel Andreoli, "The Acacias," 147, Cold Harbour-lane, S.E.; Captain Mossom Archibald Boyd, R.E., 3, The Esplanade, Plymouth; Ernest James Cochrane, care of Westralian Electric Light Supply Company, Coolgardie, West Australia; Philip Henry Dawe, 4, Cranbury-place, Southampton; Léon Gaster, 37, Maida-vale, W.; Harold Hastings, 5, Oakley-street, Chelsea, S.W.; Samuel Thomas Pemberton, 36, Hornsey Park-road, Hornsey, N.; Edward Gould Tillyer, "Dunedin," Mottingham, Eltham; William Robert Clapcott Walkley, 67, The Grove, Hammersmith, W.

Students.—John Arthur Hotham Clifford, St. John's Hill, Ellesmere; H. F. Hesse, 23, Montague-road, Richmond, Surrey; Reginald Wilson Gauntlett, 23, Dartmouth Park Hill, N.W.

Electrical Engineering in Hungary.—An electric power transmission plant is being installed by Messrs. Siemens and Halske, of Vienna, at the gold mine of the Ruda-Zwolfapostel Gowerkschaft, at Brad, near Deva, Hungary.

THE GOVERNMENT AND ITS CONTRACTORS.

It may seem like thrashing a dead horse to call attention to questions pertaining to governments, contractors, and working drawings. The subject, however, is both important and painful. Quite recently questions have been asked in Parliament and communications have appeared in the papers in connection with certain working drawings relating to torpedo catchers. It seems the custom of the Government, or at any rate the Admiralty, is to insist upon a set of working drawings from the contractors. When a new departure is being made this custom works out disastrously to the contractors, for the subsequent action of the Department is to hand the working drawings over to competitive contractors, and upon them to invite tenders. It is probably an exceptional case for a first order to pay, especially when the contractor has largely to be a designer and inventor. Take the especial case that has caused so great a commotion. The builders of fast-speed ships in the first instance did not work to rigid specifications; they suggested and made alterations both to vessels and machinery, with the result that something superior to anything existing before was produced. Having achieved this success, not by merely building to specification, but by the use of brain power, skill, and experience—by the use, in fact, of items that cannot be scheduled at so much per hour or so much per weight in a list of prices, the contractors naturally expect that, having obtained what was wanted, their efforts would be recognised by repeat orders. Nothing of the sort, however, happens. The talented men see their designs sent broadcast to competing firms, and these firms are asked to tender for the repeat work. The chances are largely against the original builders getting the further contracts, and hence against their getting any return for their original work. If specifications and drawings were always sent out in a perfect state from the Admiralty, there would be little to complain about. The original work would then be done by their own engineers, and the contractors would be merely contractors, and nothing else. We should hardly have any reason to complain of this state of things were the matters under discussion restricted to ships and steam-engines only, but, with all reserve, we are bound to state that the trouble goes far beyond—it is as wide as the requirements of the various departments. There is hardly a single matter of detail, say, in regard to electrical apparatus, that has not been largely benefited by the work of contractors. Their skill, knowledge, and experience has been used in order to produce the apparatus. It is no mere fulfilling an order that we refer to, but the successful construction of a new piece of apparatus. The construction may fail; on the other hand, it may succeed, and the success may be due wholly to the work of the contractors. Just what has happened in regard to fast-speed ships has and does happen in regard to electrical apparatus. The working drawings for further requirements are sent to other than the original contractors, and now that the thing can be specified with exactness, every

Digitized by Google

firm receiving the specification is reaping the benefit of the original firm's work to that firm's loss. It is a very easy matter to show the unfairness of such a system, but it is as difficult a matter to suggest an efficient remedy. The Government cannot very well guarantee to restrict its purchases to one firm only. That remedy would be worse than the evil. We can only suggest a give-and-take method. The large Government departments ought to be able to command the unbiassed views of experts. The experts ought to know whether a suggested construction is in the shape of a new departure or not; they ought also to be able to appraise a value to the successful construction of new apparatus without being niggardly or lavish. The military and naval authorities of the kingdom are compelled to act in a progressive manner, and frequently in an arbitrary way, but there is no reason why they should not act justly. No one can defend the obtaining of original working drawings to the detriment of the designer. The country does not wish to obtain anything without suitable remuneration, and it is therefore for those in authority to enquire carefully into all these questions and arrange for just consideration to be given for work done.

REVIEWS.

Applied Magnetism. By J. A. Kingdon, B.A. H. Alabaster, Gatehouse, and Co., 22, Paternoster-row, E.C.

This book, which is to serve as an introduction to the design of electromagnetic apparatus, is one which can be highly recommended to all students, and to those who have only a practical knowledge of their profession. The matter is treated in a lucid and complete manner, and bears the stamp of original thought. The following is the progressive order of the information given. Commencing in the first chapter with a description of the general principles of magnetism, the author passes on to consider electromagnetic units, magnetomotive force, tractive force, generation of E.M.F., and qualitative magnetism, before broaching the general applications. The remaining two-thirds of the book is devoted to the practical use of magnetism, and gives the general formulæ for the design of alternators, dynamos, and other magnetic machinery. The matter is necessarily condensed, but this is a distinct advantage when the reader uses the book as a preliminary treatise before specialising. The question of sparking at the commutator is well gone into, but, although the author's grasp of the subject is clear, we hardly like the following sentence on page 185, that "the essential point in the design of a dynamo is to effect the commutation under such conditions that the commutated coil has no self-induction." The matter is explained afterwards, but the fact that the self-induction must be neutralised is not conveyed by the above statement. Another point overlooked in the calculation of the hysteresis loss in the core of an armature is the fact that the maximum induction is considerably higher than the mean when the dynamo is loaded. The main point, however, in which we think the author should have used more care is in the choice of his symbols. His treatment is distinctly orthodox, but his symbols are not. Thus, he calls a C.G.S. line a mag., but uses M for magnetomotive force. Again, R is used for resistance and revolutions per minute in different parts of the book, so that the student in his list of formulæ cannot tell which is which. Afterwards r is also added for revolutions per minute. Again, f is used for both magnetic flux and for frequency, and hence a reader could obtain an f^2 in the transformer equations. To avoid this the author uses p for frequency, although this letter in other places signifies the number of poles in an alternator and also the power in watts. The letter C is ubiquitous in its application, but the climax is reached when C = the current in a wire in the armature, and the horse-power is then $\frac{2CE}{746}$.

One other example will suffice, and that is the use of L, the accepted term for self-induction, or magnetic reluctance. We know that an intelligent student is not hampered while confining his studies to this volume only by these uses of the common symbols, but the redundancy of meaning is even then confusing, and his further studies would in any case be more difficult. The printing of the book and the illustrations are excellent, and the collection of the symbols and formulæ at the end would be most useful with a rearrangement of symbols.

Electric Wiring. By Russell Robb. Macmillan and Co, New York. 10s.

This well-edited book is intended for the use of architects, underwriters, and the owners of buildings. The author has not therefore attempted to deal fully with all the principles of electrical engineering, but has endeavoured to supply an everyday knowledge which will certainly be useful to the people for whom the book is written. The national code of rules for electric wiring are given in detail, followed by an explanation of the *raison d'être* of each rule. Hence the book is much more useful to America, as 123 pages out of 177 are devoted to these rules, which are not applicable in England. The first four chapters, dealing with the various electrical units, the proportioning of wires, and systems of distribution, are more universally applicable. Some of the analogies used are rather strained to meet the case in point, but, on the whole, the reasoning is concise and clear. We recommend this book to those who wish to understand the regulations in force in America, where wider latitude is allowed in wiring construction than in England.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

March 27, 8 p.m.—Students' meeting. "Closing a Dock Entrance for Repairs," by J. S. Wise, Stud.I.C.E.
March 31, 8 p.m.—Ordinary meeting. "The Tampico Harbour Works," by Dr. E. L Corthell, M.A., M.I.C.E.

Institution of Electrical Engineers.

March 28, 8.30 p.m.—Students' class. Visit to Amberley-road, Manchester square, and Sardinia-street central stations of Metropolitan Electric Supply Company. Assemble at Amberley-road.

Institution of Junior Engineers.

March 28, 7.30 p.m.—Conversazione at Westminster Palace Hotel.

Royal Institution of Great Britain.

March 27, 9 p.m.—"New Researches on Liquid Air," by Prof. Dewar.
March 28, 3 p.m.—Last lecture on "Light," by Lord Rayleigh.

Physical Society.

March 27, 5 p.m.—At Burlington House. "The Electromagnetic Effect of Moving Charges," by G. W. Morton. "The Edison Effect," by J. A. Fleming.

King's College Engineering Society.

March 27, 4 p.m.—Terminal business meeting.

Electro-Harmonic Society.

March 27, 8 p.m.—Smoking concert, St. James's Hall Restaurant.

City of London Electric Lighting Company, Limited.

March 31, 7.45 p.m.—The staff's fourth annual Bohemian concert, Cannon street Hotel.

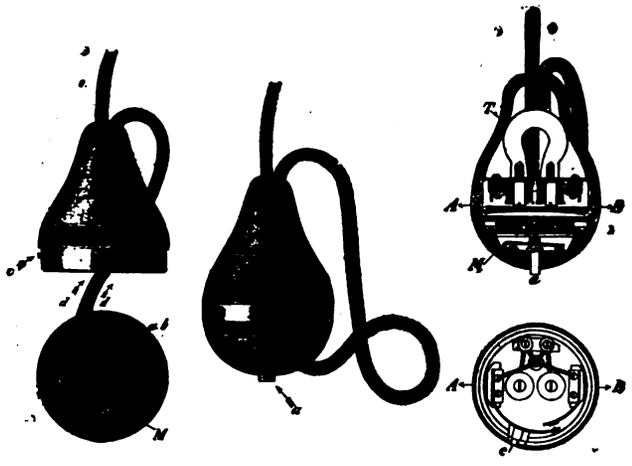
SMALL DOMESTIC TELEPHONES.*

The firm of Töpffer and Schadel, Berlin, now construct for small installations miniature telephones, which, if they act as well as they are said to do, ought, by reason of their handiness, to be of service for hotels, hospitals, factories, ships' cabins, etc. Designed to look like the pear presses

* From *L'Electricien*.

Digitized by Google

of electric bells, they do not disfigure the decorations. The telephone will be very useful for invalids, who will find it handy when they need to call for assistance. The apparatus, as represented in the above illustrations, can be suspended anywhere. It is cased in vulcanite, wood, or aluminium, and weighs about 100 grains. It is shown in two sections, one axial, the other through A B. The upper part contains the telephone, T; the lower part the microphone, M. They are connected by the flexible wire, *d d*, or they can be joined up separately if wished. The perforated plate, *b*, serves to protect the microphone; the button, *a*, rings a bell. The telephone, T, is composed of a powerful horseshoe magnet with bobbins of wire on it. The microphone is formed of a corrugated carbon disc and grains of carbon. When the receiver and transmitter are joined, contact is made by pressing the little button, C, which puts the telephone in circuit and rings the bell. This done, the two parts are separated; the ear is placed to the



telephone and the mouth to the microphone, and conversation can be carried on, the contact, C, automatically retaining the telephone in the circuit.

THE REGULATION OF PRESSURE AND THE REDUCTION OF LIGHT-LOAD LOSSES IN ALTERNATING-CURRENT SYSTEMS OF ELECTRIC SUPPLY.*

BY E. W. COWAN AND ALFRED STILL.

On account of the greater facility with which the pressure can be maintained on a system of distribution when the supply is a high-tension one, provision for its regulation has come to be somewhat neglected in this country. The standard of permissible variation of pressure with a low-tension system has not been a high one, and because with a high-tension supply it has been found easy to improve upon this, few efforts have been made towards the attainment of a higher standard. But with the heavier loads of to-day, and the advantage of our more complete knowledge of alternating currents, we should not rest satisfied with so low a standard; and complaints from consumers connected to the tail end of long distributors of the falling off in their light at times of heavy load when its full brilliance is most desired, should belong to the history of the past. We can do better, and we ought to.

The object of the first part of this paper is to set forth what we believe to be the best methods of maintaining constant pressure in all parts of a distribution system under varying conditions of load. The first point to which attention must naturally be paid is the arrangement of the mains and transformers. This subject has already been dealt with to some extent before this society by Mr. Clirehugh and Mr. Rider, but as each district must be considered on its own merits, it is not possible to formulate any definite rules. There are perhaps four systems open to us: (1) high-tension distributors with transformers on consumers' premises; (2) feeders in connection with high-tension distributors and transformers on consumers' premises; (3) feeders with transformers in sub-stations and low-pressure distribution; (4) feeders with transformers in street boxes, and both high and low tension distributors. From the point of view of the subject of this paper—viz., the regulation of pressure—the first of the above systems is the worst and the last one the best. It is on the relative advantages of the third and fourth systems that we should like to offer a few remarks.

Sub-stations with banks of transformers have become very popular; but we are inclined to think that their advantages are somewhat overrated, and that a cheaper, and in some respects more efficient, arrangement is to space out the transformers under the footway in the manner indicated at D, in diagram No. 1. With this arrangement a much better regulation can be obtained than the low-pressure distribution system shown at C. It has the further advantage of simplicity in the first laying of the mains when the distribution of the load is uncertain. Most of us have been surprised when a station has been running for some time to find that our lamp connections have not distributed themselves according to our expectations, and that we have heavy cables lightly loaded and light cables heavily loaded. With this system, it is simple and inexpensive to lay both high and low tension cables of large enough capacity for the ultimate requirements of the district. The transformers, which may be of uniform size, are fixed according to the position and amount of load as it arises, the final result being that

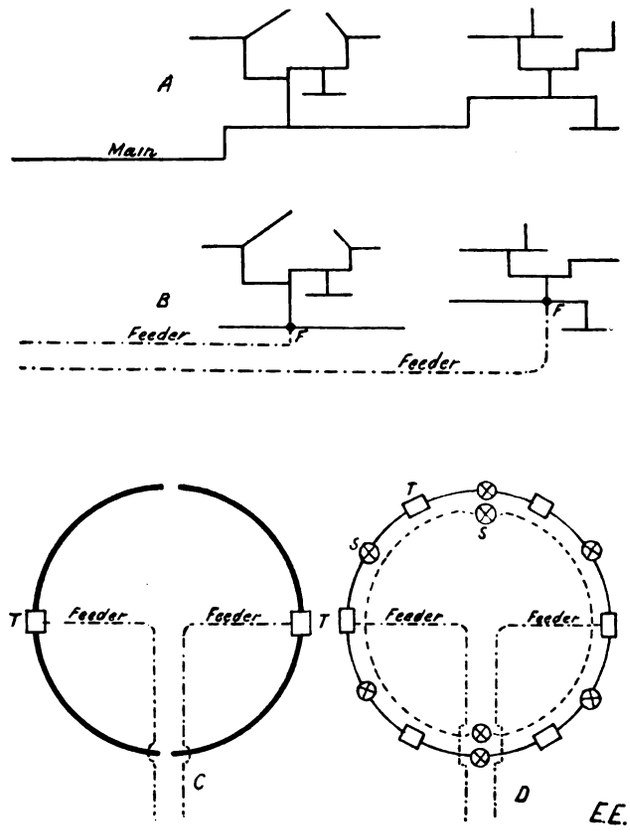


DIAGRAM NO. 1.

transformers are close together where the load is heavy and comparatively remote in those positions where the demand is small. It may be argued that many transformers of a small size cannot be so efficient as a small number of larger size; but 12 to 15 kilowatt transformers may have a very high efficiency, and they are more readily handled than the very large sizes often fixed in sub-stations. If underground switches are arranged to connect the low-tension service mains of one transformer to those of the transformers on each side of it when required, it will be possible to remove a transformer without interfering with the supply. And if similar switches are fitted at intervals in the high-tension main, a fault in the cable can readily be cut out and the supply continued in the whole district fed by this main, with the exception of the particular length which contains the fault. Such underground switches can be made at a low cost, and will work quite satisfactorily. Whatever system may be adopted, it is certain that feeders will form part of it, and the important question arises as to what cross-section they should have. Apart from the question of regulation, there can be no doubt that they should be proportioned in accordance with Thomson's law. But here a difficulty arises: the loss of pressure will be frequently be so great that at times of full load uniformity of pressure cannot be maintained at the feeding points unless all the feeders are of the same length and subject to corresponding fluctuations of load, a condition which does not obtain in practice. It follows, therefore, that a regulating device must be connected to each feeder, preferably at the generating station end, or inequality of pressure at the feeding points will result; the other alternative being to lay feeders, which are uneconomical on account of their large cross-section and corresponding

* Paper read before the Northern Society of Electrical Engineers, March 23, 1896.

Digitized by Google

first cost. Mr. Crompton, we think, makes too much of "efficiency of distribution," this being a question which cannot properly be dealt with except in connection with first cost.

We propose now to describe a simple graphic method of determining the sectional area of feeders according to Thomson's law, as the usual formula needs some modification to adapt it to cables of which the insulation bears a large proportion to the total cost, and which do not carry a constant load. We will afterwards deal with the various regulating devices which are available at the present time for compensating for the drop on the feeders.

Feeders.—The most economical cross-section for a feeder depends upon two things only: the first cost of the cable and the cost of production of the energy lost in it on account of its ohmic resistance. Thomson's law, which takes into account the annual cost of the watts lost in the conductor, and the allowance for depreciation and interest on first cost of the cable, may be expressed as follows: The most economical section of a conductor supplying electric current to a distance is such that the annual allowance for interest and depreciation on original cost of the cable will be equal to the annual cost of the energy wasted in overcoming its ohmic resistance. The cross-section should therefore be determined solely by the current which it has to carry, and not by its length, or an arbitrary limit of the percentage full load drop in pressure—the drop, even if considerable (and it is not likely to be so on a high-tension system), must take care of itself. There are possibly two reasons why Thomson's law is not more generally followed in calculating the sizes of feeders for systems of electric light supply: (1) because it applies only to bare conductors, of which the cost per mile may be taken as being proportional to the weight of the copper, and therefore to the cross-sectional area; and (2) because it assumes the current to be constant from one year's end to the other, a condition of things which unfortunately has not been realised by electric supply stations. Although Thomson's law, in its usual form, is not directly applicable to existing conditions, the spirit of it should never be deliberately neglected. All that we have to attend to is this—to see that annual cost of the energy wasted in a mile of the feeder, added to the annual allowance (per mile) for depreciation and interest on first cost, shall be a minimum. With regard to the question of varying current, this is easily dealt with. The energy lost in a given cable depends upon the square of the current and the time during which the current is flowing. If a cable conveys a current, C, only 12 hours out of the 24 hours, then the energy wasted per day is only half what it would have been had the current been flowing continuously, and the watt-hours may be expressed as $12 \times C^2 \times R$, or as $24 \times \frac{1}{2} C^2 \times R$, and it is evident that in working out the energy lost per annum in the cable, we have to multiply the resistance, not by the square of the maximum current which the cable will carry, but by the mean value of the squares of the current during the year.

From measurements taken on actual load diagrams it would appear that, in the case of electric light supply stations having a small all-day load, the full load or maximum current is from two to three times as great as the mean square value of the current taken for the whole year; this proportion depending upon whether the capacity of the feeder is appreciable or not, and also upon the nature of the districts supplied. It is evident that this multiplier can easily be worked out from a few typical load diagrams. The following example and the Diagram No. 2 will make it clear how the proper size of cable may be worked out in actual practice. And first it should be understood that it is the cost of the cable only on which the percentage for interest and depreciation should be taken, because the cost of trenching and laying, or drawing into pipes or culverts will be practically constant, and unaffected by the exact cross-section of the copper in the cable. Let us suppose that 10 per cent. is to be allowed for depreciation and interest on capital spent; then, in the Diagram No. 2, where the horizontal distances represent resistance in ohms, and the vertical distances represent money, plot the curve A, which gives the relation between 10 per cent. of the cost per mile of the cable (taken from the maker's price-list) and its resistance in ohms per mile (go and return)—this curve, which has been plotted from actual prices for concentric cables by a certain firm of well-known manufacturers, is not a rectangular hyperbola, as it would be if Thomson's law were to hold good. The dotted curve is a true hyperbola or the curve which makes the cost universally proportional to the resistance of the cable, and inspection of these two curves will show how the cost of the (insulated) cable is proportionately greater for the smaller sizes. Now calculate the cost of the $C^2 R$ losses per mile of cable for any particular value of the resistance, and draw the straight line, O B, which will give us this cost for any other resistance of cable. In this diagram the losses have been calculated on the assumption that the current is 26 amperes, and that the cost of production is 1½d. per unit. It is evident that this must be taken on the low side, as during the lifetime of the cables the works cost per unit may be expected to be reduced. By adding the ordinates of the curves A and B, the curve C is obtained, whose minimum value corresponds with a resistance per mile of ·78 ohm. The nearest cable to this (on the small side) is $^{19}/_{14}$, and this, if the cost of production of electrical energy and the probable current have been estimated correctly, is the proper size of cable to use, whatever may be its length or the voltage required at the feeding point. Assuming the maximum value of the current to be three times the square root of the mean square value, and the length of the feeder to be one mile, the "drop" at full load would be $78 \times \cdot 91 = 71$ volts.

Capacity.—The effect of capacity in a system of concentric mains is to increase the current entering the cable at the alternator end, although the current leaving the cable at the far end will, of course, depend only on the pressure and lamp load at that end. In the long concentric feeders the capacity current should therefore be taken into account, especially as its effect in increasing the total current is more marked at light load than at full load. It is easily calculated with sufficient accuracy by the formula $C = 2 \pi n K V$,

where K = the capacity in farads;
n = the frequency in periods per second;
V = the mean voltage.

It must be remembered that this current is not in phase with the main current, but quarter period in advance of the impressed

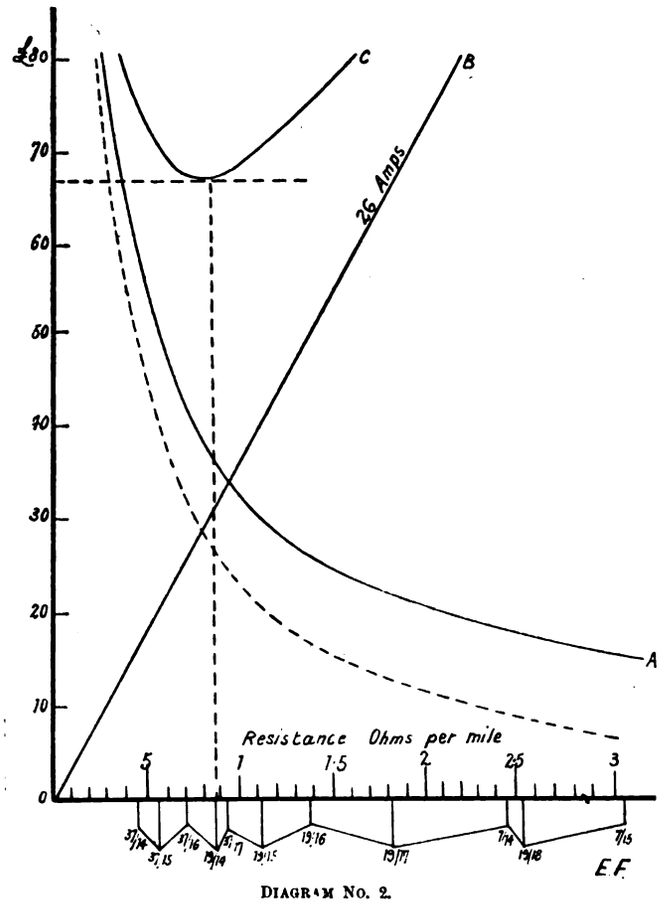

DIAGRAM No. 2.

volts. Hence, if C = 10 amperes, this will be the current indicated by the feeder ammeter on open circuit. At full load, with 60 amperes taken out at the far end, the current read on station ammeter will be the square root of $60^2 + 10^2$, or about 61 amperes. The following capacities of concentric cables have been kindly furnished us by the makers, and may be found useful in estimating the probable value of the capacity current in a given system of mains. Capacities per mile (inner to outer) of $^{19}/_{18}$ concentric cables: British Insulated Wire Company (paper), ·31 microfarad; Glover and Co. (vulcanised rubber), ·615 microfarad; ditto (diatrine), ·315 microfarad.

Drop on Feeders.—Having fixed the cross-section of the feeders and calculated the full-load "drop," it will generally be found that the latter is considerable on the long feeders and inappreciable on the short. Some methods of dealing with this difficulty must therefore be adopted which will allow of each feeder being independently regulated, as, if we raise the pressure of the 'bus bars to compensate for the drop on the long or heavily-loaded feeders, we shall be at the same time increasing the pressure at the feeding points which are nearer the generating station or at those which are more lightly loaded. There are three methods of effecting the desired result, all equally efficient in respect to regulation, but differing widely in their efficiency in respect to economy: (1) raise pressure of generators until 'bus-bar pressure equals that required for the feeder with the largest drop, and switch more

Digitized by Google

or less resistance into all the other feeders to absorb the consequent excess of pressure above that required; (2) same as above, but use variable choking coils instead of resistances; (3) adjust pressure of generators until 'bus-bar pressure equals that required for the feeder with the least drop, and by means of a special induction apparatus add pressure as required to the remaining feeders.

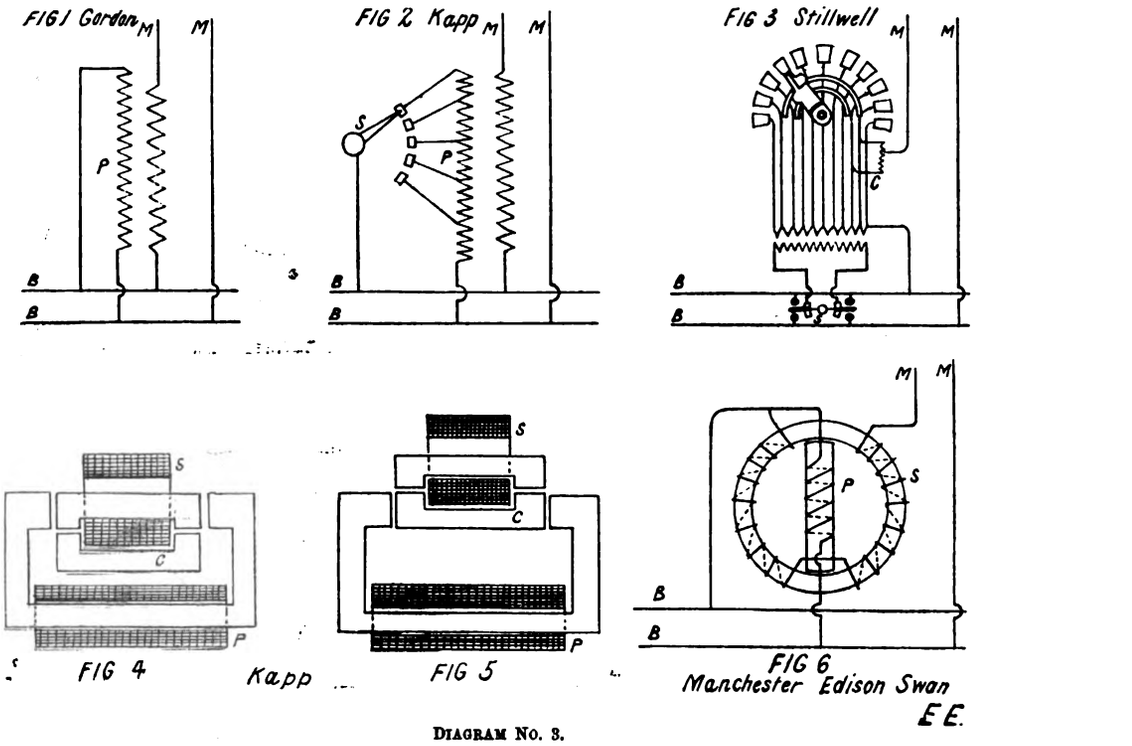

DIAGRAM NO. 3.

Very few words will be required to show the great economical advantage of the third method over the two others. In the first plan the resistances dissipate energy which has cost fuel to produce, and so rob the station of a percentage of its output at the time of maximum load—a serious disadvantage in itself. The second plan is much more economical than the first. But choking coils are not like transformers, the induction and consequent loss in the iron being very much higher on account of the E.M.F. of self-induction being quarter period out of phase with the main current. For a 10 per cent. reduction of pressure the amount of the induced volts will be over four times the volts deducted. But apart from this it will be readily seen that the generation of the E.M.F. by the dynamo and its subsequent destruction by the choking coils cannot be an economical arrangement, accompanied as it must be by the losses of a double operation. The third plan is free from the above objections. The volts required to compensate for drop are added when and where required, and the generators, being worked at a low pressure, work more economically. Without analysing the question, common sense tells us that such a plan is better engineering. When we want to light a part of a building we do not think it right to switch on all the lamps and screen the light from those parts not needing illumination, and there is no more reason for regulating feeders upon a similar principle. The use of a regulating transformer for this purpose was first brought under our notice by Mr. J. H. Rider, who designed and specified such an arrangement for the Bolton Corporation electricity supply station. The principle was not, however, new, and it may be of some interest to trace its development. As far as as we have been able to ascertain, the late Mr. J. E. H. Gordon was the first to make use of the idea of augmenting the E.M.F. of a circuit by connecting in series with it the secondary coil of a shunt transformer. In Diagram No. 3 this plan is illustrated. He termed the apparatus a "hitcher-up." Fig. 2 on the same diagram shows a feeder regulator designed by Mr. Gisbert Kapp; this apparatus is the same as Gordon's, but is provided with a means of varying the augmentation. A segment switch is arranged to cut out the primary coils as desired; as the coils are cut out the E.M.F. generated in the secondary is, of course, increased. Fig. 3 (Diagram 3) shows the principle of an apparatus designed by Stillwell, in America, and manufactured by the Westinghouse Company. This design is similar to Kapp's, and was indeed also suggested by him, the only difference being that instead of primary coils being cut out secondary coils are switched in. Figs 4 and 5 at the bottom of the diagram illustrate another design of Mr. Kapp's, which was intended to get over the difficulties of a high-tension segment switch, with its necessary devices to avoid short-circuiting a coil when being moved from one segment to another, and also to get over the objection of the additions to the voltage taking place in jumps, the necessary result of using a segment switch. The principle of its action is entirely different to the others, the variation in effect being obtained by a movement of the iron core. Fig. 4 shows the apparatus in the position of maximum effect, the magnetism created by the primary coil cutting the secondary coil. In

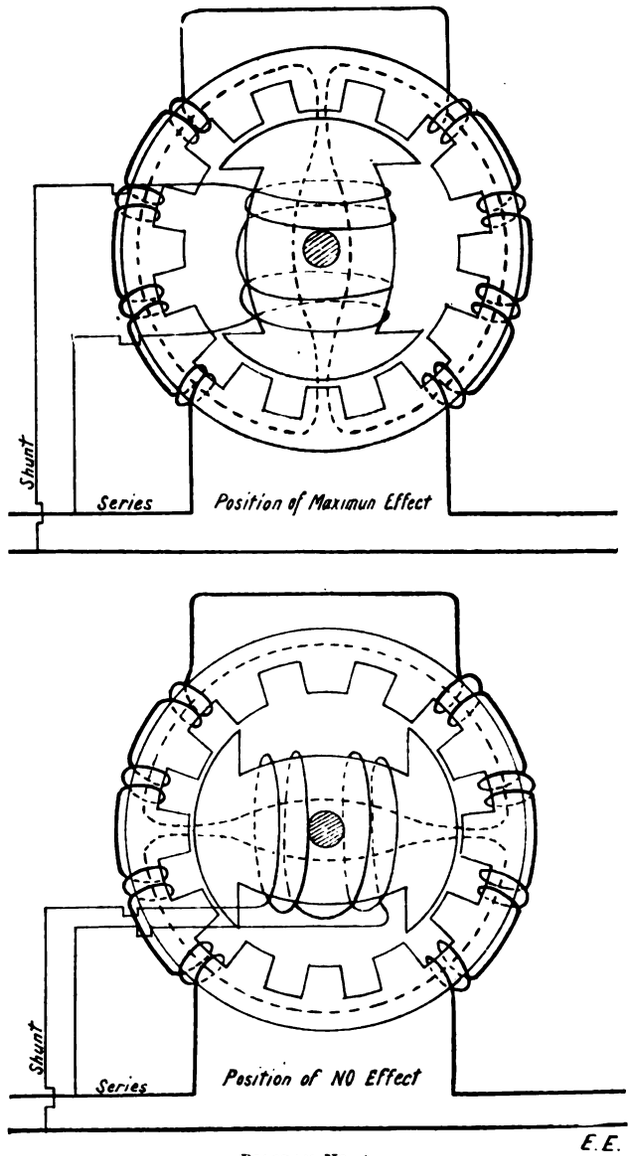

DIAGRAM NO. 4.

Digitized by Google

Fig. 5 the core and secondary coil are removed to the position of no effect, the magnetic lines flowing along the core, C, outside the secondary winding instead of through it. We are not aware that this regulator was ever made. It is perhaps scarcely fair to criticise it, but it is apparent that in the position shown in Fig. 5, the self-induction of the secondary would result in a serious loss of pressure in the feeder, and in the position shown in Fig. 5 the magnetic leakage would be appalling.

Fig. 6 (Diagram No. 3 and Diagram No. 4) illustrates the regulating transformer manufactured by the Manchester Edison-Swan Company, Limited, as first made for the Bolton Corporation. In this design the primary coil is wound upon a shuttle-shaped core and the secondary winding upon a ring-shaped core. Between the positions of maximum effect and no effect, the primary coil, with its core, rotates through an angle of 90deg. The action is as follows: In the position of maximum effect the shuttle occupies a vertical position, and the magnetic flux cuts the secondary coil, which is wound in two sections, one on each side of the ring, and generates the full volts required. In the position of no effect the shuttle is horizontal, and the magnetism cuts half the secondary turns in a positive sense and half in a negative sense, the resultant effect being of course nil. Between these two positions any gradation of augmentation can be obtained. It is evident that if the shuttle be rotated beyond the position of no effect (if the transformer is being used as a feeder regulator), volts will be subtracted from instead of added to the feeder volts. The points to which special attention were paid in the design of this apparatus were the constancy of magnetic flux in all positions, the reduction of the iron path to the shortest possible length to avoid iron loss, and the obtaining of a mechanical and compact apparatus which would lend itself to easy and safe manipulation by the switchboard attendant.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS.

COMPANIES' MEETINGS AND REPORTS.

DIRECT SPANISH TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Tuesday at Winchester House, E.C., Mr. Edmund Etlinger presiding.

The **Chairman**, in moving the adoption of the report, first spoke with regret of the serious illness of the chairman of the

Digitized by Google

Company, Sir John Pender, and expressed a sincere hope that he might soon be restored to health. During the past year they had earned sufficient money, after deducting not only the ordinary expenses of working the traffic, but some rather expensive extraordinary expenses, to enable the Board to recommend the big dividend of 10 per cent. for the year on the preference and 4 per cent. on the ordinary shares. The receipts had exceeded those of the previous year by £4,571; but the insurrection in Cuba had brought a vast amount of traffic over their wires. The ordinary expenses for working the traffic had been £238 more but there had been exceptional expenses amounting to £1,953, of which, however, £1,660 was attributable to the damage done to the Bilbao cable in 1894. In November of that year a steamer fouled their cable outside Bilbao. They brought an action against the owner of the vessel, but they failed. Still, one good thing had arisen out of the action so far as the future of all submarine telegraph companies was concerned. It came out during the trial that the ship which fouled their cable got its anchor entangled with two cables, one of them probably an abandoned cable of the Spanish Government. Both cables were dragged up to the surface, but the lighter of the two got disengaged from the anchor and disappeared, while with the other, which the Company claimed as theirs, nothing could be done, so it was severed. The important part of the judgment was in the following passage: 'If we were satisfied that the cable belonging to the plaintiffs had been cut, we should be of opinion that the captain had done that which he was not entitled to do, and that the defendants were responsible for the injury so caused, but we are not satisfied from the evidence that the cable of the plaintiffs was cut." That, he assumed, was the whole point on which they lost their case. He supposed it would be possible for hundreds of ships to anchor and never drag up two cables again, and he assumed that if in the future a ship fouled a cable, and those in charge of the vessel deliberately severed the line, the owner of the ship would be liable. A short time since a small ship fouled the Company's cable outside Falmouth. The captain on finding what had happened slipped all his gear and ran into port. He afterwards asked the Company to pay the damages, which they did, as he had taken the right course.

Mr. John D. Pender seconded the motion.

In reply to **Mr. Cochrane**, the **Chairman** said the returns for January and February had been extremely favourable, but with regard to Cuba, when there was an insurrection in a country trade must necessarily suffer. On the other hand it did not follow that the full force of that would be felt on this side, because the Spanish traded very largely with the United States, where a large proportion of these bad times would be experienced. He should have stated that they had placed £5,000 to the reserve, thus bringing it up to £28,000.

The report was then adopted.

At an extraordinary meeting subsequently held. Clauses 90 and 91 of the articles of association concerning the directorate was amended, the director to retire in the future being the one who has been longest in office.

BELL'S ASBESTOS COMPANY, LIMITED.

The eighth ordinary general meeting of this Company was held last week at the Cannon-street Hotel, E.C., Mr. Henry Heywood presiding.

The **Chairman**, in moving the adoption of the report, said that at the date of their last meeting their business at Southwark-street was increasing month by month and the demand for crude asbestos at the mines was good. Everything, in fact, pointed at the time to a satisfactory result at the end of their financial year. It was, therefore, with the greatest disappointment that the directors had to present a statement showing so great a diminution in the profit on the past year's trading. For some reason, the Johns Manufacturing Company, of New York, had refused to take deliveries of crude material which they had purchased of this Company, but he could not say for what reason. They would naturally understand that if, after making contracts extending over a considerable period of time and having mined and prepared the material, deliveries were not accepted serious loss must result. The managing director had proceeded to New York for the purpose of making some arrangement but his visit ended in failure, and there was no alternative for them but to take legal proceedings against the Johns Manufacturing Company. The business done by the Company during the year in Southwark-street had been, on the whole, perfectly satisfactory, and had increased during the year. Competition had been very severe, however, and prices had not been maintained.

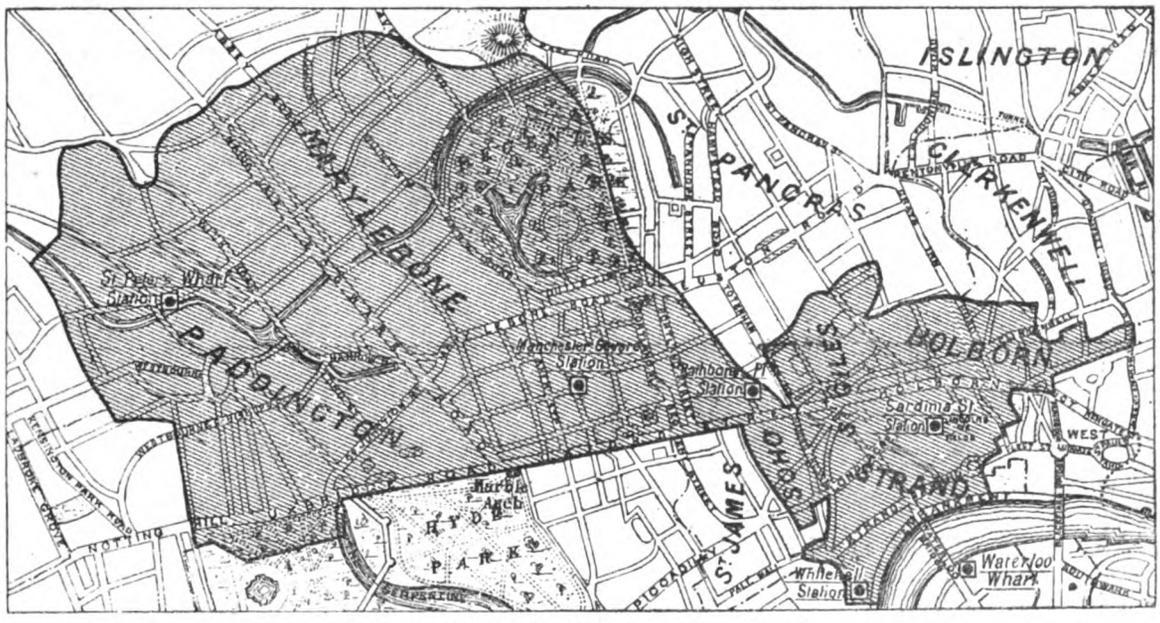
Mr. A. J. Burnett seconded the motion.

In reply to questions, the **Chairman** repeated that he did not know the reason why the Johns Manufacturing Company had refused to take deliveries. They stated that the Company were rather late in tendering the materials which had been bought, but this was denied.

The motion was adopted, and a dividend at the rate of 3 per cent. per annum was declared.

METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

Report of directors (with abstract of accounts) to be presented to the shareholders at the ordinary general meeting to be held at Winchester House, Old Broad-street, E.C., on Tuesday, March 31, at 12 noon.



Metropolitan Electric Supply Company.—Area of Supply.

The capital expenditure, which at the end of 1894 amounted to £628,931. 7s. 1d., has now reached a total of £675,484. 3s., having increased during the year by the sum of £46,552. 15s. 11d. As in the year 1894, this increase is caused by the development of the Company's operations, and principally consists of the cost of mains, transformers, and meters for the purpose of supplying consumers. In order to meet the growing demand for current it has been found necessary to push forward with extensions both of building and plant at the Sardinia-street and Amberley-road stations, and when these extensions are fully equipped they will provide for a considerable increase of business. A serious fire occurred at the Sardinia-street station on June 24, 1895, resulting in the complete destruction of the dynamo-room and contents, and damage to the station generally, but, owing to the system of trunk mains and to the assistance promptly rendered by the City of London and the London Electric Supply Companies, the inconvenience to the Company's customers was reduced to a minimum. The directors anticipate that the amounts received from the insurance companies will be sufficient to provide for the reinstatement of the buildings and plant, but as the permanent arrangements are not completed the accounts relating to the fire cannot yet be closed, and they appear in the balance-sheet for the present as an item in suspense. The gross revenue for the year amounted to £106,447. 8s. 9d., against £85,345. 18s. 7d. in 1894, being an increase of £21,101. 10s. 2d., as compared with the increase of £16,150 14s. 3d. in 1894, which the directors consider satisfactory. The balance to the credit of the revenue account, before providing for depreciation, is £39,154. 0s. 7d. The directors have set aside £12,000 as an addition to the depreciation fund, carrying to the credit of the net revenue account (No. V.) the sum of £27,154. 0s. 7d., which, with the balance brought forward from last account and other receipts, makes a total of £28,961. 0s. 8d. After deducting debenture interest and other charges, there appears a balance of £22,082. 4s. 4d., of which the directors have appropriated a further sum of

Digitized by Google

£1,000 in reduction of the preliminary expenses account, which is now diminished to £1,052. 10s. 4d. An interim dividend of 3s. per share on the ordinary share capital was paid on November 13, 1895, amounting to £7,485, and the directors recommend that a further dividend of 5s. per share be now paid, making a total dividend of 8s. per share for the year, or 4 per cent. on the capital. This will absorb a further sum of £12,475 and leave a balance of £1,122. 4s. 4d. to be carried forward to the next account. The number of 8-c.p. lamps supplied by the Company increased during the year 1895 from 209,000 to 260,000. The present number of lamps connected is 272,000, and the applications show no signs of decrease. A report from the Company's chief engineer is appended, showing that the satisfactory condition of the stations, machinery, and plant has been maintained. In accordance with the articles of association, the following directors—viz., Sir John Pender, G.C.M.G., M.P., Admiral of the Fleet Lord John Hay, G.C.B., and Joseph Charles Parkinson, Esq.—retire from the Board, and are eligible for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and are eligible for re-election.

Report of Chief Engineer.—I have pleasure in certifying that the Company's stations, machinery, and plant are being maintained in an efficient condition and have worked satisfactorily up to the present date.—FRANK BAILEY.

REVENUE ACCOUNT FOR YEAR DEC. 31, 1895.

Dr.		£ s. d.
Generation of Electricity.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: the Right Hon. Lord Rathmore, LL.D. (chairman); J. B. Braithwaite, jun. (deputy-chairman); W. C. Braithwaite; Emile Garcke; Frederick W. Reynolds; Aymor H. Sanderson; Francis E Savory; R. Percy Sellon; B. H. van Tromp. Engineer and manager, A. J. Lawson, M.I.E.E. Secretary, H. Renwick.

Report of the directors (with abstract of accounts) to be presented to the shareholders at the second ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., at 2 p.m. on Monday, April 13, 1896:

The capital expended during the year on the London stations amounted to £92,151. 10s. 9d.; the investments in shares and debentures of, and the sum advanced to, associated companies amounted to £73,396. 5s. 10d.—total, £165,547. 16s. 7d. This expenditure has been met by instalments falling due on ordinary shares and by the issue of 10,000 6 per cent. preference shares at par, mentioned in last year's report, which were applied for several times over, and now stand at a substantial premium. The balance to credit of revenue account for the past year, after payment of proportion of rents, rates, taxes, and general establishment charges, amounts to £2,714. 7s. 9d., to which must be added £332. 5s. 10d., brought forward from 1894 account, making a total of £3,046. 13s. 7d. Out of this sum an interim dividend for the half-year ending June 30 1895, at the rate of 6 per cent. per annum on the preference shares, was paid on July 15 last, and the directors recommend that a further dividend to December 31, 1895, at the same rate be paid upon the preference capital. This will leave a balance of £1,208. 19s. 1d. to be carried forward to next year's account. In the St. Luke and Clerkenwell districts the cables required for the compulsory streets have been drawn in and the transformer sub-stations have been constructed, but, owing to a strike of contractor's workmen, much delay has taken place in the completion of the generating station. Applications have nevertheless been received for the equivalent of 7,000 8-c.p. lamps, of which 5,700 are now connected to the Company's mains, and the directors anticipate that there will be a sufficient number of lamps applied for by the time the station is completed to ensure a profit being earned from the commencement of working the plant. In the Wandsworth district the Company's operations have been materially retarded, owing to objections having been taken by the local authority to the construction of transformer boxes in the streets. All questions have now, however, been satisfactorily arranged, and the generating station on the Wandle will soon be completed. The conduits for cables have been laid throughout the district, cables are being drawn in, and it is expected that about September next current will be available, along the route of the Company's mains, for all consumers who may then have applied for connection. In the St. Olave district, to which reference was made in last year's report, the provisional order was granted by the Board of Trade; owing, however, to the dissolution of Parliament, it was not confirmed last session. It will come up for confirmation in the present session. The Company has also applied to the Board of Trade for a provisional order for other areas in South London, and has received the consent of the Camberwell Vestry to the granting of an order for the district within its jurisdiction. The Company will be in a position to supply the parishes of St. Olave, St. George-the-Martyr, and Camberwell from one generating station. During the past year the Bournemouth Company's station has been completely remodelled and enlarged, and additional plant and mains have been laid. That station has now plant capacity for 27,500 8-c.p. lamps, and the equivalent of 21,000 8-c.p. lamps connected. The work of laying mains and equipping the Dover Company's station was completed last year, and an uninterrupted supply of current has been given since April, 1895. Referring to the plant supplied by the Brush Electrical Engineering Company, the Dover Company's directors in their report state: "In October last,

Digitized by Google

exhaustive tests were made by Profs. A. B. W. Kennedy and Silvanus Thompson of the whole of the machinery in the station, with gratifying results, the efficiency of the plant being found to be very satisfactory." The professors in concluding a lengthy report state: "On the whole matter of the working of the boilers, and of the running of the plant in the station, it gives us pleasure to say generally, in conclusion, that as to output, efficiency, and economy, as well as in respect to general construction, the results are very satisfactory, and are substantially in accordance with the conditions of the specifications." The contract for street-lighting has been increased, and the equivalent of 4,557 8-c.p. lamps has already been connected to the Company's mains. The Richmond station, in which this Company obtained the controlling interest in April, 1895, has yielded, with an equivalent of 5,486 8-c.p. lamps connected at December 31 last (being an increase of 1,746 8 c.p lights within the year), a profit of £230. 2s. 1d. upon the 12 months' running, as against a loss of £978. 19s. 8d. in the previous year. Additional mains have lately been laid in order to reach new consumers, and further extensions are now under consideration. Mr. A. N. Denny, owing to unavoidable absence from England, has resigned his seat at the Board, and the directors have elected Mr Emile Garcke to fill the vacancy thus created. The retiring directors are Mr. J. B. Braithwaite, jun, and Mr. A. H. Sanderson, who are eligible for re-election. The auditor, Mr. R. H. Marsh, also retires, and is eligible for re-election.

SCARBOROUGH ELECTRIC SUPPLY COMPANY, LIMITED.

Directors: G. Alderson-Smith, Esq. (chairman); John Dale, Esq.; John Woodall Woodall, Esq.; George Lord Beeforth, Esq; John Bell Simpson, Esq.; the Hon. Charles A. Parsons; Gilbert Wilkinson, Esq.; John Edward Ellis, Esq, M.P.; A. A. Campbell Swinton, Esq. (managing director). Mr. John Hall, secretary. Mr. G. S. Peck, resident engineer.

Report of directors, revenue account, and balance-sheet for the year ended December 31, 1895:

During the past year the Company has continued to make satisfactory progress. New customers to the number of 52, and the equivalent of 2,285 8-c.p. additional lamps, have been connected to the Company's mains, making a total of 235 customers and 12,788 equivalent 8-c.p. lamps connected to the present time. Since the date of the last report 571 yards of additional mains have been laid, making, with what previously existed, a total of 13,263 yards. The capacity of the mains and the number and capacity of the transformers have also been increased. To meet the increased demand, an additional boiler and two additional sets of engines, dynamo, and condenser, one set of 150 h.p. and one of 100 h.p. have been obtained, and are now in satisfactory operation. During the past year electric energy to the amount of 141,101 Board of Trade units has been supplied to customers at a gross revenue, including meter rent, of £3,613. 19s. 5d. Deducting from this the expenses, there remains a balance of £937. 9s. 8½d., which is more than twice the profit made in 1894. Adding the balance of £418. 12s. 3d. carried forward from the previous year, there is a sum of £1,356. 1s. 11½d. available for distribution. The directors recommend that this should be applied (1) in paying a dividend of 2½ per cent., which will absorb £772. 13s.; (2) in writing off the sum of £304. 16s. 0½d. from the preliminary expenses, leaving a balance of £278. 12s. 11d. to be carried forward. Mr. J. E. Ellis and Mr. Gilbert Wilkinson retire by rotation, but are still eligible, and offer themselves for re election as directors. The auditor, Mr. C. E. Bradley, C.A., also offers himself for re election.

The fourth annual meeting of this Company was held at Scarborough last week, Mr. J. W. Woodall presiding.

The **Chairman** in moving the adoption of the report, expressed sincere regret that, owing to a rather serious illness, the chairman of the Company, Mr. G. A. Smith, was unable to be present. Proceeding to refer to the report, the Chairman said that that statement represented the first whole year's working, because during 1894 they had hardly settled down to the work and conditions of supply. The policy pursued by the members of the Board had been, and would be in the future, to give as good a supply as possible to the consumers whilst attempting to carry out such economy as would eventually conduce to the proper working of the concern. Owing, as Mr. Swinton, the managing director, would tell them, to the expense incurred by the great amount of current that was required at a late period of the autumn, their receipts per lamp did not show a very large average. But, on the other hand, the cost of production per unit would compare very favourably indeed with that of other companies which were far better situated for a continual demand. A moderate increase in the winter supply and a further demand would show better results, and there was every reason to hope for such a demand in the future. The result of the working for the year, according to the balance-sheet, would allow a dividend to be paid at the rate of 2½ per cent. on the paid-up capital, after writing off sundry expenses connected with the formation of the Company. The result of the working, after bringing forward £418 12s 3d. from the revenue account of the previous year, showed a balance to the credit of the revenue to the amount of £937. 9s. 8½d., which made a total of £1,356. 1s. 11½d. available for distribution. Of this sum they were reminded by the directors that £304 should be written off from the preliminary expenses, which would leave a sum of £350. There was another item which would also have to be reduced regularly, and that was the provisional order of £525. That would have to be written down, and would have to be provided for in the reserve fund. Then they proposed to pay out of the £1,356, less the £304, £772 less income tax on the shares, and to carry forward an amount of a little more than £278. This would, he thought, be all that they could do that year. They were bound to look forward and provide a year's income for the Company for the future. Then he might say that as certain of their directors were residents in Newcastle, and as the Newcastle shareholders had a very large interest in the concern, it was thought that they should be remunerated and their expenses paid for coming over to Scarborough, because it involved a whole day, and very often it meant their remaining overnight. Therefore a motion would be made for a certain sum to be voted in order to meet the necessary expenses incurred in this way. In conclusion, Mr Woodall said he begged to move the adoption of the report and balance sheet, and that a dividend of 2½ per cent. be declared upon the amount standing to the credit of the shareholders.

Mr. A. A. Campbell Swinton seconded the motion, saying that the progress of the Company, though slow, was very satisfactory. The people in Scarborough consumed a very small amount of electricity per lamp. If they took the consumption and units and divided it by the number of lamps they would only get 11 units per lamp per annum. Coupled with that, they supplied current at a very low rate, much lower, in fact, than was the case in some places, and they only got a little under 5s. 6d. per lamp. This was the lowest amount, he might say, received in the case of any company in Great Britain, and, of course, when they got a very low revenue they could not expect a very large margin of profit. In 1891 there were 6,378 additional lamps. The increase last year had not been anything like that. It was not to be expected, because the previous year was really the first year of working. He thought if they went on adding at the rate of 2,285 lamps per annum they would do very well. They were adding mains at the present moment along Victoria-road, and, of course, all these mains were very expensive, and in taking into account the cost of these mains, wires, and cables, it should also be taken into account that everything had to be done upon a scale that would enable them to deal with a very much larger number of lamps than were actually connected. They did not put any larger cables into the pipes than they really wanted, but the pipes themselves were sufficiently large to take double the number of lamps that they provided at the time. Unless they did this a great deal of unnecessary work would be caused by their having constantly to take up the mains again.

After some conversation, in the course of which **Mr. Sinfield** suggested that there ought to be a higher dividend, the report and balance-sheet were adopted and the retiring directors re-elected.

Mr. L. P. Edwards proposed, and **Mr. F. Bright** seconded, that the sum of £100 be voted for the purpose of remuneration to those directors coming to Scarborough from a distance for the purposes of the business of the Company, and the motion was carried without opposition.

TRAMWAYS ELECTRICAL TRACTION COMPANY, LIMITED.

The report of this Company for the year ended February 29, 1896, states that the directors have entered into negotiations with the French Thomson-Houston Company for the sale of the Company's interest in the Rouen Tramways Company. An agreement was come to, the French Thomson-Houston Company taking over all the liabilities, repaying the cash advances made on account of the Rouen Tramways Company, with interest at 6 per cent., and acquiring for £100,000 the 7,094 ordinary and 48 *jouissance* shares in the Rouen Company owned by this Company, and these sums will be paid over in cash on April 10 next. The net result of the sale is that there is a balance at credit of profit and loss account of £81,215, and it is proposed to pay a dividend of £5 per share on 15,000 ordinary shares of £1. 10s. each (fully paid), leaving a balance to be carried forward of £2,090. The directors propose to wind up the Company, with the view of returning the paid-up capital—viz., £5 per share on the preference and £1. 10s. per share on the ordinary shares.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Derby.—The Corporation want tenders by April 13 for low-tension cables and junction boxes. Particulars will be found in our advertisement columns.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadrath, Prague.

Copenhagen.—Tenders are required for the supply to the Danish State Railways of eight tons of telegraph wire, a quantity of pine wood, 8,000 zincs for telegraph batteries, and 1,800 caps.

Paris.—On April 9 there will be a limited competition at the Hotel de Ville for the supply of eight standards for the electric lighting of the Quai de Jemmapes and the Quai de Valmy.

Elberfeld.—Tenders are wanted by April 20 for the supply of four engines and dynamos and 174 lamps, conductors, etc , for the Prussian State Railways. Address, die Königliche Eisenbahn-Direktion, Elberfeld, Germany.

Vienna.—Tenders are wanted by April 15 for the supply of fastenings and tubes for an extension of the Vienna telephonic system. Particulars can be obtained from the Austrian Administration of Posts and Telegraphs, Section 13, Vienna.

Harrogate.—Tenders are wanted by April 7 for the electric lighting of the Prince of Wales Hotel. The installation is to be for about 400 lights, with engine and dynamo, and also an installation of telephones and electric bells. Particulars can be obtained from Mr. W. Leake, 30, Victoria-buildings, Manchester.

Brunn (Austria).—The Municipality desire offers for the construction and working of a central station for the supply of electric energy for lighting the town, for power, and. if required, for running a tramway. Tenders must be sent before March 31 to the Bürgermeister, Brünn, Austria, from whom particulars can be obtained.

Chiclana de la Frontera (Spain). - Tenders are wanted for the electric lighting of Chiclana de la Frontera, near Cadiz. The number of lamps required is 210 16 c.p , and the estimate is 15,000 pesetas (about £600) a year. The duration of the contract is 15 years, and tenders must be sent to the local authorities before April 6.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and main-

Digitized by Google

tenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, 13, Comeragh-road, West Kensington, W., where applicants can obtain a memorandum explaining the local conditions. The tenders will be opened and considered by the Municipality of Lima, which reserves to itself the right of selecting that which is most approved or rejecting all if it thinks fit.

Shoreditch, E.—The Vestry require tenders for engines, electric generators, switchboards, pumps, steam and water mains, cast-iron work, motor transformers, and accumulators. Specifications, etc, can be obtained of the consulting engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, S W, on payment of £3. 3s, which will be returned on the receipt of a bona fide tender. Tenders, endorsed "Tender for Contract No. 4." to be sent in by 4 p.m. on April 14.

Bedford.—The Electric Light Committee invite tenders for the supply and erection of the following plant: (Section A) one 240-b h.p. double-acting compound enclosed engine, (B) one 150-unit alternator, with stationary armature. Specifications, with terms and conditions of tender and contract, may be obtained at the offices of Mr. T. S Porter, clerk to the Urban Sanitary Authority, Town Hall, Bedford, on payment of a fee of 5s. for each section. Tenders sealed and marked "Electric Lighting, Section A or B," must be delivered to the clerk by April 4.

Bradford.—The Corporation invite tenders for the erection of a building required for the new electricity station at the junction of Valley-road and Lionel-street in the borough. Plans and specifications may be seen and bills of quantities obtained, free of charge, on application to Mr. Thomas Barker, A.M.I.C.E., architect, at his offices, 5, Bond-street, Bradford. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages. Tenders, endorsed "Tender—Electricity Works," to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by April 8.

Chesterton (Cambs).—The Urban District Council are open to receive tenders for the public lighting of the district for seven years. The tenders shall be made in the three following modes—namely, (*a*) lighting the district from August 14 to May 15 (inclusive) in each year; (*b*) lighting the district throughout the whole year commencing May 15 next; (*c*) lighting the district for either of the above periods (1) with ordinary burners, (2) with incandescent burners, if the illuminant with which the tender be made be gas. All cleaning, lighting, and maintenance to be done by the contractors. Tenders to be sent to Mr. James Spearing, clerk, 15, Sydney-street, Cambridge, by March 31.

Cardiff.—The Corporation require tenders for the construction, supply, delivery, and fixing of two boilers of the dry-back marine or water-tube type, each to evaporate about 6,000lb. of water per hour, and one 250 to 300 kilowatt direct-driven steam alternator. Specifications may be obtained on application to Mr. W. Harpur, M.I.C.E, borough engineer, Town Hall, Cardiff. Sealed tenders, addressed to Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, and endorsed "Tender for Electricity Works," must be left at his office by April 6. A fee of £1 1s. will be charged for a copy of the specifications, which fee will be refunded on the return of the specifications, accompanied by a bona fide tender.

Egremont.—The Wallasey Urban District Council require tenders for the following requisites—viz.: (a) steam alternators, switchboard, and accessories; (b) high and low tension concentric cables; (c) transformers. Copies of the specifications may be obtained on application to the engineer, Mr. J H. Crowther, Gas and Water Works, Great Float, near Birkenhead. A charge of £2. 2s. will be made for copy of each specification, to be returned on receipt of a bona fide tender. Sealed tenders, on the form to be provided for the purpose, addressed to the chairman of the Gas and Water Committee, and endorsed "Tender for Steam Alternators, Switchboard, and Accessories," or any other contract, as the case may be, to be delivered at the office of Mr. W. Danger, clerk, Public Offices, Egremont, by 4 p.m. on April 6. Each contractor will be required to enter into a bond with approved sureties for the performance of contract.

Antrim.—The Commissioners for the Control of Lunatic Asylums will receive sealed tenders up to 10 a m. on May 1 for the supply and erection of an electrical installation at County Antrim Lunatic Asylum. The tender should be sent in a sealed envelope, endorsed outside "Tender for Electric Lighting, County Antrim Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and should be accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tenders, and copy of specification, which has been prepared by Mr. J. H. Greenhill, M I E E, will be issued on application to the office of the Board of Control of Lunatic Asylums, Dublin, on deposit of £3, which will be returned to all persons who have sent in bona fide tenders. Plans can be seen at the office of the architect, Mr. John Lanyon, Northern Bank-chambers, Royal-avenue, Belfast.

Manchester.—The Lancashire and Yorkshire Railway Company invite tenders for the supply of the following articles during 12 months ending April 30, 1897: copper rivets, washers, and tubing, signal and telegraph fittings, and signal, telegraph, and electric light wires. Further particulars and forms of tender may be obtained on application at the Stores Department, Osborne-street, Manchester, where parties are requested to call and examine the samples before tendering. The sample-room will be open for this purpose from 23rd inst. to April 2, between 10 a.m. and 4 p.m; Saturday, 10 a.m. to 12 noon. Contractors cannot be allowed to tender to their own patterns, nor can the company's patterns be sent away for inspection, all being sealed and exhibited at Osborne-street. Tenders, properly endorsed, and addressed to the Directors, must be lodged with Mr. C. W. Bayley, secretary, Hunt's Bank, Manchester, by 10 a.m. on April 6. Separate forms of tender will be provided for each contract; parties applying are therefore requested to state the particular contract for which they propose to submit tenders.

RESULTS OF TENDERS.

Durban (Natal).—The Corporation have received the following tenders for the electric lighting plant. Mr. J. Fletcher, borough engineer. Mr. W. H. Radford, C.E, Nottingham, consulting engineer:—

J. G. Statter and Co., 68, Victoria-street, London, S.W.	£17,901	0	0
Wigston Electrical and Engineering Company, Limited, London	17,360	0	0
British Thomson-Houston, Limited, Westminster, S.W.	20,057	3	0
Goddard, Massey, and Warner, Nottingham	23,926	0	0
Brush Electrical Engineering Company, London, E.C.	16,365	0	0
Siemens Bros. and Co., Limited, Woolwich	16,350	0	0
Crompton and Co., Limited, London, E.C.	15,001	16	0
Electric Construction Company, Limited, Wolverhampton (accepted subject to modifications)	15,007	0	0
For cables only.			
Telegraph Manufacturing Company, Limited, Helsby	6,114	0	0
India Rubber, Gutta Percha, and Telegraph Works, Limited, 106, Cannon-street, London, E.C.	5,442	14	0

BUSINESS NOTES.

Rand Central Electric Works, Limited.—Letters in respect of the second call of this Company have been posted.

Manchester.—The City Council have granted an advance in salary of £100 to Mr. C. H. Wordingham, engineer of the electric light department.

Fareham.—At a special meeting of the Urban Council, Mr. Blake, jun., was appointed manager at the electric light works, at a salary of £130 per annum.

Sunderland.—M. F. Tulloch has held the Local Government Board enquiry into the Town Council's application to borrow £16,000 for electric lighting extensions.

A Big Lamp.—It is stated that the Belvedere tower to be erected at the Empire of India and Ceylon Exhibitions will be illuminated by a lighthouse lamp of 4,000,000 c.p.

Worcester.—In consequence of the engineer's report, it has been decided to increase the charge for current for the Sewerage and Water Committees' motors from 1d. to 1½d. per unit.

Western and Brazilian Telegraph Company.—The receipts for the week ending March 20, after deducting 17 per cent. payable to the London Platino-Brazilian Telegraph Company, were £2,694.

Chelsea.—The Vestry have decided to offer no opposition to the Chelsea Electricity Supply Company, Limited, applying to the Board of Trade for a provisional order to light the western portion of the parish.

Notice of Removal.—Messrs. Bergtheil and Young, electrical engineers and contractors, of 13, Walbrook, London, are removing to larger and more commodious premises at 12, Camomile-street, Bishopsgate-street, E.C,

Lambeth.—The Electric Lighting Committee met on Wednesday last, and after a spirited debate they decided by a large majority to recommend the Vestry to accept the offer made by Mr. C. W. Sax for the provisional order.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending March 22 amounted to £1,149, as compared with £943 in the corresponding week of the previous year, being an increase of £206.

Silicon Electric Lamp Syndicate, Limited.—This Company has been registered, with a capital of £8,000 in £1 shares, to carry on the business of electric and other lamp manufacturers and the general business of an electric light company.

Doncaster.—The Doncaster and District Co-operative and Industrial Society's new premises in Station-road, of which the memorial stone has just been laid, will be lighted entirely by electricity. The dynamo-room is in the basement.

Electro-Metallurgical Company, Limited.—This Company has been registered, with a capital of £100 in £1 shares, to acquire, develop, turn to account, and deal with any inventions for the production of chrome or other metals by electrolysis.

Mevagissey (Cornwall).—The electric light company has held its first meeting, Mr. C. M. Grier presiding. Mr. Hedly, the engineer, stated that the street lights were now completed, and he saw nothing to hinder the success of the company.

Electrical Trades Union.—A smoking concert will take place at the Clerkenwell Town Hall, Rosebery-avenue, E.C, under the auspices of the London central branch, on Saturday, March 28, at 8 p.m. The chair will be taken by Bro. G. W. Montague.

Oriental Telephone and Electric Company, Limited.—The directors of this Company have resolved to recommend to the shareholders, subject to final audit of the accounts, a dividend for the year ended December 31 last of 5 per cent., free of income tax.

Digitized by Google

Kharkoff (Russia).—The Municipality has requested French firms doing electric lighting work to forward, addressed Hotel de Ville, Kharkoff, prices and particulars of machinery, including engines and dynamos, as well as lamps, conductors, and fittings.

Electrical Installation Rules.—We have received from the Liverpool and London and Globe Insurance Company an advance copy of the 1896 edition of "Electrical Installation Rules," installations in conformity with which will be allowed by the company at current rates.

Electricity in the Colliery.—Electricity has been practically applied in the Marles colliery in the Pas-de-Calais, where electric locomotives are now in use. These weigh three tons each, and draw three cars, holding each 15 tons of coal, at the rate of 10 miles an hour. They replace 30 horses.

Rathmines (Dublin).—A special meeting of the Commissioners has been held to consider the question of electric tramway extension in the township. Resolutions were passed disapproving of the orders applied for by the Dublin United Tramways Company and the Rathmines, Dundrum, and Blackrock Tramways Company.

Islington.—At the Vestry meeting, the clerk said the Electric Lighting Committee had entered into arrangements with the County Fire Office for increasing very considerably the insurance of the electric light station. They asked the Vestry to refer to the Finance Committee for payment a sum of £171. 8s. 3d. This was agreed to.

Anglo-American Telegraph Company.—The directors of the Anglo-American Telegraph Company, Limited, have resolved, after placing £6,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ending March 31 of 12s. per cent. on the ordinary stock and 24s. per cent. on the preferred stock, less tax.

City and South London Railway.—The returns for the week ended March 22 were £952, compared with £893 for the corresponding period of last year, being an increase of £59. The total receipts for the half-year terminating as above were £11 738, compared with £11,716 in the same period of the preceding year, being an increase of £22.

New Swindon.—At a meeting of the Urban Council the Electric Light Committee recommended that Mr. J. G. Aldridge, electrical engineer, be asked to attend and explain to the committee his former report upon the question of providing electric light in the town. The recommendation was adopted, and the name of Mr. Longland added to the committee in the place of Mr. D. E. Marsh, who has left the town.

London Electro-Plating and Refining Company, Limited.—This Company has been registered, with a capital of £1,000 in £1 shares, to acquire and carry on the business of electroplaters, electrotypers, enamellers, etc., carried on by A. V. Pittar and A. Soden at St. John's-passage, Clerkenwell, as the London Electro-Plating and Refining Company.

Bradford.—Some details have been issued showing the extent to which it is proposed to carry the electric lighting system when the new station has been laid down. The area at present to be covered by the main supply wires will include Manningham and Girlington and Lidget Green on one side, and on the other side Horton, Bowling, and Undercliffe.

Eastern Telegraph Company.—The Company announce the payment on April 14 next of interest of 3s. per share, less income tax, being at the rate of 6 per cent per annum on the preference shares of the Company for the quarter ending March 31, and the usual interim dividend of 2s. 6d. per share on ordinary shares in respect of profits for the quarter ended December 31 last.

Paddington.—A letter was read from the Board of Trade forwarding copy of a letter which they had addressed to the undertakers under the Paddington electric lighting order, with regulations for securing the safety of the public and for ensuing a proper and sufficient supply of electrical energy. The communication was sent to the Electric Lighting Committee of the Vestry.

Institution of Engineers and Shipbuilders.—At the sixth general meeting of the Institution of Engineers and Shipbuilders in Scotland, a discussion took place on Mr. John Inglis's paper on "Rates of Speed and Rates of Freight," and a new paper was contributed by Mr. J. G. Stewart, B.Sc., on "The Manufacture of Welded Iron and Steel Pipes." Mr. William Beardmore contributed a paper on "Nickel Steel."

Paisley.—It has been decided by the Town Council in committee to acquire the necessary plant for providing electric light within a radius of half a mile from the old prison buildings in the centre of the town, where it is proposed to place the workings. This means that all the public buildings will be able to adopt the electric light, and it is expected that most of the principal shopkeepers will also take advantage of it.

Swadlincote.—At the meeting of the Urban Council the Highways, Buildings, and Sewerage Committee reported that Mrs. Woodward has applied for permission to lay an electric cable under the road from her works through Coppice Side to boundary of the district at the Girder Bridge. The matter had been adjourned for further particulars. In the estimate for the next six months £100 is included for electric lighting at Stanton.

Dover.—Mr A. G. Grossmann has finished the installation of the electric light in his studio, which includes a new triple-arc portable lamp, which he has invented specially for taking photographs at night. The lamp is movable on castors, and is attached to a flexible tube which carries the current from the main. The special arrangement, the patent of which is protected by provisional license, adjusts the carbon points by a spring.

The Telephone in Royal Residences.—Telephonic communication has recently been established between Marlborough House and the general London system, and also between Buckingham Palace and other parts of the Metropolis. In the case of Buckingham Palace, communication with Windsor is now in existence, and members of the Royal household in London and at the Castle respectively can converse with the greatest ease.

Torquay.—The gas company will probably again reduce the price of gas, as a counter-move to the proposal to introduce electric light. "As one much interested in the town," the chairman of the company "trusts the authorities will pause and consider very seriously before embarking further on such a heavy burden to the already heavy debt with such a doubtful return, and with the knowledge, it would seem, that public opinion is against it."

County of London and Brush Provincial Electric Lighting Company.—The directors have decided to recommend payment of a dividend for the six months ended December 31 last at the rate of 6 per cent. per annum from the due dates of payment, less income tax, on the preference shares of the Company, subject to confirmation at the general meeting to be held on April 13. The transfer books and register of members will be closed from April 1 to April 13 inclusive.

Brighton.—During the past week representatives from the Croydon and Ripon Corporations and from the Mile End Vestry have been inspecting the system of street-lighting which has been adopted here, and looking over the generating station, where the new works and extensions are making good progress. It is stated that 38 members of the Association of Municipal Electrical Engineers have definitely arranged to visit Brighton shortly on a similar errand.

Montreal (Canada).—The Lachine Rapids Hydraulic and Land Company, Limited, of Montreal, Canada, have placed an order with Mr. Frederic Nell, of 97, Queen Victoria-street, E.C., for 66 54in.-cylinder gate "Victor" turbines together with all the gearing, shafting, etc., for transmitting the power to the electric generators. The power will be transmitted electrically into the city for street railway and lighting purposes. This is about the largest contract for turbines ever placed.

Leeds.—The first section of the Lamp Committee of the City Council has made a tour of the Mill Hill, West, North-West, and Headingly Wards, and decided to recommend the General Committee to sanction the erection of 16 additional lamps at various points in the districts indicated, chiefly in the courts and alleys. It transpired that no less than 600 new lamps have been erected in the city during the last 12 months, and that Leeds is now illuminated by no fewer than 11,000 public lamps.

Holywood.—A meeting of the inhabitants of the district has been held to consider the feasibility of constructing an electric tramway from Belmont to Holywood along the old Knocknagoney road. Mr. Ryan, M.I.C.E., said the line could be worked by electric traction for about 4d. per car mile, while horse traction costs about 8d. per car mile. Mr. Nance had promised every facility for connecting with the Belfast tramway. A resolution was passed heartily approving the scheme. The overhead system seems to be most in favour.

Blackpool.—It has been suggested that as three-fourths of the electric lighting plant is now lying idle for 20 hours out of each 24, some use should be made of the plant in the way of providing current for the tramway service. Mr. Ferranti has undertaken to enquire if some arrangement of accumulating and converting from high to low pressure could not be devised, so that the machinery not required for electric lighting purposes in the daytime could not only run the tramway system, but store sufficient current as would be necessary to work the cars at night.

Bolton.—At a meeting of the Gas and Electricity Committee the electrical engineer was requested to furnish an estimate of the cost of laying electric mains in Bowker's-row, and a list of the probable consumers. It was reported that in the electricity department the amount received for the month was £628, as against £258 in the corresponding month last year, making a total for the past 12 months of £2,583. There were now 115 connected consumers with an equivalent of 9,378 lamps of 8 c.p., and six consumers nearly ready for connection, making an additional 360 8-c p. lamps.

The London Commissioners of Sewers.—Notice has been given by the Commissioners that they have appointed an electrical inspector, and have provided a well-equipped laboratory to enable him to carry out the duties required under the City of London electric lighting orders. Persons wishing to have their electricity meters tested, or desiring to know the pressure of the electric supply, or otherwise requiring the services of the electrical inspector, as prescribed by the above-mentioned orders, should apply to that officer at the electrical laboratory of the Commissioners in the Wool Exchange, Basinghall-street, E.C.

Llandrindod Wells.—At the meeting of the Urban Council Mr. Vaughan Vaughan, solicitor, Builth, representing Mr. Edward Davies, the electric light contractor, waited upon the Council and stated that Mr. Davies was very anxious to proceed with the work as quickly as possible, so as to get the electric light installed at the earliest possible moment. There would, however, be some details to go into, for which the clerk of the Council or a sub-committee would have to meet Mr. Davies. It was eventually agreed that the clerk should write to Mr. Davies and request him to fix a date for an interview for the discussion of details

Digitized by Google

Telegraphic Communication Along the Coasts —At the annual meeting of the Royal National Lifeboat Fund, the Duke of York, who presided, made special reference to the electrical communication on the coast, and said that in the past year the system had been largely increased, and had already shown to all of what great use and importance it was. The Duke of Norfolk stated that it was the desire of the department he represented to do everything possible to extend that system. The statement that £40 000 was to be expended in the coming financial year to perfect these arrangements would, he felt sure, meet with general approval.

Kingston-on-Thames.—At a meeting of the Town Council Councillor Collings, in moving that a cheque for £100 be drawn in favour of Mr. A. H. Preece, the electrical consulting engineer, said the engagement with Mr. Preece would terminate as soon as the capital outlay to which the Corporation was now pledged in respect of the electric light was completed. Mr. Preece's services had been most useful to the Corporation, not the least valuable part of his work being his influence with Messrs Siemens, in getting them to make and lay an entirely new arc lighting cable free of cost to the Corporation. The cheque was ordered to be drawn.

Canterbury.—Mr. Robert Hammond, the electrical engineer consulted by the Town Council on the subject of an installation in the city, has attended a whole house committee meeting. Mr. Hammond's report was strongly in favour of the adoption of the undertaking by the Town Council. We learn that the majority of the members of the Council were favourably impressed with the scheme, and there is every prospect that it will be carried into effect. No definite expression of opinion has been recorded, but the Lighting Committee were directed to bring up recommendations on the subject in order that the matter may come before the Council in regular form at a future date.

Electric Tricycles.—When the present statutory restrictions in connection with self propelled vehicles are removed there will probably arise a demand for an accumulator suitable for use as a source of power for driving a tricycle. In view of this, the Epstein Company have been turning their attention to the subject and have produced cells which will give 10 to 12 watt-hours per pound weight. Assuming that about a quarter of a horse-power is required, this gives a weight of from 15lb. to 19lb. per hour run. The main point of the new cells, however, is stated to be not so much their weight as the very wide limits within which the rate of discharge can be varied. It remains to devise a suitable motor.

Appointments Vacant.—The Corporation of Morley require the services of a competent man to take the entire charge of the electric light installation of the town hall, including the engine, boiler, dynamo, and lamps throughout the building Applications, stating previous experience, age, and salary required, to be received by Mr. R Borrough Hopkins, town clerk Town Hall, Morley, not later than noon on 30th inst. All applications to be endorsed "Electric Lighting."—The Lighting and Electrical Committee of the Cardiff Corporation have decided to advertise for three competent engine-drivers, resident in the town, at a salary of 34s. per week; and also for a qualified fitter at 42s per week.

London Improvements.—Mr. H. T. Steward, Home Office inspector, has concluded his enquiry into the scheme prepared by the London County Council under the Housing of the Working Classes Act for clearing a large area in Clare Market declared insanitary by the medical officer of health. Mr. Wolton, engineer to the Metropolitan Electric Supply Company, was examined with regard to the effect that the carrying out of the scheme would have upon the mains of the company in the district. He stated that there would be a great loss of energy if the mains were altered or transferred, in addition to an enormous cost being entailed. There might also be considerable danger to life involved in any change.

London.—The Highways Committee of the London County Council have received an application from the National Telephone Company for the use of 144 square inches of sectional space in the Commercial-road subway, between the junction of Commercial and Whitechapel roads and the end of the subway. The committee recommend that the request be acceded to upon condition that all work in or about the subway in connection with the placing of the company's wires therein shall be carried out under the supervision of the Council's chief engineer and at the sole cost of the company, and that any damage that may be done in or about the subway in the execution of the work shall be made good by the company to his satisfaction.

Folkestone.—It appears that the Corporation are more than likely to dispose of the powers of their provisional order. The committee thrashed the matter well out, and a resolution was moved that the Corporation themselves carry out the electric light within the borough, at a cost not exceeding £20,000. To that there was an amendment moved that the Corporation be recommended to treat with a company or persons, on terms to be arranged, for the disposal of the powers. The amendment was carried, and on its being put as a substantive motion, 12 voted for it and 3 against. A long discussion took place at the meeting of the Council, but eventually the committee's recommendation was adopted, and the report was referred to a committee of the whole Corporation.

Aberdeen —At a meeting of the Mechanical Society, Mr. L. L Horne, electrical superintendent for the Great North of Scotland Railway Company, read a paper on "Small Electric Plant." Mr. A. Sproule, president of the society, occupied the chair. Mr. Horne, at the outset, dealt with the advantages of electric light in prisons, workshops, and theatres, remarking that, after all, the places that derived most benefit from the light were hotels and large country mansions. Turning to the relative advantages of different systems, he gave numerous particulars regarding the various methods of generating the current, making special reference to the vexed question of the advantage or disadvantage of the use of accumulators; and, in conclusion, dealt with the cost of installation. A discussion followed.

Belfast.—At a meeting of the Law and Improvement Committee the report of the sub-committee appointed to visit several English and Continental cities and towns to make investigations into the question of electric traction for tramcars was read by the town clerk. It was a lengthy document, and contained many valuable statements, but no action was taken in the matter. A meeting of the Council in committee was subsequently held under the presidency of the Lord Mayor. There was considerable discussion as to whether or not the report of the electric traction deputation should be read at the meeting, and finally a vote was taken on the subject, with the result that the proposal to read it was negatived. The town clerk was then requested to have the report printed and circulated. The report recommends the adoption of the overhead system.

Electric Lighting in the Strand District.—A Select Committee of the House of Commons, presided over by Sir James Kitson, has passed a Bill which confirms a provisional order granted by the Board of Trade to the Charing Cross and Strand Electricity Supply Corporation, Limited, authorising them to light with electricity the area of the Strand District Board of Works The Bill has been opposed by the Metropolitan Electric Supply Company, Limited, who already supply the Strand district, but it was put forward in evidence that, whilst the Metropolitan Electric Light Company used the high-tension current, the Charing Cross Company would supply the direct low-tension current, which would be a great advantage to all who required electricity for motive power. This Bill has now received the sanction of both Houses, having passed the House of Lords before the dissolution.

Peterborough.—The borough engineer (Mr. J. C. Gill) has submitted his statement of the annual cost of working, and the income to be derived, to a meeting of the Council; but consideration of the matter was postponed to a special meeting. Mr Gill estimates that the annual expenditure on private incandescent lighting would be £2,407 and on public arc lighting £721. He states that at the end of the 25 years—payments on account of loan having ceased—electric current will be produced at the cost of 2d. per unit When working at full load, and charging 6d. per unit for the current, the proposed plant will not only provide the amounts to be paid off annually for purchase, depreciation, and cost of working, but will in addition to that leave a margin of £380 per annum. When the payments for loan shall have ceased the sum of £1,180 may be added to this, and the profit would be £1,560 per annum.

South Shields.—A pamphlet has been issued by Mr. Joseph A. Jeckell, the borough electrical engineer, giving to the intended consumers some information as to the advantages and cost of electric light The mains are now being laid, and will shortly be completed in the following streets: East Holborn, West Holborn, Corporation-street, Church-row, Dean-street, Market-place, King-street, Ocean-road, Fowler-street, Westoe-lane (from Wellington-terrace to Victoria-road), Victoria road, Cuthbert-street, Green-street, Laygate-lane (from Green-street to Trinity Church), and Laygate-street. Persons in these streets who are desirous of having the current laid on to their premises should at once communicate with the borough electrical engineer, who will be very pleased to give them any information on the subject. The price which the Corporation have decided to charge is 6d per unit but after a consumer has used his maximum demand on an average for two hours per day, he will obtain the rest at 3d. per unit.

Leicester.—At the Town Council meeting Alderman Lennard moved the adoption of that part of the Gas Committee's report relating to the finances of the electric lighting works. He said, looking at the revenue account, they had spent £33,709, having still unspent £9,038. 13s. That was unspent in a certain sense, for they owed £3,000 or £4,000 of that for work actually done but not yet paid for. On the revenue account the gross profit was £580 on the working of the half-year. That was gained by £1,273 being raised for current, £34 for the rent of meters, and £266 for fittings. Turning to the profit and loss account, they found themselves with a net loss of £195. 7s. 2d. on the half-year's working. Considering that this was only the second half-year, he thought it was exceedingly satisfactory. The net loss up to the present from the commencement of the department was £1,337. 17s 8d., and the total amount held on sinking fund account was £1,296, so that, looked at from one point of view, there had been no loss on the undertaking at all. The report was adopted.

The Electric Lighting of Great North Trains —At the annual meeting of this Company the chairman (Mr. W. Ferguson, LL D) stated that they had now fitted up five first and third class carriages and two composites with the electric light. The five run on the Dyce suburban service, and the two are available for the main line. The Dyce carriages have been running for some weeks with perfect satisfaction, and the others have just been put on. On their first trial they ran to Elgin with a clear and steady light all the way. Each carriage is fitted with a generator and an accumulator, and the power is obtained from the revolving axle of the carriage. The accumulator provides for the keeping up of the steady supply of electricity during the periods when the train is at a standstill at the stations. The cost is about the same as oil. After a fair trial, the directors continue to be satisfied with the light, and they will no doubt apply it to the bulk of their

Digitized by Google

plant. The apparatus is the invention of Mr. Gill, and the machines are supplied by Messrs. Stone and Co., of London.

Scarborough.—At the meeting of the Electric Supply Company last week, Mr. Swinton, referring to the saving that might accrue from adopting the electric light, read the following letter which had been received at the company's offices from Messrs. John Rowntree and Sons, 20 and 21, Westborough: "Dear Sir,—We send you, as requested, the following particulars of the cost of gas and electric light at 20 and 21, Westborough: cost of gas—1891, £38. 7s. 11d.; 1892, £34. 5s. 2d.; 1893, £36. 6s. 9d.; 1895, £8. 12s. 6d. gas and £20. 15s. 6d. electric light—£29 8s. We have 55 electric lights, varying from 8 c.p. to 32 c.p. Our premises are quite as well lighted now as previously with gas, though we have not increased the brilliancy. We have also added a gas-stove since putting in the electric light. The figures include the gas used for a small gas-engine, gas-stove, and two gas-rings. Practically, we use no gas for illuminating. This shows an average saving of over £5 10s. per year. We attribute it very largely to the care taken in not leaving the lights on when not required."

Hammersmith (London).—The committee dealing with the subject of electric lighting recommended the Vestry to appoint Mr. A. H. Preece as consulting engineer, and also recommended the acceptance of the tender of Messrs. Ferranti, Limited, for the sum of £12,302. 12s. The Vestry have adopted these recommendations. The Law and Parliamentary Committee reported having considered the letters from the London United Tramways, Limited, asking for the Vestry's consent to the provisional order promoted by them before the Board of Trade this session. By the order it is sought to exempt the company from the provisions of the London Overhead Wires Act, 1891, and the by-laws made under the Act, and to authorise the company, with the consent of the London County Council and the Vestry, to place overhead wires for working the tramways by electrical or other mechanical power, including the overhead trolley system of electric traction, or any other system. Having regard to the fact that the Vestry previously gave its consent to the company applying the overhead wire system to the tramways in Uxbridge-road, the committee now recommended the Vestry to give its consent to the present order. The report was adopted.

Liverpool.—The southern extension of the Overhead Electric Railway, which was entered upon last August, will in all likelihood be finished by August next. The extension begins about 150 yards north of the present terminus of the railway at Herculaneum Dock, and it consists of about 250 yards of iron viaduct and 800 yards of tunnel, both built for double line. The viaduct portion crosses Sefton-street, a corner of the Cheshire Lines goods yard, and part of the dock estate. Over the latter is a fine span of 220ft. The end of the extension is in Park-road, at the corner of the Dingle. To provide the additional power that will be necessary to work the extension and extra trains that will be required, two more engines and dynamos and new switchboard are being erected at the generating station, Bramley Moore Dock, which will then contain engines and dynamos capable of an output of 2,400 h.p. The new engines are being built by Messrs. Hicks, Hargreaves, and Co., of Bolton, and dynamos and new switchboard by Messrs. Thomas Parker, Limited, of Wolverhampton. The electrical equipment for the trains, which will consist of three carriages instead of two, is being constructed by the Electric Construction Company, of Wolverhampton.

Glasgow.—The Special Sub-Committee on Electric Lighting have reported that by the transference of the source of supply from John-street to Waterloo street station the cost of the electric light in the streets would be reduced to £22. 10s. 1d. per lamp, a saving of £6 10s. 4d. It has been agreed to request the students of the School of Art and the School of Design to send in designs for a wrought-iron bracket for continuing the existing lamps, and rendering them suitable for a pendant globe. The deputation appointed by the Corporation to obtain information in regard to the use of the electric light in various towns in England and Scotland have not yet completed their investigations. They visited Brighton, Portsmouth, and Blackpool. At the last meeting of the Electric Lighting Committee it was agreed that the officials of the committee should consider the question of the extended lighting of the city by electricity, and also investigate into the relative merits of gas lighting as compared with incandescent electric lighting for use in the subsidiary streets. In the meantime it was agreed to push forward the alterations of the lamps at the Charing Cross end of Sauchiehall-street, converting them from the present astragal form into hanging globes similar to those used in other cities. The committee felt on the whole question of the electric lighting of the streets that the effect of the Corporation having been comparatively early in the field was that they were suffering from many initiatory blunders that had been made, and that in carrying out further improvements they would profit by the experience they had gained.

Portsmouth.—The report of the Electric Lighting Committee presented at the meeting of the Town Council recommended that a joint committee, consisting of five members of the Electric Lighting and Roads and Works Committees, should be formed for the purpose of opening negotiations with the tramway company for the purchase of the tramway and for the leasing of the same to the company, and supplying the company with electrical energy for their cars upon terms to be mutually arranged, the committee to report progress to the Council. Alderman Ellis said the Portsmouth Company had gone to Parliament for power to run the overhead system of electric traction, and no doubt Parliament would grant their application, subject to the approval of the Corporation. His proposal was that the Corporation should purchase the plant and erect the necessary appliances, and then lease them to the tramway company at a rental of ½ per cent. over and above the amount the Corporation would have to pay as interest to the sinking fund. At the electric light station they had three huge engines, any one of which was capable of running all the cars in Portsmouth. At present the engines were working all day with no profit to the Corporation. He was sure that if the Corporation ran the trams they could hand over at least £4,000 or £5 000 a year to the borough funds. He admitted that the scheme would mean the outlay of a huge sum of money, but it would all come back to them in revenue. Last year every mile travelled by the trams cost the company 9d., and the takings for that distance amounted to 10d. If the scheme he had outlined came into force, he said the working expenses would be nearer 6d. an hour. Mr. Beale seconded, and the recommendation was carried.

Bristol.—It is stated that the advent of the electric tramcars has given a great impetus to the construction of dwelling-houses at St. George, Bristol. At a meeting of the Sanitary Committee the engineer reported an application of the National Telephone Company *re* their proposal of February 22 to place the main route of wires in the centre of the city underground. The engineer was of opinion that such a system would be desirable, as preventing in part the danger from overhead wires, and the necessity for unsightly posts. It had already been adopted by the Post Office on their trunk lines, and the committee had sanctioned several like applications from the Government department In those cases there had not been much trouble after the cables were once laid, but it might be a serious interference with the city traffic if the footways were constantly being taken up for extensions and repairs. The city electrical engineer reported that he had no objection to cables of the company being laid underground, as their currents could not affect those of electric lighting; but at the same time, as the company's wires would be close to those of the electric lighting department, the Corporation should be freed from all responsibility if their currents affected the working of the telephone wires. The company should be required to pay the wages of an inspector or inspectors from the electrical department to watch the progress of the work on behalf of the Corporation. A deputation from the National Telephone Company attended, and Mr. E. L Gane explained what it was the company required. In answer to a question from the chairman, Mr. Gane said by the laying of the main routes of wires underground some 50 or 75 per cent. of the overhead wires would be abolished. It was agreed that the district manager of the company should confer with the city engineer on the subject, and that a report should be presented.

London Lighting Extensions.—The Highways Committee of the London County Council have received the following notices under the Electric Lighting Acts and orders: two notices from the Metropolitan Electric Supply Company of intention to lay mains from the north-east corner of Lincoln's-inn-fields along the west side of Great Turnstile and a part of the north side of Whetstone-park, and along a part of the north side of Guildford-street and along the east side of Colonnade-mews; and two notices from the House-to-House Electric Light Supply Company of intention to lay mains on the east side of Queen's-gate from Harrington-road to No 114 and in Trebovir-road. In these cases the committee recommended that sanction be given. A notice had been given by the County of London and Brush Provincial Electric Lighting Company, under the County of London (North) Electric Lighting Order, 1892, of intention to lay mains on both sides of City-road between Old-street and Britannia-street. The greater part of the proposed works would be outside the company's area of supply under the order, and the Council have no power to approve of this portion of them. To avoid any misunderstanding, they therefore recommended that the Council formally disapprove the works referred to; that the company be informed that the Council have no power to sanction that part of the works which would be outside the area of supply under the County of London (North) Order, 1892, and that a fresh notice with plans should be submitted as regards that portion within the area of supply. The committee reported receipt of a notice from the Vestry of Hampstead, given in accordance with the provisions of the Hampstead Electric Lighting Order, 1892, of intention of lay mains in part of the north-east side of Shoot-up-hill, and part of the north side of Adamson-road. The Vestry was the undertaker under the order, and the Council had no power of approval or disapproval of these works.

Southampton.—The Corporation have decided to acquire the electric light and power company's undertaking. The matter has been arranged by the Works Committee, and their minutes which were read at the Council meeting, set forth the negotiations between the committee and the company. On March 10, in response to a letter received from Mr. James T. Hamilton, on behalf of the company, the committee resolved, "That the town clerk be instructed to point out, in reply to the communication, that the aggregate of the sums mentioned, amounting to £24,522, is practically the same sum as mentioned by the company's deputation on the 10th inst., and which the committee then informed the deputation they were not prepared to recommend the Corporation to entertain. That, without prejudice, the committee are prepared to recommend the Corporation to pay the company the sum of £20,000 as purchase-money for their undertaking and goodwill, and, in addition thereto, a reasonable sum for compensation to the directors and secretary for loss of fees and salary, and also the costs of formally winding up the company. That, with regard to these items, the committee are advised that the sum of £1,000 is ample, and this sum they are prepared to recommend. That the

Digitized by Google

town clerk be instructed to further point out that the company's provisional order does not authorise the company to supply electricity beyond the limits of the old borough, and it would therefore be necessary for the Corporation, even if they acquired their undertaking, to go to the expense of a provisional order to enable them to supply the area of the extended borough." Subsequently a letter was received from Mr. Hamilton stating that his board instructed him to accept the offer, subject to the following conditions: "(1) That the Corporation take over the company's liability on its debentures at par value in reduction of the purchase-money; (2) the Corporation is to take over the company's stores and stocks at a valuation, and to reimburse the company all capital expenditure since December 31, 1895; (3) the Corporation to take over all existing contracts entered into by the company." On this understanding the Works Committee recommended the Council to purchase the undertaking of the Southampton Electric Light and Power Company, Limited, for the sum of £21,000, such sum to include all preliminary expenses, goodwill, license, and provisional order, and the cost for charges and expenses to be incurred in winding up the company, and vesting the undertaking in the Corporation, and the Corporation to take over at a valuation the stock of stores of the company, and to reimburse the company the sum of £55. 18s, the amount of capital expenditure since December 31, 1895, and to take over the existing contracts for stores, coal, etc, entered into by the company, and that application be made to the Local Government Board for a loan of £50,000 to complete the purchase and to carry out the necessary extensions of the undertaking These recommendations were carried by 29 votes to 4, and eight members did not vote.

PROVISIONAL PATENTS, 1896.

MARCH 16.

5779. An improved automatic telephone switchboard specially adapted for private installations. Dennis McNamara, 3, Abercorn-terrace, Inchicore, Dublin.

5794. A new or improved manufacture of insulating material for underground electric wires, cables, or the like. Paul Raoul de Faucheux d'Humy, 6, Lord-street, Liverpool.

MARCH 17.

5872. An improved electric lift. James McLaren, Dersingham, Norfolk.

5874. Improvements in carbon pencils for the electric arc light. Thomas Cradock Hepworth, 10 Lysias-road, Balham-hill, London.

5884. Improvements in electrical switches. Robert Brymer, 70, Market-street, Manchester.

5951. Improvements in the suspension of motors for electric or other cars. James Devonshire, 70, Chancery lane, London. (Norman C. Bassett, United States.) (Complete specification.)

5980. Improvements in electric switches. Albert John Bonnella, 22, Southampton-buildings, Chancery-lane, London.

MARCH 18.

6001. A new form of vacuum tube for utilising the Rontgen "x" rays. Herbert Charles Newton, 3, Fleet-street, London.

6048. Improvements in controllers for electric motors. James Devonshire, 70, Chancery-lane, London. (William B. Potter, United States) (Complete specification)

6058. An improvement in electric primers for firing guns. The Morris Tube Ammunition and Safety Range Company, Limited, Charles Cuthbertson, and William Henry Stentiford, 28, Southampton-buildings, Chancery-lane, London. (Complete specification)

6068. Improvements in moderating electric incandescent lamps and apparatus for that purpose. Godfrey Bamberg, 33 Barcombe-avenue, Streatham hill, London.

6069. Improvements in the method of electrically coating wire and apparatus therefor. William Stepney Rawson, 21, Greycoat-gardens, London.

6071. Improvements in primary electric batteries. Walter Rowbotham, 45, Southampton-buildings, Chancery-lane, London.

MARCH 19.

6113. Improved apparatus for adapting telephone line wires for fire-alarm signals and similar purposes. Alfred George Burrell, 5, King street, Sheffield.

6148. Improvements in fittings for electric lighting. Henry Lea, 3, Cherry-street, Birmingham.

MARCH 20.

6197. A new or improved underground system of electric traction. Thomas Edward Doyle and James McKenny, 9, Westland-row, Dublin.

6208. Improvements in automatic electric switches. Arthur Ballance and Everett Hebden Hewson, 8, Quality-court, Chancery-lane, London. (Complete specification.)

6216. Improvements in and relating to the treatment of sodium and potassium chlorides by electrolysis. Charles Henry Parker and John Pullman, 65, Chancery-lane, London.

MARCH 21.

6269 Improvements in wooden and similar casings or mouldings for electric conduit wires and cables. Charles John Wightman and Arthur Hudson, 2, Market-street, Bradford.

6305. Improvements in surface trolleys for electric railways. William Sharkey Hull, 323, High Holborn, London. (Complete specification.)

6306. Improvements in electric motors Arthur Greenwood, 6, Bream's-buildings, Chancery, London.

6329. Improvements in apparatus for producing, storing, and applying electricity, especially applicable to the lighting and heating of railway carriages and other vehicles. Edwin James Preston (of the firm of J. Stone and Co) and Arthur Bernard Gill, 77, Chancery-lane, London.

SPECIFICATIONS PUBLISHED

NOTES.

Telautograph.—It has been stated in the *St. James's Gazette* that the telautograph is about to be adopted by the National Telephone Company, in addition to their ordinary service.

Personal.—We were pleased on Monday last to receive a call from Mr. Gisbert Kapp, who is paying a hurried visit to London. He informs us that the Verband Deutscher Elektrotechniker, of which he is secretary, is doing good work for the profession in Germany. Amongst the recent work of the society, the wiring rules deserve special mention. In these the radical departure of forbidding the use of wood casing has been made.

What, When, and Where.—The general meeting of the Chesterfield and Midland Counties Institution of Engineers is fixed for to-morrow (Saturday, April 4) at Derby. On Wednesday, 8th inst., the students of the Institution of Civil Engineers are to visit the works of the Waterloo and City Railway, assembling at 15, Upper Ground-street, Blackfriars, at 2.30 p.m. On the same date there will be a meeting of the shareholders of Willans and Robinson, Limited, at the Cannon-street Hotel, at 3 p.m.

Parisian Installations. — The Paris Bureau de Controle, which periodically looks after the electric installations of its subscribers, reports that its inspectors have paid 426 visits and presented the same number of reports. It is stated that a great number of installations—more than half—were found more or less defective—otherwise, what would be the good of the bureau ?—and have been put right. The bureau has also undertaken to determine the actual efficiency in watts per candle-power of incandescent lamps. That is a thing the consumer decidedly wants to know.

The Metric System.—At a recent meeting of the council of the Leeds Chamber of Commerce a letter was read from Sir Albert Rollit, M.P., to Colonel Harding—which the latter desired should be communicated to the chamber—on the subject of the metric system. Sir Albert stated that he had seen Mr. A. J. Balfour with regard to the adoption of the system, and the right hon. gentleman had said that it was a subject he had promised to consider, and, having done so, he was in favour of the metric system being adopted, and thought his colleagues in the Cabinet would be guided by his advice.

Liverpool Electric Railway.—On Monday, as previously announced, the Duke and Duchess of York, who were visiting Liverpool, took a trip on the overhead electric railway. At the station the party were received by Sir William Forwood and others, and on the platform the Duchess of York was presented with a bouquet by Miss Forwood. At five minutes to one o'clock the party entered a special train and proceeded north to the extreme end of the docks, and then south to the Herculaneum Dock, returning about ten minutes past two to the Custom House Station. The ordinary traffic along the line was suspended.

Motorcars.—It is stated that a horseless carriage competition has been organised by the *Cosmopolitan* magazine in New York for a prize of £600, and the services of a distinguished committee of judges have been secured. The award will be made upon the following points, the maximum being 100: speed, 35; simplicity of construction and durability, 30; ease in operating and safety, 25; cost, 10. Fifty-two miles will be covered in the test, over excellent roadway. The names of the judges are General Miles; Mr. William P. Craighall, chief of Engineers, U.S. Army; Mr. H. Walter Webb, vice-president N.Y. Central and H.R.R.R. Company; and Mr. John Jacob Astor. The date of the competition is May 30.

Geneva Electrical Congress.—It has been stated by *L'Elettricità* that the electrical congress which it is proposed to hold this summer at Geneva, on the occasion of the exhibition there, is to be of a practical rather than a scientific character. It is to last about four days. Only morning sittings will be held, so as to leave the afternoon free for visits to the exhibition. A dinner, excursions, and visits to some of the large water-power installations are to be arranged for. The fee is 20fr., which will include entrance to the exhibition; but all arrangements are contingent upon a sufficient number of subscribers presenting themselves.

Carbide of Zirconium.—In a note presented to the Paris Académie des Sciences by Messrs. H. Moissan and Lengfeld, a description is given of a carbide of zirconium prepared by means of the electric furnace. It is a crystalline substance of a composition corresponding to the formula ZrC, and is not decomposed by water. It is remarked that this is somewhat curious from a theoretical point of view, since the carbide of thorium, which belongs to the same set of elements in Mendeleieff's classification, decomposes water with the production of hydrogen and hydrocarbons in the usual way. In reference to this, even if thorium is rightly placed, it must be remembered that zirconium lies much nearer to silicon and carbon itself. The carbides of the intermediate elements may possibly bridge the gap.

Cable Interruptions. — From the list of cable interruptions for last month published by the Bureau International des Administrations Télégraphiques in the *Journal Télégraphique* of March 25, it appears that the Zanzibar and Mombasa cable broke down on March 6. Communication was re-established on the 9th, but the Aden and Zanzibar section failed on the 16th, and had not been renewed up to the date of publication. An interruption of the Ceara-Pernambuco cable on March 3 was repaired the same day. The two interruptions of old date on the Brest to St. Pierre cables, as well as those of the Puerto Plata and Martinique, dating from December 19, and the South African Transcontinental land line beyond Mazol, come also in the list of "communications not re-established."

Water Power.—According to reports from America, Mariposa County, California, is to have one of the largest electrical power developing and distributing plants in the United States. It will be at the Horseshoe Bend, on the Merced River, near the centre of a mining district having at least 100 mines that are sufficiently prospected to use cheap power. At the driest season of the year the power company reckons upon 1,800 h.p., and during eight months in the year they expect water enough to generate 3,500 h.p. The price the company proposes to charge its customers is £1 per horse-power a month. At the present time the expense of producing steam is from £2. 8s. to £3 per horse-power, and two years hence, at the present rate of consumption of wood, the hills would be bare of timber, and steam power, except in a few localities, at a price almost prohibitive.

Imperial Institute.—Her Majesty's Commissioners for the Exhibition of 1851 have just considerably increased their annual grant in aid of the work carried out in the department of scientific and technical research of the Imperial Institute, and the executive council of the institute have consequently decided to take active steps for the development of this department. A laboratory having been fitted up, and, as far as possible, equipped in 1894, with the aid of funds provided for that purpose by the Goldsmiths' Company, the operations of the scientific department commenced in October of that year under the temporary direction of Sir Frederick Abel. The council

Digitized by Google

of the institute have now appointed Prof. Wyndham R. Dunstan, M.A., F.R.S. (hon. secretary of the Chemical Society), as director of this department, to the staff of which other additions are contemplated.

Lighting a Channel.—Dr. E. L. Corthell has described briefly in the *Scientific American* the system of electrically-lighted buoys used to mark out the channel into New York Harbour. Originally a direct current was used, but this was changed to an alternating current, and the size of the conducting cable reduced from 1⅛in. to ·78in. The experience gained at Chicago with a cable laid in the water from the Exposition to the city, about seven miles, and further study and experiment, led to the very satisfactory method only recently installed at Sandy Hook, as mentioned above. The spar buoys used are juniper wood 50ft. long, held in place by mushroom anchors weighing 4,000lb. The lamps, which are attached to the top of the buoys, are 100 c.p. of a new design, with 5in. globes. The length of the cable used is about 6¼ statute miles, with an additional length of nearly two miles to the South-West Spit Buoy.

Roman Trams.—In the course of a discussion at the Society of Arts following on a paper by Mr. Parshall on electric traction, Mr. W. H. Preece referred to the application of electricity to lighting and tramway working in Rome which he had recently inspected. The current was generated 18 miles off, at Tivoli. The water power there worked six turbines, giving in all 2,000 h.p. This was converted into alternating currents at an equivalent of 6,000 volts and transmitted to Rome, where it was transformed down to 110 volts and used for lighting. The day load remained available to work the tramways. The alternating currents were transformed down, rectified, and used to charge a very large accumulator of 304 cells and 1,200 ampere-hour capacity. During the day the trams were worked direct, and the accumulator was used to carry over the period during which the tramway service and the lighting overlapped, as well as to maintain a constant pressure at other times.

Electric Dredger.—According to the *Schweizerischen Bauzeitung*, trials of an electrically-driven dredger have taken place at the yard of Messrs. A. F. Smulders at Slikkerver, Rotterdam, which are of some interest. The design is due to Mr. Bunan Varilla, and the dredger is intended for excavating work in the bed of the River Esla in Spain. The plant includes a 150-h.p. steam-engine and a three-phase generator with stationary armature and rotating field. The potential is 2,000 volts, and the current is taken from the river bank to the dredger by a cable, and there transformed down to 200 volts. All the work of the dredger is done by motors, so that the crew is reduced to a minimum and the draught of the boat is very light. This is obviously an important matter in a dredger. In reference to this craft the *Elektrotechnische Zeitschrift* reminds its readers that at Jena there is at work an electric dredger which excavates gravel and sand for industrial use from the bed of the River Saale.

Small Station Steam-Engines. — Prof. R. C. Carpenter, in the course of a long article in *Cassier's Magazine*, has discussed the question of the proper steam plant for a small electric light and power station. He prefers automatic—*i.e.*, slide-valve—to throttle governing. The main trouble in selecting an economical engine is to provide for the varying load, as the economy which may be obtained with engines of the poorest type when fully loaded is better than that with engines of the best type having a very light load, so that it may be advisable to suffer the loss of several small engines working at fairly good loads than from one large engine working with very light loads. In the case of an electric railroad station, where the change of load is almost instantaneous, the most satisfactory method seemed to be to use so small an engine that it should be operated in a condition usually considered an overload when meeting the maximum requirement. This will involve a heavier crank-pin, shaft, piston-rod, etc., than the usual practice warrants.

Steam Warping.—Ever since 1856 steamers have pulled themselves along the River Seine between Monterean and Rouen by hauling in and paying out behind a chain running along the bed of the river. Mechanical difficulties immediately present themselves in the way of securing a sufficient grip of the chain to prevent slipping on the windlass without at the same time so tying the steamer up to the chain, that passing is rendered dangerous and difficult. The method of progress is an exceedingly economical one, especially where heavy loads have to be towed, and it is probably the difficulties alluded to that have prevented this system of river navigation spreading outside France. In the *Revue Générale des Sciences* it is, however, stated that Mr. de Bovet has got over the trouble by using a magnetic windlass about 47in. in diameter, around which the chain makes only three-quarters of a turn, and from which, therefore, it can be much more easily removed. Three vessels have been fitted in this way, and the results are said to be entirely satisfactory. Two subsidiary pulleys, one of which is also magnetisable and in gear with the machinery, keep the chain in contact with the main pulley. A current of 35 amperes, giving an equivalent of 28,000 ampere-turns, is stated to be used, but no details are supplied as to the winding.

American Patent Disputes.—The fight that has been going on in the United States between the General Electric Company and the Westinghouse Electric and Manufacturing Company has at last ended in a compromise. For nearly a year those largely interested in the two companies have been endeavouring to come to some arrangement which would reduce the competition between the two concerns, which are the largest manufacturers of electrical appliances in the country. The rivalry between the companies has been great, and it is said that the patent litigation between the two companies has cost several million dollars in legal expenses and for the services of experts. The result of this litigation has been to increase competition, lower prices, and benefit many smaller concerns. It is now stated that an arrangement has been made for a joint use of the patents of the two companies, subject to existing licenses, on terms which are considered mutually advantageous, and the patents are to be managed by a board of control, consisting of five members, two appointed by each company and a fifth selected by the four so appointed. The especial incentives which have led to the arrangement are the recent decisions in favour of patents of the General Electric Company controlling the overhead system of electric railways, the approaching trials on a number of other important General Electric patents on controllers and details of electric railway apparatus and systems and other electrical devices, and the equally strong position of the Westinghouse Company in respect to power transmission, covered by the patents of Mr. Nikola Tesla and others.

Junior Engineers.—A conversazione was given on Saturday night at the Westminster Palace Hotel by the Institution of Junior Engineers, and was well attended. The guests were received by the president (Mr. Archibald Denny, M.I.N.A.) and the chairman (Mr. H. J. Young) and Miss Young. So far as the exhibits were concerned electricity was very much to the fore, at least one-third of them being electrical. Not to mention Mr. Wimshurst

Digitized by Google

and his machine, there were apparatus for electric welding, electric cooking, postal telegraph instruments from the General Post Office, while the electrophone-room was in connection with about eight of the theatres. The new photography is now a matter of course everywhere, and a quantity of Mr. Campbell Swinton's work was shown, and the process demonstrated, while upstairs Mr. Leslie Miller exhibited an instrument equivalent to Prof. Salvioni's cryptoscope, or, as it now seems in danger of being called in this country, a crytograph. Though the circumstances were somewhat unfavourable, this was a popular and successful exhibit. For the rest, Mr. Robert Paul showed his theatrograph, mostly pictures of dancers, on the principle that if the theatrograph can do a skirt dance it can do anything. Mr. E. Basil Wedmore showed his four-pendulum harmonograph, not the least interesting part about which is the way Mr. Wedmore makes silk threads do the work of universal joints, and uses grooved drawing pins and wood screws where one would expect a knife-edge and agate plate. There were short concerts of instrumental and vocal music, including violin solos by Mr. T. E. Gatehouse, songs by Miss Lane, Mr. Kenneth Gray, and humorous musical selections by Mr. H. H. Preston, in addition to a programme of music by Mr. W. Day's band. When there was not music, Mrs. Lynd showed the Edison-Bell phonograph.

Electric Railway Traction.—In the course of a series of articles in the New York *Electrical Engineer* on the subject of electric traction on railways, Mr. Baxter discusses the coal consumption on steam and electric railways, and estimates that the coal consumption of locomotives will average 4lb. per horse-power per hour for express engines, 5lb. for local passenger and 6lb. for freight trains. The cost of a unit of energy developed on the track by electric motors would be about 44·5 per cent. of what it is with steam locomotives as far as the coal bill alone is concerned, and therefore the saving in favour of electricity would be less than 2¼d. per train mile. As the average yearly run of a locomotive in America is about 30,000 miles, the annual saving in coal per locomotive would be over £260, which, however, is not considered to be enough to make the adoption of electricity justifiable on existing railways. Nevertheless, the incidental advantages of electric traction, taken altogether, would go far towards offsetting the cost of power stations, trolley lines, and feeders, and in equipping a new line would leave only a small percentage in favour of steam, so small, indeed, that the reduced cost of operation due to the saving of coal would render the electric system more profitable, except where coal is very cheap. From the reports of 10 of the largest railways it appears that the percentage of the coal bill to the total operating expenses averages about 10 per cent., being as low as 6 in one case and as high as 18 in another. The coal consumption of freight locomotives is much greater per horse-power than the figures claimed for high-speed passenger engines, and therefore it would seem that the opinion generally entertained that electricity would not have much of a chance competing with steam for freight service is not well founded. On the contrary, Mr. Baxter contends that if it can compete with steam at all it will be for heavy freight traffic. On account of the slow speed of freight locomotives their efficiency is much lower, and in addition to this such locomotives are often side-tracked for a considerable time, during which a certain amount of coal is burnt without doing work.

Resistance of the Arc.—A number of experiments have been described by Dr. Arons in *Wiedemanns Annalen* which have a bearing on the question whether there is a counter E.M.F. in the electric arc. Stenger some time ago connected a galvanometer in series with the arc, and arranged it that the needle could deflect only in the opposite direction to that produced by the original current. On short-circuiting the dynamo no deflection was produced in the galvanometer by the action of the supposed counter E.M.F. When, however, some accumulators were put in circuit, which were charged by the original current, they produced a strong current under the same circumstances, and he considered this a proof that there was no counter E.M.F. in the arc. Dr. Arons, however, thought this was not conclusive, as the limit was not found of the E.M.F. of the battery which the voltage must have to produce the currents between the carbons, and made researches to find this limit. That there was such a limit, he concluded from the fact that an alternating arc between the carbons was possible. With a resistance of 0·4 ohm, 18 volts of the accumulator battery was necessary to produce a deflection of the galvanometer—that is, to pass a current through the gaseous space between the carbons; to produce an arc in the opposite direction 30 volts were required, but the arc continued only for a few seconds. For a continuous arc 70 volts were required. From this he concludes that there is a counter E.M.F. which vanishes very rapidly. With metallic electrodes no signs of a momentary current after short-circuiting could be obtained, even though the voltage of the battery was 76. From this it would seem to follow that an alternating arc between metallic electrodes was not possible, unless the voltage reached that required for sparking across. Between carbon and metallic electrodes an alternating arc can be maintained, the light from which shows the lines of that metal in the spectroscope. Dr. Arons' conclusion is that as the heat conductivity of the carbon is less than that of the metals, its temperature on striking the arc is higher, and that between glowing electrodes a current will be produced even with comparatively low voltage, and it is possible that these weak currents allow the arc to continue. Metals produce only their own vapours, while carbon gives off gases which will probably last longer than the vapours of the metals. Again, the whole of the products of the carbon are gaseous, while the metallic electrodes are soon covered with oxidising, non-conducting layers which may possibly act to prevent the arc from relighting.

Cold Light.—In the course of an article in the New York *Electrical World*, Mr. W. M. Stine discusses the conditions, so far as they are known, that would have to be complied with in order to produce light radiations alone without the accompaniment of an altogether disproportionate quantity of invisible vibrations of lower period. The problem is to produce ether waves with periods between 400×10^{12} and 750×10^{12}. To produce "cold light" it will not suffice to merely set up transverse vibrations in the ether, but such vibrations must be strictly controllable within the limits of visible rays. As to the possible methods of impressing such disturbances on the ether, given matter and ether, how may the former affect the latter? According to ordinary views of the ether, waves in it can have but small amplitude, and can therefore be established only through the agency of molecular and not molar masses. What may be termed the inertia-time-constant of a molar mass, however small, is too great to set up true ether waves. In such cases the ether must simply flow around the moving mass. As well might sound waves be attempted by moving a door rapidly on its hinges. The problem thus narrows down to the molecule, which is sufficiently rapid in its movements to exceed the inertia-time-constant of the ether particles, which thus suffer a true displacement rather

Digitized by Google

than a movement of flow around the disturbing matter. Could the molecule be given a governable period of vibration, the problem would be nearer solution. Spectrum analysis shows that the molecules of the different elements have a very different capacity for vibration in different wave periods. In other words, some spectra have few and others a great number of lines. Unfortunately, when energy is imparted to molecules to render them luminous, the greater part of the energy is radiated in waves of large magnitude and long period or heat waves. Light, so far as is known, is only the result of a molecular impact or collision, so it would seem impossible on such lines to avoid heat waves. It must be further emphasised that the light-producing molecules must not be gaseous, but constituents of very minute solid particles, since the total mass of a gas is too small to transform any considerable amount of energy or produce a light of much intensity. In illumination by fluorescence the vibrations are set up by impact of rapidly-moving gaseous molecules on those of a solid. This gaseous bombardment must necessarily be associated with a certain heat waste. On the other hand, the direct production of ether waves by an alternating electric charge would seem to require apparatus of dimensions as small as a molecule, so that this method would appear to be hopeless.

Rontgen Radiations.—The surprises of the new photography are by no means exhausted. The last is contained in a letter written by Messrs. L. J. Atkinson, A. H. Pook, and R. P. Williams to *Knowledge*. On exposing a plate enclosed in an ordinary cardboard plate-box "with the object of obtaining a shadowgraph of keys, coins, etc., on the top," these gentlemen failed to obtain the usual image, but on exposing another plate in the same box, after a trifling alteration of apparatus but with an entirely different set of objects, a good image was obtained, not of the second set of objects, but of the first. A similar result was secured when an interval of as much as eight days was allowed to elapse between the two exposures, and the box was in the meantime exposed to strong sunlight. Curiously enough, the effect was only to be obtained with that particular box, and endeavours are being made to obtain more like it of the same batch. All that can be said on the subject at present is that the transmission of the Röntgen effect through that particular box involves some process entirely different from the transmission of ordinary light radiations. If so, any amount of theory goes at once. It is, of course, possible to invent an explanation by supposing a molecular change to take place which renders an originally opaque substance ultimately transparent, and which, on the basis of a gradual breaking down under continued battering of the molecular grouping that opposes the passage of the radiations, would undoubtedly require a definite time to accomplish. But in that case, a superposed image of the second group of objects would be obtained, which does not seem to have happened, and the plate-box would then always give normal images. It is, however, better to wait for the further experiments which are promised, and from which the discoverers of this remarkable phenomenon hope to elaborate a definite theory of it. It may be noted that the same issue of *Knowledge* contains some very beautiful reproductions of Röntgen photographs produced by Mr. J. W. Gifford. Incidentally, it appears that that gentleman is by no means inclined to abandon as hopeless the hypothesis that the Röntgen radiations may be, as was here suggested at the beginning, merely very long waves, though not so long as the Hertzian waves. The actinic effect he considers to be due to overtones of these waves set up in the sensitive plate. Attention may be called to the discussion at the Physical Society on the "Edison effect," which has considerable bearing on the nature of the cathode rays and what really takes place in a high vacuum subjected to electrical stress. Before leaving the subject it may be added that Prof. Oliver J. Lodge has written to the *Times* stating that at Liverpool the new radiations have been transmitted through the bodies of two men standing one behind the other, and that Röntgen photographs of an injured vertebra and an intestinal lesion have been obtained at the Liverpool Royal Infirmary after exposures of half an hour and 10 minutes respectively. A "focus tube" and a powerful ordinary induction coil were the means used.

The Metric System.—In the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders there is published a communication by Mr. G. H. Baines on the report of the House of Commons Committee on the metric system. It is pointed out that evidence was given before the committee by about 20 witnesses representing official, commercial, manufacturing, trade, educational, and professional interests, and these were practically unanimous in favour of the change. The engineers included Mr. Alex. Siemens, Mr. Emerson Dowson, Captain Sankey, and Sir Benjamin Baker, all of whom favoured the change, while Sir Frederick Bramwell proposed to have the old and the metric system running side by side. Lord Kelvin's testimony was that the present was a "brain-weakening and time-wasting system which ought to be abolished." Mr. J. C. Stevenson, who is connected with both the chemical manufacturing and shipping interests, was the only member of the committee who was opposed to the metric system. His idea was to take the existing foot, gallon, and pound and use decimals of these, all other measures to be dropped. This would do very well if we had no foreign trade to consider, but when the change is made it may just as well be such a one as will not make it necessary to have one set of patterns for home and another for foreign use. It may be added that the London Association for the Protection of Trade, which has about 4,000 members, the majority of whom are retail traders, has sent a petition to Parliament urging that the recommendations of the Select Committee should be adopted. The Rochdale Merchants' and Tradesmen's Association has petitioned outright for the compulsory adoption of the metric system. The Edinburgh Merchants' Association, the Hull Guardian Society, the Association of Trade Protection Societies, the Manchester Guardian Society, and the Munster Merchants' Associations, all representing retailers rather than merchants, have expressed themselves in favour of the change; and similar institutions in Heckmondwike, Wimbledon, Southam, Bolton, and Merthyr Tydfil have passed resolutions for the adoption of the metric weights and measures. In Liverpool the Cotton Association, Corn Trade Association, General Brokers' Association, Salt Chamber of Commerce, Shipowners' Association, West India Association, Woolbrookers' Association, Warehouse Association, Provision Trade Association, and the Iron and General Metal Trades Section of the Liverpool Chamber of Commerce have expressed themselves in favour of the recommendations of the Select Committee. From all this it looks as though something might be done at last. Whatever could be said for them on their merits, it is obviously too late for proposals like Mr. Stevenson's. The few outstanding nations are fast adopting the metric system, so that soon England and the United States will stand alone in resisting it. The last adhesion is that of Turkey, and in order that the change there should be a real and not a nominal one, the local authorities have received instructions to call together the various trade corporations

Digitized by Google

in order that they should provide themselves with weights and measures in conformity with the new system.

The Baltimore Electric Locomotive.—In the New York *Electrical World* some interesting information is given as to the results of trials made with the electric locomotive used for hauling trains through the Belt Line tunnel of Baltimore. By its means a reduction of 16 minutes in the running time of the "Blue Line" trains between New York and Washington is now made possible, and it is probable that this saving will be increased later on. Probably the most striking test of the power of the locomotive was when two trains were coupled together and hauled through the tunnel. For some reason the freight trains had become "bunched" on the Washington division, and when they did get through they came so fast that it was decided to have the electric locomotive haul them two at a time. The first composite train, therefore, consisted of 44 cars, loaded with coal and lumber, two regular steam freight engines and a steam "pusher" engine. The whole weight was approximately 1,900 tons, and was equivalent to about 52 loaded cars. The steam locomotives did no work to assist the electric locomotive. The start was made easily and gradually, but when the train was in the tunnel and entirely on the grade the steady, heavy pull was too severe on a defective coupling near the head of the train, and it parted. After coupling together again, the electric locomotive started the heavy train, with all drawbars stretched—no slack in the train—and accelerated it to a speed of 12 miles an hour without slipping a wheel, and in every way with the greatest ease. It reminded one of the start of an ocean steamship, so noiseless was it and free from any manifestations other than those of mighty power. The current recorded on the ammeter was about 2,200 amperes during the acceleration period, and after the train was up to speed it settled down to about 1,800 amperes. The voltage on the line was 625. By reading the amperes the drawbar pull was readily computed and found to be about 63,000lb. All four motors were in series. The conductor in the tunnel has now been in position for nine months. During all of this time coke-burning locomotives have been used for passenger service with the consequent presence of a good deal of gas and vapour. Current was first turned on the line about three months after the tunnel structure was erected. The leak at first was about 21 amperes, but in a day or two this dropped to about four amperes—the present leakage. The inside of the conductor became coated with a combined deposit of rust and muddy sediment. Heavy currents were taken from it by the contact shoe only with difficulty and the presence of much arcing, heating, and showers of sparks. By applications of kerosene and frequent scraping with special shoes, a direct contact of the trolley shoe with the conductor was made possible. Although a single-contact shoe then worked with little or no sparking, two shoes in tandem were adopted. At intervals of about three weeks the conductor is now treated with kerosene, and brushing shoes are run through it. About one or two trips with these brushing shoes are all that is necessary, and this serves to prevent further accumulation of rust and to remove the sediment from the contact surfaces. No considerable sparking now occurs, except at the wet places, where it is occasioned by the presence of water and sediment. With the exception of three places, about 200ft. long each, the conductor is at present dry.

Electric Power in Gold Mines.—A short time ago the *Financial News* published an article on Barberton mining, in the course of which it was mentioned that the experimental crushings of gold ore had been hampered by want of water, and also by the uncertainty of the electric power used to drive the stamps. Further, it was said that steps were at once to be taken to substitute steam for the electric power now used to actuate the battery; electricity had been adopted, not because it was the best form of power available, but because Moodie's Exploration and Gold Mining Company was willing to put up an experimental installation, and the Fortuna people gave it a fair trial. They found that it is not to be depended on, and is not adequate for the requirements of the mine. These remarks drew from Mr. W. B. Esson, M.I.C.E., M.I.E.E. (chief engineer to Messrs. Johnson and Phillips), who erected the plant at the Sheba Mine, a letter to show that, properly engineered, power transmitted electrically can be made as reliable as power obtained by any other means, steam included, and that the uncertainty of the electric power at the mine in question, due to whatever cause, cannot be held as condemning in any sense the use of electric power generally. He says that by a curious fate the Sheba Mine, which might be called next door to Moodie's, has also an electric plant, and has for 12 months depended solely and absolutely for its crushing on power transmitted electrically. By a still more curious fate, while Moodie's Fortuna records a failure, the Sheba has recently recorded crushings which have been unprecedented, and which bear ample evidence of what electric power can do. The difference in results may to a large extent be attributed to the fact that at the Sheba Mine two alternating currents are used, while a direct current is used at the neighbouring mine. "The results at Sheba speak for themselves. The electric power is transmitted through cables five miles long, and the mill works night and day, never stopping save for an occasional examination of the machinery at the generating or receiving end of the lines. For the four months ended February 29 the mill worked night and day, with stoppages aggregating in that time only one day and a half in all. The record as it stands forms an undeniable tribute to the success of power transmission by electricity, and it will be obvious that what has been done at Sheba can be done elsewhere, if the problem be tackled in the right manner." Following on this came a letter from Mr. H. K. Baynes, on behalf of Messrs. Easton, Anderson, and Goolden, Limited, endorsing Mr. Esson's remarks. Mr. Baynes says that "to supply any plant, whether the motive power be electricity, steam, or anything else, it is necessary to know beforehand the conditions under which it is to work and the amount of power required. Neither of these factors were known in the case of Moodie's. The calculations as to the quantity of power required were prepared at Barberton, and embodied in a specification, and the plant supplied by Messrs. Goolden and Co. was designed to produce, and, in fact (as certified by Moodie's consulting engineer), produces the quantity specified. It now turns out that these calculations were quite incorrect, and that the quantity specified is altogether insufficient for the work required. Thereupon the uninitiated hasten to fall foul of electricity as a motive power, forgetting that as they cannot expect 50 h.p. out of a 5-h.p. steam-engine, so they cannot hope to extract from a dynamo or motor more current than it is constructed to supply. They should address their complaints to the gentlemen who are responsible for the miscalculations in question, and not to the contractors, who supplied exactly that which they were asked to supply." With every possible deference to our contemporary, we would suggest that the whole question is which is the easier to get, coal or water power. Neither are particularly cheap at Barberton. There is no difficulty in making an electric motor to work quartz crushing stamps.

ELECTRIC TRACTION ON RACK RAILWAYS.

BY FRANK B. LEA.

There are several reasons why the use of electric energy as the propelling power on rack railways should offer great attraction to the engineer as well as the management.

In the first place, the adoption of rack working implies grades too steep for ordinary adhesion locomotives—that is, implies that the line in question is situated wholly or largely in a mountainous region. Therefore, it may safely be concluded that in seven cases out of ten there is a tolerable amount of water power close at hand which can be brought into service at small initial expense to furnish a very cheap supply of energy for the trains.

Secondly, the weight of locomotive when operated by electric energy may be, and usually is, very much less than when steam power is employed, seeing that neither boiler nor tender, with coal and water, is required. This leaves, accordingly, a greater weight for the train load, and a larger net paying load, for a given locomotive horse-power, other conditions being also equal.

In the third place, it is characteristic of most mountain lines to possess a considerable amount of tunnelling. The difficulty of properly ventilating tunnels, especially on single lines, where traffic perhaps runs first one way, then another, is notorious when steam locomotives are used, and time after time complaints are made of the smoke and fumes found in these tunnels, both by passengers and railway staff. All such trouble is avoided by the use of electric locomotives, and their employment on this account alone has been suggested more than once on lines where long tunnels exist.

Although the facts thus detailed may appear to have more particular interest to the engineers of countries like Germany and Switzerland, where rack railways are almost as numerous as visitors to ride upon them, there are yet many places in England, its Colonies, and dependencies where rack working is quite as possible and desirable as on the Righi or the Harz. One of the latest projects in Switzerland has, however, peculiar attractions from its very boldness, and a little attention may therefore be worth giving first of all to the proposed line up the Jungfrau—a mountain that has not, perhaps, the savage sternness of the Matterhorn, but which, for all that, is not a pleasant promenade for the amateur.

The greater part of the Jungfrau line is to be in tunnel, and therefore the use of electricity becomes almost essential if passengers are to be carried with any degree of comfort, not to say pleasure. The first mile and a half is open, and the tunnel which follows has a length of 6·2 miles. Of course the object of tunnelling is to obviate all danger from avalanches or rock falls. The grade—25 per cent., or 1 in 4—is not steeper than that of many other rack lines already operated with success, as, for instance, the Pike's Peak, Rothhorn, and Mont Salève. The last named is worked by electricity, as will doubtless be remembered; but the two former, like most of the existing rack lines, are operated by steam locomotives with combined rack and adhesion mechanisms—that is, two separate sets of cylinders and gear are provided, one to work the rack wheels, the other the adhesion wheels, though, of course, the chief work of hauling is done by the former.

The average speed proposed for the Jungfrau line is five miles per hour, but it is hardly probable that this will be attained in practice; four miles per hour ought to be the *maximum* speed attempted. A total gross train weight of 20 tons would require at the latter speed 120 h.p. to raise it over the grade above mentioned; and of the 20 tons about six tons would represent the weight of motors and gear mounted on the car and capable of giving this output. This allows nine tons for the car, which should for this weight be equal to a capacity of at least 50 passengers. It is doubtful whether the net paying load would in any case be more than about 20 per cent. of total train weight, but the difference between electrical and steam lines, in favour of the former, will be noticed at once when figures for the latter are given. Take, for example, the Rothhorn line, with equal maximum grade—viz., 1 in 4. Here the steam locomotive weighs 17½ tons and the train 8½ tons, making a total of 26 tons for a maximum net paying load of not more than about 3½ tons, equal to only 12½ per cent. of the total. The same conditions apply to other lines of this kind—*e.g.*, that at Schafberg (Austria), with engine weight of 17·3 tons, and train weight of 10 tons; the Generoso line, engine weight 15 tons, train weight 10 tons (accommodating 56 passengers); and, lastly, the Mont Revard (Aix-les-Bains), with engine weight of 17 tons and train weight 10 tons, carrying 60 passengers. All these lines have a similar grade to that proposed for the Jungfrau. The Pike's Peak line is slightly more favourable to steam traction, though still far less efficient than if operated by electricity: the engine weighs 24 tons and the train weight 19 tons, carrying 100 passengers, or a proportion of, roughly, 14 per cent. for the net live load.

As might be expected, there is ample water power available for the proposed Jungfrau line, a waterfall capable of giving at least 5,000 h.p. existing about five miles from the starting point of the line. The length of circuit out and home would therefore be nearly 23 miles. So far as the rail return circuit is concerned, the ohmic resistance for all rack lines is almost negligible, seeing that not only is the whole understructure—rails and sleepers—metallic and interconnected, but the rack itself forms an additional conductor of no small area. The distance mentioned is not too great for the use of ordinary direct currents, for although the drop of voltage must be heavy for a reasonable size of conductor, yet the source of power being so inexpensive energy can well be wasted in line resistance. The use of a "booster" dynamo at the power-house would overcome any excessive fall of pressure in the furthermost line section, involving reduced speed in the motors. At the same time, this installation if carried out should afford a very good opportunity for the partial, if not complete, use of polyphase alternating currents. Three-phase generators in the power-house would allow of a high pressure and small mains across the five miles intervening between the source of energy and feeding point of the line (just as in the case of the Dublin electric tramway), a transformer station being erected at the point connecting with the line equipped either with motor generators for direct-current working after the usual fashion, or with simple static transformers operating three-phase motors on the cars or locomotive. In the latter case, two line conductors and trolleys, or sliding contacts, are necessary, the rails forming a third conductor.

Lines of somewhat similar character, differing, however, in so far as they are almost entirely in the open, are those building or proposed for Snowdon and Ben Nevis in our own country, and in both cases there is the prospect of sufficient water power being available close at hand for working the lines if thought advisable. The financial question of the cheapest method of operation is not, however, so easily answered, and it is quite possible that the steam locomotives now employed on the Snowdon line might prove more economical on the whole than electric motorcars. The decision in each case turns on the relation between average cost of fuel and the interest with amortisation of the capital outlay upon an electric generating station and plant. In Switzerland the cost of utilising water power is not usually at all excessive, whilst briquettes are 30s. a ton in Geneva.

The proper or most suitable type of locomotive or motorcar to adopt on an electric rack line involves a subject important enough to require consideration in a separate article, and the writer hopes to deal with the matter in due course at greater length than would at any rate be now permissible. It will be sufficient here to differentiate the motive elements of rack-railway trains into two great classes, according as the lines themselves are of the "sightseeing" or "tourist" order, being merely of short length running to the top of a height; or form part of a "through" line, being then a section or branch of an important thoroughfare. In the former case, although the grades are usually much steeper (ranging up to 25 or 30 per cent.) the loads are not very great, one or two cars for 50 passengers or so being practically all the train required. The motor output is not, therefore, often higher than 100 h.p. to 150 h.p., and motors with gear, etc., to this extent can be fitted up compactly enough below the framing or between the trucks of an ordinary passenger

Digitized by Google

car. Moreover, the deadweight of motive element is not very great, nor yet the total train weight, and therefore no particular advantage results from using the adhesion wheels for driving purposes as well as the rack pinions. Finally, each line being practically self-contained it may be wholly equipped with the rack, and thus offer no difficulties in the way of shunting or making-up trains.

Very different conditions are found to rule with the second class of rack lines. The train weights dealt with are much larger, as they form sections of main-line service, and the motive horse-powers run up to 400 and 500, although the grades usually are much less, ranging, say, from 1 in 25 to 1 in 8. In such cases it is absolutely necessary to build special electric locomotives which are fitted not only with powerful motors working the rack pinions, but have also other motors driving the adhesion wheels (preferably coupled together), so as to take full advantage of the locomotive weight and relieve the rack mechanism at least to that extent. Obviously the adhesion wheel motors are of great service in shunting and marshalling the trains when off the rack section. There are many points of great interest in the development of such locomotives, but, as already stated, they must be left for full consideration at another time.

Of this second class of line may be mentioned two typical instances from the writer's experience within the past two years, being called upon in both cases to give provisional estimates, etc., for their equipment. The first of these has a total length of 6·62 miles, with an average gradient of 1 in 22. The train loads to be hauled average 150 tons, at a speed of from six to ten miles per hour. Allowing a weight of 50 tons for the locomotive, an output of at least 675 h.p. would be required to pull the gross load of 200 tons at the higher speed; and no little care is necessary in scheming out the best method of splitting up this output amongst the various adhesion and rack motors.

The second line has points of still greater interest, seeing that it is mostly in tunnel and of much steeper grade, averaging 1 in 8. The train loads are smaller, not exceeding 70 or 80 tons, but owing to the steep grade, locomotives of almost as powerful a type would be required, weighing certainly from 30 tons upwards. At a speed of six miles an hour an output of 600 h.p. would be required for gross train loads of 120 tons on this incline.

The type of locomotive suggested for this purpose comprised two bogie trucks fitted with coupled wheels and motors for adhesion driving, carrying a centre framework for the rack motors and gear. In both cases intermediate spur gear was proposed, partly on account of the low train speed and comparatively small adhesion motor output, whilst its employment for the rack motors secures a more convenient framing. Moreover, the rack pinions themselves are merely spur gears with staggered-teeth, so that in any case the large motors would work through gearing. The use of spur gear for powerful electric locomotives would seem to run counter to good practice, as carried out on the Liverpool Overhead and South London Railways, where direct driving is employed; but that it has undoubted advantages is shown by its adoption throughout the series of large electric locomotives just designed by the Baldwin-Westinghouse combination.

WATER-POWER ELECTRIC PLANTS IN THE UNITED STATES.*

BY BUSHROD C. WASHINGTON, JUN.

For ages man has sought to overcome the vast powers of nature and so control them that they do his bidding. Human genius has gained this contest, and on the eve of the twentieth century an enlightened world gazes in wonder and admiration while Americans harness the power of their greatest rivers, convert this power into electricity and transmit it many miles to manufacturing centres.

The first application of water as a power for driving mechanical devices is supposed to have been attempted in Rome, about the time of Augustus, and during the succeeding centuries various machines have been originated for the utilisation of water power, and recent years have witnessed most rapid and wonderful progress in their development. The old waterwheels of various types gave way to turbine wheels for ordinary heads of water, and to wheels of the Pelton type for extraordinary heads. The users of water-wheels are too familiar with these two types of wheels just mentioned for me to attempt to describe them here.

The first transmission of electrical power for industrial purposes was accomplished in the year 1878, at Sermaize, not very far distant from Paris, France. The dynamos in this instance were driven by steam-engines. The application of water power for driving dynamos followed shortly after this demonstration of the practicability of the transmission of power by electricity.

Engineers bent their energies toward the development of the best machines for obtaining the largest percentage of the power at hand, and transmitting it with the smallest loss and at a reasonable cost. The result of their deep thoughts and long, tedious, and costly experiments is the utilisation of thousands of horse-power that had been wasted daily, and the building up of great manufacturing centres. There are to-day at least 300 places in the United States where water power is used for driving dynamos, and the resulting electrical energy used for light and power.

By corresponding with the manufacturers of waterwheels and electrical machinery a fairly complete list of the places in the United States where waterwheels are used for driving dynamos has been obtained, and to the electricians of these electric plants a letter was written asking them to answer certain questions embodied in a circular enclosed with the letter. They responded quite promptly, and the result is, the following questions regarding their plants have been satisfactorily answered—viz.: The types of turbines; sizes of wheels; head and fall of water; horse-power of each size wheel under this head; whether wheels are operated individually or geared together; type of governor on water-wheel; types of dynamos—arc, incandescent, or railway; dynamos driven from common shaft or independently; number arc and incandescent lamps; capacity, voltage, and amperes of incandescent and railway generators. Is there any steam plant? Are the steam and water plants coupled electrically or mechanically? Is the water power reliable the year round? Are storage batteries in use, and how? Number of miles of electric road operated.

A few declined to answer certain questions, but the majority cheerfully filled out the blanks and returned them to me; in many cases they added much useful information.

Nearly 40 per cent. of the water-power electric plants are situated in the New England States. This is accounted for in several ways: The presence of water power and absence of coal in their geological structure, the thickly-settled condition of these States, and the innate, inventive genius and business principles of the people. Then, too, their proximity to the educational and business centres of the country is an important factor not to be overlooked. Over 65 per cent. of all these plants have less than 20ft. head of water; and when we consider how many places there are having this fall or greater, it is certainly astonishing that this power is allowed to run to waste. A great many mills and factories supply their own light, and also furnish light and power to villages in which they may be situated, and even to villages at a distances.

Only a small number of plants operate the waterwheels individually, and the majority of this small number have the wheels so arranged that they can be geared together. A favourite way of developing power is by using horizontal turbines arranged in pairs. In many cases where horizontal turbines and Pelton wheels are used, the waterwheel and armature of the dynamos are on the same shaft. About 70 per cent. of the dynamos driven by waterwheels are driven from a common shaft, clearly demonstrating that this is the better method of utilising the power.

A little more than half of these plants have additional steam power. There are several reasons for this. First, the water power is not sufficient to fully meet the requirements; second, the water power is not reliable all the year round; and third, as a duplicate system in case of accident. The fact that many plants have additional steam power, and have not stated what proportion of the work is accomplished by water and steam power respectively, makes it rather a

*Abstracted from the *Electrical World*, New York.

Digitized by Google

difficult problem to fix the amount of work chargeable to water power alone. The reader can solve a great deal of this problem by noting the work done by the plants using no additional steam power. He will find that over 3,000 arc and 100,000 incandescent lamps and 82 miles of electric railway are operated by the water-power plants alone.

Of the 124 plants under discussion, 56 use waterwheel governors and 68 do not. Of the 26 plants operating electric railways, 19 use a waterwheel governor, five do not, and two have not stated whether or not they use such a device. The fact that so many plants do not use a waterwheel governor is almost conclusive evidence that they have a very steady power, and that the dynamos are not subjected to rapid fluctuations in their load. On the other hand, where exactly opposite conditions exist, as in cases where the power is used for street railways, a quick and reliable governor is a necessity, especially where the railway has many grades and several cars are likely to ascend a grade at the same time.

The utilisation of water power for developing electricity has become a great industry in this and other countries, and the leading manufacturers of waterwheels and electrical machinery are devoting a great deal of their time and energy to the development of special machinery for this particular field.

There are a large number of very large electric plants operated by water power, and these have been fully described in the catalogues of the manufacturers who designed and built the waterwheels and dynamos used in their construction and equipment, and also in the columns of many of the best technical journals.

The installation so successfully carried out at Virginia City, Nev., however, is worthy of especial mention. A dynamo chamber, 50ft. long, 25ft. wide, and 12ft. high, was excavated out of solid porphyry at the 1,650ft. level of the Chollar Mine. The water is brought down the shaft in wrought-iron pipes, these are united at the bottom into one single pipe, from which six 6in. pipes run to the nozzle of the waterwheels provided to drive the large dynamos. Under 1,680ft. head, 800 h.p. is developed.

The use of water for generating electricity has almost revolutionised the important industry of mining. Where no large streams are available, small streams are piped together and carried down the mountain until a great head is obtained; here the electric power plant is located and the power transmitted by electricity to the mine and used for lighting it, and driving the stamp mills and hoisting machinery. In places where the location of the water power is unsuitable for a manufacturing site, the power is developed at the falls and transmitted to the point where it is required.

The large manufacturers of waterwheels and electrical machinery are always willing to aid in the development of water power by cheerfully answering questions relating to the subject, and, if need be, will send on skilled engineers to examine carefully the location of the water power and make a full report upon the result of their findings.

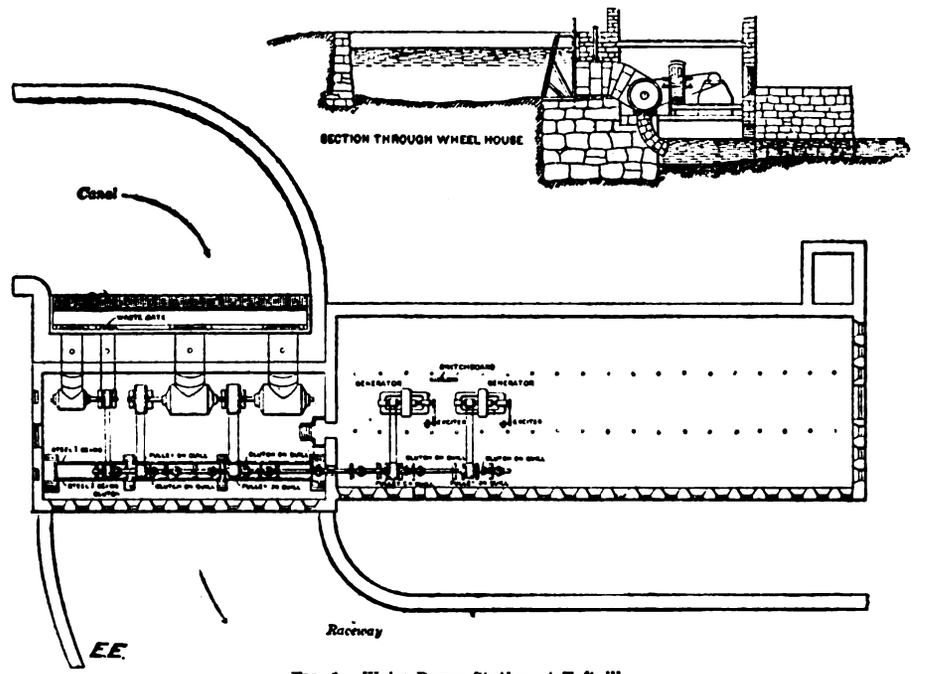

FIG. 1.—Water-Power Station at Taftville.

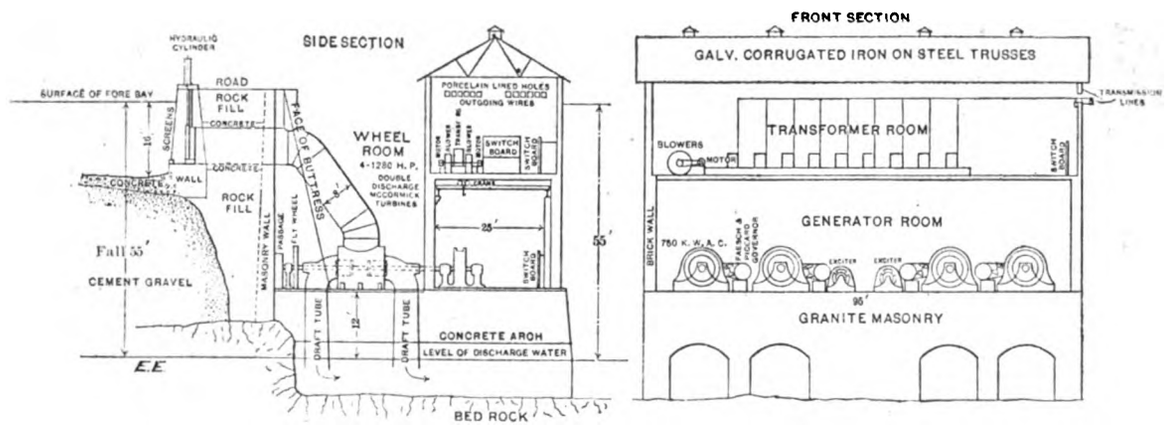

FIG. 2.—Arrangement of Sacramento Plant.

There is a very complete report on the water power of the United States in the Tenth Census report. It shows that there are hundreds of places where there is a good water power. These can be developed easily and made to pay a handsome dividend on the cost of development.

Fig. 1 is a sectional view of the water-power electric generating plant installed at Taftville, Conn. The General Electric three-phase system is here used, and the power transmitted from Baltic to Taftville, a distance of 4½ miles. Three turbines, supplied by the P. C. Holmes Company, Gardiner, Me., work under a head of 22ft.; two of the turbines develop 800 h.p. each at 157 revolutions, and

Digitized by Google

the third 300 h.p. at 244 revolutions per minute. The belts pass obliquely upward to the pulleys on the line shaft, and the turbines are kept at speed by Schenck electric governors In the dynamo-room are two 250-kilowatt General Electric three-phase generators, delivering current to the line at 2,500 volts and running at 600 revolutions per minute. Part of the electric power thus generated is used to operate at Taftville one of the largest cotton mills in this country, the remaining power being used by the Norwich, Conn., street railway.

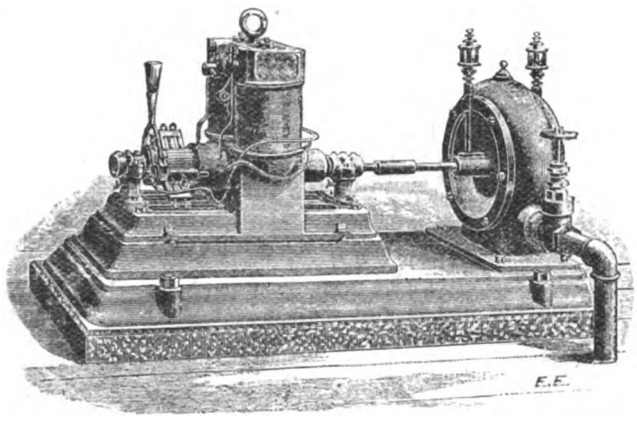

FIG. 3.—Pelton Motors Coupled direct to a Dynamo.

A plant having somewhat similar functions to the above is now being installed by the Bridge Mill Power Company, at Pawtucket, R. I. This will be of about 1,500 h.p., and will generate current for operating a street railway, for electric lighting, and for power purposes. There are five pairs of McCormick 33in. wheels, made by the Rodney Hunt Machine Company, of Orange, Mass.; these will be set 10 wheels together, in steel cylinder cases, 10ft. in diameter.

The water right is the last on the Blackstone River. The fall is about 24ft. After the river passes the dam it becomes almost immediately navigable. The power station is built upon a solid rock foundation, which has been blasted out for the purpose. The situation is exactly opposite the Goff

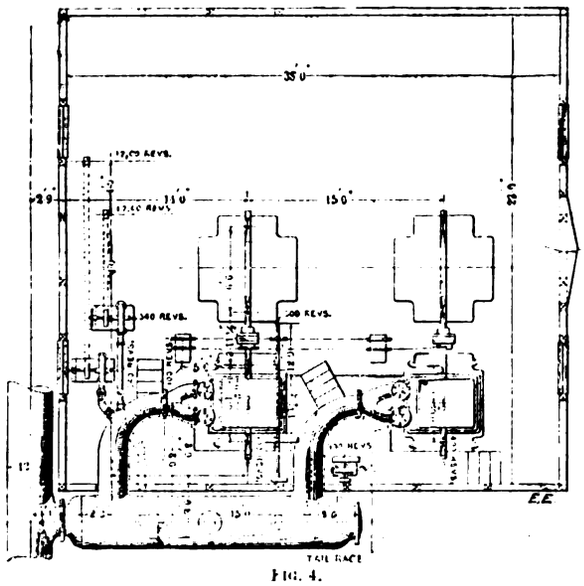

FIG. 4.

Braid Mills on the right-hand side of the river. The water enters a large brick tube and from that separates into the various penstocks for the turbines. A 500-volt direct current will probably be used.

Fig. 2 shows the arrangement of the plant of the Sacramento (Cal.) Electric Power and Light Company. There are four pairs of McCormick horizontal shaft turbine wheels supplied by the S. Morgan-Smith Company, of York, Pa., and located at Folsom. The governors are of the Faesch Piccard type, supplemented by heavy flywheels on the turbine shaft. Each pair of wheels has a capacity of 1,260 h p. at 300 revolutions per minute, and are operated under a head of 55ft. The plant also includes two special horizontal wheels for the exciters. The generators are four in number, of the General Electric three-phase alternating-current type, and furnish current at 800 volts potential. The armature shafts are direct connected to the wheel shafts by means of flexible couplings. Each generator is of 1,000 h.p., and all are located on the first floor of the building, 16ft. above the water in the tail race. In the second storey of the power-house and directly over the dynamo room are sub-station step-up transformers, in which the E.M.F. is raised to 11,000 volts for transmission from the Folsom plant to the Sacramento transformer sub-station, a distance of 22 miles. At the sub-station the voltage will be stepped down to 125, 250, 500, 1,000, and 2,000 volts respectively for lighting and motor circuits. In this station are three 300-h.p. three-phase synchronous motors directly connected to a line shaft and driving 500-volt continuous-current railway generators and a number of arc machines. At a recent test of these wheels, when a load of 800 h.p. was suddenly thrown off each pair, the governors regulated the speed of the wheels to within 3 per cent. of normal. When 25 per cent. of the load was thrown off suddenly, the governor regulated within $1\frac{3}{4}$ per cent. At present between 4,000 h.p. and 5,000 h.p. are being transmitted. The plant has been

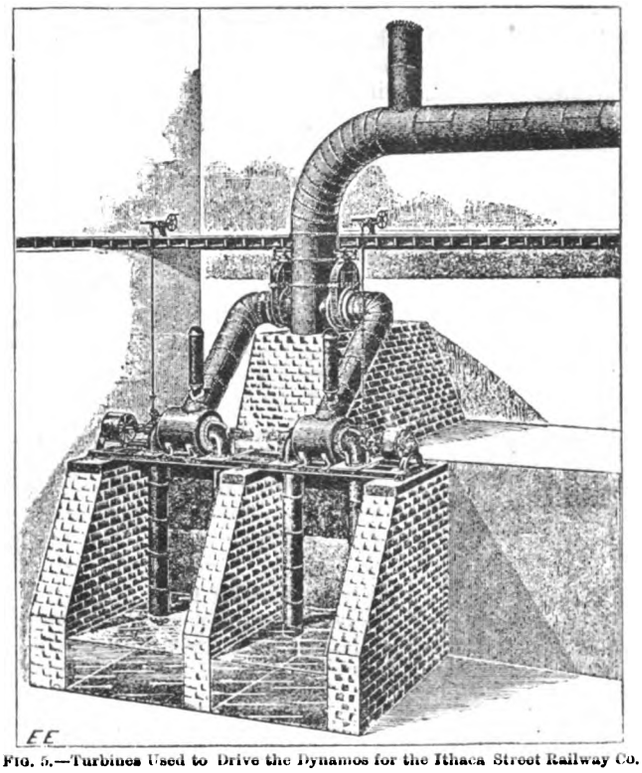

FIG. 5.—Turbines Used to Drive the Dynamos for the Ithaca Street Railway Co.

running steadily night and day since August of last year, and has proven most profitable and satisfactory in operation. All of the street-car lines of Sacramento are now run by electric power furnished by this plant.

Fig. 3 shows a Pelton motor connected direct to the shaft of a dynamo with an insulated coupling, both wheel and dynamo being mounted on a cast-iron bed-plate. This form of water motor is particularly adopted for very high heads. The motor consists merely of buckets attached to the rim of a wheel; the water is discharged into the buckets from one or more nozzles, the impulse thus imparted revolving the wheel at a rate depending upon the head. With high heads such motors can be direct connected to the dynamo, as in the case illustrated

Fig. 4 illustrates one of two pairs of Pelton wheels made for the Nevada County (Cal.) power station. The power here generated is to be transmitted to the various mines in the vicinity of Grass Valley and Nevada City, located within a radius of seven miles, and is intended for operating mills, hoists, pumps, etc. It is also intended to run a railway between towns above named. The plant is located on the South Yuba River, the flume having been arranged to carry sufficient water to increase the plant to 2,500 h.p. The wheels are of 500 h.p. capacity each, and are run under a head of 206ft. at 400 revolutions They are direct connected to two Stanley alternating-current generators of the same capacity Two separate wheels are provided for the exciters,

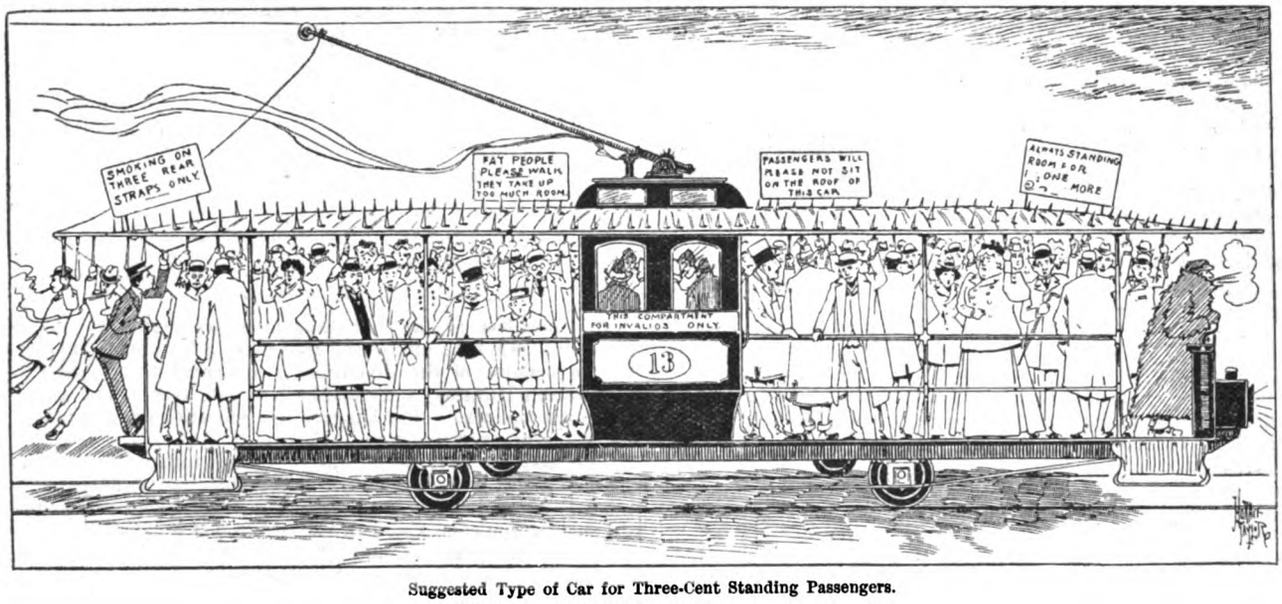
Digitized by Google

and Pelton differential governors afford the necessary regulation.

In Fig. 5 is illustrated the disposition of the turbines of the Ithaca Street Railway Company, Itchaca, N. Y. There are two 30in. horizontal wheels made by the Dayton Globe Iron-works, of Dayton, O., which operate under a 90ft. head. Each pair of wheels develops 400 effective horse-power, one furnishing power for the electric street railway and the other running electric lighting dynamos. The wheels are placed 20ft. above tail water and are supplied by a 60in. feed flume, which extends 550ft. up the stream from the power station. The generating plant was built to be run by water power when sufficient water can be obtained and a steam plant installed to assist at other times. There are two General Electric street railway generators and one alternator, one Brush alternator, two 30-light Brush arc machines, one 65-light Brush arc machine, and one 50-light Thomson-Houston arc machine The driving power is all connected to the same line of shafting to which the electrical machinery is belted.

THREE-CENT FARE FOR STANDERS.

The cartoon herewith, and for which we are indebted to the Chicago *Times-Herald*, suggests what might come if the threatened ordinance in that city should ever pass—which it will not. The ordinance calls for a three-cent fare for all passengers who are not seated, and the illustration pictures the type of car which would be needed to fill the bill.



SMOKING ON THREE REAR STRAPS ONLY
FAT PEOPLE PLEASE WALK THEY TAKE UP TOO MUCH ROOM
PASSENGERS WILL PLEASE NOT SIT ON THE ROOF OF THIS CAR
ALMOST STANDING ROOM FOR ONE MORE

Suggested Type of Car for Three-Cent Standing Passengers.

THE GARNESDON PRIMARY BATTERY BOOM.

BY J. H. C. B.

(Author of "How Garnesdon Got Electricity," "Mr. Molesby's Mysterious Motor," "Peculiarities of the Electrical Profession," etc.)

When the Garnesdon world had finally settled down to an appreciation of the fact that electricity *had* come into it, and was really to be depended on, the demand for the new light became a factor of encouragement to the Electricity Supply Company and a thorn in the side of the gasworks officials. To keep pace with this demand, a mushroom growth of "electricians," "electrical engineers," and "electrical contractors" was brought about, chiefly recruited from the local plumbers, carpenters, and gasfitters, with a leaven of City and Guilds' graduates.

Oliver Buncombe first began to take an interest in Garnesdon, apart from his occasional comparisons of "price per unit generated," when he heard from a relative living near there that the town was in want of some good wiremen. The relative stated that the "practical men" who fitted up houses for electrical illumination were charging excessively high prices, and that much of the installation work was based upon an evident belief in the insulating properties of moisture, and conceived with original ideas regarding the current capacity of copper wire.

The hint was sufficient for Buncombe. Having spent most of his time either in the comfortless laboratory at Leonard-street or in the Patent Office library, he had no particular ties of a social character to break, wherefore he bade his parents *au revoir* and went to Garnesdon, strong in the hope of his relative's introductions, and determined to show what Thompsonian teaching could bring forth.

He had not long to wait. Scarcely had his modestly-worded circular letter been the rounds of the compulsory area, when his relative sent him the names of two people who wished their houses installed. Buncombe submitted an estimate based upon 30s. per light, and was agreeably surprised to find them accepted in both cases. He had done little odd bits of wiring at times, and learnt from books and the anecdotal experiences of friends in the trade, but he had never had a 25-light job before, and in his calmer moments he felt a trifle uneasy about the result. His education had been such that he could have designed a multiphase dynamo, or tested the "funniest thing" in cable faults with a greater amount of confidence than he had in his ability to get leads through ceilings, brick walls, and other ghastly obstructions which the legends of his friends had credited with defying braces, cold chisels, and the efforts of contorted and perspiring wiremen.

However, the Fates were kind, and the houses chiefly wainscotted, so Buncombe pulled through with the help of an out-of-work plumber, and by putting in good material and conscientious workmanship he got testimonials which stood him in good stead in obtaining further orders.

One eventful day he had to work overtime on an installation that was wanted particularly by a certain date—the twenty-first birthday of the daughter of the house—when an "At Home" was being given by the young lady's mother, Mrs. Bright. Buncombe had been on the job all day from early morn to dewy eve, and was by no means confident of having his work finished in time for the following evening's festivities. This uncomfortable feeling was increased by the fact of his man's pension falling due on the previous day, and consequently he had come along too drunk to do a stroke, and would probably be worse than useless until he had got rid of his superfluous cash in company with his old comrades-in-arms; so Buncombe gave him the temporary sack.

By night Buncombe had got everything put up—primitively, it is true—and after turning all the branch switches on he closed the main switch and went through the house to admire the effect. On entering the drawing-room, however, he found all in darkness, and then he remembered that his wireman had started work in the room that morning before being told to go. He went to the door switch, and, unscrewing the cover, saw by the light of his match a blackened base and the two ends of a fuse. This explained the matter; the fuse put in had been too small, and as a natural consequence had burnt out on the current coming on.

Buncombe felt much annoyed at the man's stupidity, and recollecting that the rest of the fuse wire was stowed away at the bottom of his tool-chest, the effect upon his already over-anxious mind was such that he said what he thought about the culprit in a spiteful undertone and with little circumlocution or delicacy of expression. It was in the middle of a particularly *recherché* passage that a slight movement in the room caught his ear and, staying his tongue in its five-finger exercise, he looked

Digitized by Google

around and saw that Miss Bright was lying on the couch with both hands to her ears and a shocked expression on her face. She was looking directly at him, so Buncombe, with the flame of the match approaching perilously near to his finger tips, lowered his head in abject sorrow, and, in his most contrite manner, begged her pardon, mentioning that he did not know anyone was in the room.

"Is that any reason why a man should so degrade himself?" asked Miss Bright, severely, taking her hands from her ears, and sitting up.

"None at all," faltered the unhappy Buncombe. "I can only say that it shall never occur again."

The very next thing he said, however, quite gave his assertion the lie, for the match had burnt under this thumb-nail, and the sudden agony bereft him of what remnant of reason he had left.

Before the echoes of the semi-scriptural exclamation died away, Miss Bright had hurriedly sprung to her feet and brushed past him out of the room, and Buncombe, when he was sufficiently recovered to do justice to the occasion, shut the door and had a soul-satisfying five minutes with the best authors, after which, feeling better—as men do when they have relieved themselves of an overload of spontaneously generated profanity—he wedged a penny between the fuse terminals, and had the satisfaction of seeing the lamps become incandescent.

Early the next morning he got to work, and was putting the finishing touches to the hall fittings, when dainty footsteps on the stairs made him instinctively aware that the shocked fair one of the previous night was coming down to breakfast, and the spirit moved him to wish her "Good morning, and many happy returns of the day."

"I hope you mean none of last night," said the girl, hitting the nail on the head, and there being no one about she dropped her voice, and said more seriously, "It was very sad to hear such a young man speak so irreverently."

Buncombe could not help smiling; he was not used to being called a young man by anyone under middle age.

"And I'm sorry to find that you treat the matter so lightly," she continued, and was moving away with an air of offended dignity, when Buncombe recovered his gravity and the sense of the situation, and explained that he had meant no irreverence, but had been very much upset the night before to find that the electric light might not be ready in time for the "At home."

"Will it be quite ready now?" asked Miss Bright, when he had finished his apologia.

"Yes, unless my man has done any more bungling that I have not discovered."

"In which case I hope you will control yourself rather better than you did last evening." And she disappeared through the morning-room door.

Buncombe managed to get through his work that day without serious mishap, though he did try to connect lamps to acorn pushes, and attempted to use screw-drivers on hexagons occasionally. This, as an effect of overproof penitence, was to be excused, and he divided his leisure thoughts between comparing himself to loathly things and dwelling on the inflections of her voice and grace of manner. And in course of thought, his personal conceit being brought to bear upon the subject, it struck him that he had been a very lucky fellow in getting off so easily, and that perhaps, on the whole, he had done a very good thing for himself. The girl's face was not strictly beautiful, judged from Roman or Grecian or Etruscan vase standpoints, but it was a clever face and interesting, while her manner charmed him. With almost a woman's instinct he found himself surveying his working clothes with a degree of false shame that he was unused to. This sign alone would have told an observer (in terms as clear as a trade consulting electrical engineer specifies patented machinery for public tender) that Buncombe had found his divinity. Whether he was successful in obtaining his contract for maintenance of same it is the purpose of this history to discover.

* * * * * *

Several moons had measured their photometric qualities against the Garnesdon arc lamps since Oliver Buncombe first met Frances Bright, and having discovered that his relative knew the Bright family, his acquaintanceship with her had gradually ripened since the first inauspicious *rencontre*, until now he was her greatest masculine friend. This coveted distinction, however, was no sinecure, there being several competitors ready to undercut him, and the favourite of the second string was also in the electrical line, being a manufacturer of small dynamos, motors, batteries, and general fittings, in addition to which he did installation work.

Thus Oliver Buncombe and he, David Chilcote-Huntley, A.I.E.E., were often co-tenderers for contracts, but the principal cause of rivalry existed in another and, it may be added, a tenderer direction.

And so it came to pass that when Buncombe one day read a certain paragraph in the "local rag" he was sore dismayed, for Miss Bright had a weakness for genius, and the most flattering thing she could tell anyone was, "How clever you are!" Huntley had considerably risen in her esteem since he had added the slightly fanciful initials "A.M.I.E.E." to his name, and now Buncombe feared for the worst if the paragraph was bolted to the concrete foundations of fact.

The paragraph ran as follows:

REVOLUTION IN ELECTRICAL SCIENCE!—*Garnesdon Leads the Van of Progress*!!—It has been our lot during this newspaper's existence to chronicle many wonderful local occurrences, but the subject upon which we now write is, we feel sure, destined to overshadow all previous happenings in our pretty little town, and will eventually make Garnesdon an honoured name in the history of electrical invention. It may not be generally known, owing to the modesty of the gentleman himself, that our esteemed fellow-townsman, Mr. D. Chilcote-Huntley, A.M.I.E.E., has been making elaborate experiments during the last few years on primary batteries. These experiments have now culminated in a discovery which is destined to *revolutionise electrical science*!! We do not make these statements rashly, for we have been favoured with a special invitation to test and report upon the result of Mr. Chilcote-Huntley's labours. At the time of our visit we found him deeply engaged in abstruse calculations at his desk, surrounded by works upon electricity, chemistry, etc., and after showing us passages in these, declaring that two volts was the utmost current obtainable from a single battery, he connected the cords of a measuring instrument to one of his own special batteries, and proved that the electric motive force moved at the rate of three volts per second. The instrument we were assured was correct, and Mr. Huntley showed us a report from an eminent consulting electrician to whom he had sent one of his batteries for testing purposes, which stated that "the cell maintains a fairly constant E.N.F. of three volts, with an internal resistance of 2·10364 ohms." The battery has, of course, a commercial as well as a scientific side, and we beg to draw our readers' attentions to our advertising columns for further particulars.

With a sinking heart, that even the light side of newspaper science could not entirely arrest, Buncombe scanned the advertisement pages, when the following caught his eye:

THE MOST POWERFUL PRIMARY BATTERY IN THE WORLD.

A Three-Volt Cell!!!

Can charge accumulators at small cost. Is suitable for all kinds of work. No need for machinery for country-house plants. No dirt, no smells, no oil. Maintenance guaranteed smaller than any other make. Can always be recharged and does not deteriorate. Send trade card for price list and full particulars to

D. CHILCOTE-HUNTLEY AND CO., 13, Chester-road, Garnesdon.

Works: Rake-lane, Garnesdon.

Agents Wanted.

It is needless to say that Buncombe felt very sick; he felt sicker still when he discovered that most of his clients, attracted by the glamour of the invention, transferred their custom to the Maison-Huntley, and that the bulk of fresh trade went in that direction also. But the sickliest sensations were provoked by the green-eyed monster.

This may not have been quite necessary, but, to do Buncombe justice, it was perfectly natural under the circumstances. Few men have philosophy and sense of discernment enough to distinguish between a woman's admiration of an abstract quality and the deeper feeling, and the more blind in this respect are they who play the game. So that when Buncombe had to listen to his divinity's eulogies of the battery inventor; when he noticed the glances of respectful admiration that she bestowed upon his rival; and last, but not least, when his business slackened to the very verge of holiday-making, while the other man was working overtime regularly, he began to consider the advisability of inventing something if only in self-defence.

What it was to be Buncombe himself did not know. Being no chemist, he at first disdained the idea of batteries and processes, and dwelt upon the nobler flights of perfecting either dynamos, transformers, meters, etc., or if the worst came to the worst he would invent a switch. With this end in view he sought his friend Barker, the electrician at the electricity works, and in course of conversation endeavoured to discover what portion of the plant wanted perfecting most.

Barker, however, appeared quite satisfied with the original design of the station machinery and apparatus, and could only suggest improving the greasers and improvers into habits of discipline, sobriety, and ordinary carefulness, for it was well known that Holloway, the engineer, had a hot handful of a staff.

"Nothing on the mains even that wants furbishing up?" enquired Buncombe. "No fancy switching arrangements for regulating varying loads or connecting street arcs?"

But Barker was confident that everything was in satisfactory order, and it is improbable that he would have given any intimation otherwise in any case to a fellow electrician, for palpable reasons.

So Buncombe returned to his establishment with the fixed resolve of clutching at the straw of switch invention. But the possibilities of distinction in this branch of discovery soon disappeared when he surveyed his varied stock of *interrupteurs*. As he observed in a moment of lax-tongued despair, "Every blooming way of doing every blooming thing is already too blooming well done." That night he dreamed of inventing a

Digitized by Google

perpetual polyphase motor, with fields excited by the earth's magnetism, and, on waking, went to work with fierce energy to devise the best means of applying terrestrial magnetic lines to dynamic machinery.

Buncombe has not yet perfected his arrangements in this department of applied science.

* * * * * *

Oliver Buncombe never knew exactly how or when the magnificent idea occurred to him, but to this hour he attributes its happy advent to the special interposition of Providence. This view is perhaps somewhat weakened by the fact that Buncombe, in his installation work at least, had never trusted much to Providence, and therefore it is fair to assume that it would hardly be likely to shower favours upon him. However, the idea came, it took root, and finally it blossomed, and the invention of a perfectly astounding primary battery—once the despised and rejected road to fame—was the outcome of the thought.

And so it came to pass that the following article in the *Garnesdon Observer* shook the electrical section of the town to its base-plates, and the local "A.M.I.E.E." knit his learned brow with righteous wrath and astonishment when his mind had grasped the fact that his rival in love and competitor in trade had trumped his ace:

GARNESDON MOUNTS THE LADDER OF FAME ON THE WINGS OF PRIMARY BATTERIES.

Yet another local Edison!

When we noted in our issue of the 23rd ultimo (copies of which can still be obtained) that an invention of the first importance in the electrical world was due to the ingenuity of our fellow-townsman, Mr. D. Chilcote-Huntley, A.M.I.E.E., we little thought that within the boundaries of our town another mind was occupied in the same work of making two blades of grass grow where but one had grown before, and that the millennium of electrical service was being hastened through the same channel of discovery.

To be brief, the latest inventor among us is Mr. Oliver Buncombe, Cert. Honours, Finsbury Technical College, who since he came here, barely six months ago, has been responsible for the efficient fitting up for the electric light of a great many of the better-class houses in Garnesdon. When, in response to his invitation, we called upon Mr. Buncombe, he told us that his experiments in the direction of a perfect electrolite had been the dream of his life, but that until very recently, spurred on perhaps by the success of his friend Mr. Huntley, he had almost given up hopes of realising this ambition. At last, however, he has succeeded in producing a battery which gives no less than 5·47 volts with an internal resistance of but ·65 ohm. This, we need hardly say, out-Herods himself in the shape of Mr. Huntley's remarkable discovery.

It might be reasonably imagined that this result would reach the limit of electric battery power, but Mr. Buncombe is sanguine of his ability to still further improve in this direction, and therefore, while allowing every facility for testing his cells, they will not be manufactured commercially until he is sure of no further improvement being possible in the electrolite.

We may say that we have seen the battery tested, and are satisfied of the *bonâ fides* of these statements, and we shall chronicle with interest further developments of this wonderful invention.

It was now Huntley's turn to become sick, for he, too, had observed the little weakness for genius in Miss Bright's mind, and he had also been misinterpreting the

"Becks and nods and wreathéd smiles";

for such was the natural charm of her manner that an impressionable man might be forgiven for taking things rather for granted. He had noticed, also, the additional interest she had favoured him with since his own invention appeared in print, and though he would not confess openly to himself that Buncombe's invention would make any difference to him in that quarter, he instinctively felt that it would be very much more satisfactory for himself if Buncombe and Buncombe's battery were in permanent residence in Hades.

As for Buncombe himself, he would hardly have changed places with the P.F.R.S., so consistently joyful did he feel. Not altogether on account of the intrinsic value of his cell, for he had reasons for supposing that, whatever its virtues from a scientific point of view, it would hardly be the commercial success that the "local rag" anticipated. Still, it would be the means of restoring his prestige in the eyes of his inamorata, and it would bring grist to his mill. It was well known that on account of its high price the Huntley cell did not sell well, but that its fame brought its inventor customers for other goods. In like manner Buncombe hoped to reap success, and already looked forward to an extension of premises and an augmentation of staff.

Then the question arose in his mind as to what he should call the cell. Should it deliver his own name to an unending immortality as the "Buncombe cell," or should it receive a classical or fancy name, emphasising its power and long life, such as the "Sandow" or "Methusaleh"? The former course Buncombe's modesty protested against, and the latter seemed more fitting for incandescent lamp designation or gas-engine nomenclature. Or, since he might have to form a company to exploit it and furnish capital for an enlarged sphere of operations, would it not be best to follow the prevailing fashion in battery-naming and call it by the initials of the company's title, such as the G(arnesdon) P(rimary) B(attery)? Eventually, however, he decided in the fulness of his heart, and in utter defiance of all the canons of electrical battery appellation, to call the cell the "Frances"; and with regard to the prospective company that would be formed on the strength of its good name, he mentally drew up an advertisement for the electrical magazines replete with short, crisp, competitor-defying phrases in various sizes of block lettering, with illustrations and text fearfully and wonderfully arranged to catch the eye, and he finally dropped off to sleep that night endeavouring to decide on a suitable telegraphic address that would indicate forcibly the supreme worth of the company's work and goods, and yet be a word easy of remembrance by the busy contractor.

And all next day he thought of the possibilities the thing opened up, the attainment of A.I.E.E., and the gradual transition to M.I.E.E., the suite of electrically-lit offices in that hotbed of electrical engineering, Westminster, the admiring reception that should be accorded to his paper delivered before *the* Institution on "Some Recent Abnormal Developments in Electrical Primary Cells," and the charms of the discussion that should follow, in which every professor present would compliment him fulsomely upon his invention and would each casually mention his own previous discovery of its principles. The latter reflections, however, seemed to amuse Buncombe more than was absolutely necessary, and he enjoyed the effects of his imagination still more when contemplating the technical magazines' probable reports of his paper, with white discharge diagrams printed on a black ground, which would make a fearful mess on the fingers of the readers of the *Electrical Laroo*, whose printers' ink took months to dry. And joyful visions of an earthly paradise replete with domestic bliss filled his mind, until in looking over his *Electrical Buccaneer* of the current week he found that part of the *Garnesdon Observer's* article relating to his cell had been reproduced, and that the following editorial comment was appended:

The above is submitted as a sample of provincial newspaperese. We hardly think it worth dealing with otherwise, as the veriest tyro in electrical knowledge will be aware of the absurdity of its statements, which is about on a par with its knowledge of technical spelling. What manner of man this Mr. Oliver Buncombe may be, who has inspired the guileless provincial editor with his abormal abilities, is a puzzle, inasmuch as he appears to have done a certain amount of installation work with credit. Whether he has deceived himself over this cell (or sell) more than the editor of the Garnesdon paper is not of our knowing, but we charitably hope, for the sake of Mr. Buncombe's reputation, that the figures given are misprints, and that the literary matter is the self-inspired drivel of the mechanical newspaper scribe.

Buncombe read this through without turning a hair. He might have expected it, so unconcerned was he over the sloshing of "his life's dream."

"Oho!" he murmured pleasantly; "so the press-clippings people have got hold of the *Observer*. I wonder what the other papers have to say about it"; and he went out and borrowed the other electrical magazines from different people, it not being fashionable to take in more than one of the technical papers at a time in the provinces, and they are not readily obtainable at bookshops or station bookstalls.

The *Electrical Laroo* was one gigantic advertisement of a newly-opened central station that week, with a description replete with adjectives of superior quality concerning every trivial detail of machinery in connection with the station, and what space it had to spare was occupied by correspondence upon one of its ably worked-up controversies, so that it had evidently no room for baiting such regular quarry as battery inventors.

The *Electric Ion* being somewhat empty on account of its universally interesting serial article by Roland Ditchwater having to be delayed that week, on account of the printers running out of Greek and Arabic type, had found room for a leaderette paragraph, which commenced with an aphorism, was interlarded with quotations, and concluded by appealing to the gallery with the statement that "Cells which depend upon special chemical processes for their successful working are, in more senses than one, *drugs* in the market."

Electricality also had a note at the end of its "Chatterbox" columns, which, after quoting from the *Observer*, said: "It is amusing to observe at what regular periods the primary battery inventor makes his preliminary flourish of trumpets through the untechnical Press, and how similarly ridiculous are the advantages claimed for each new type of cell. One source of comfort, however, for the perpetually threatened engine and dynamo manufacturers lies in the uniformity of nothingness to which these enterprises come. Whether or not the promoters of such absurd ventures are more fools than knaves is often a subject for conjecture with EXPECTRONG."

Fizzling did not mention the matter at all, and Buncombe surmised that it was sitting on the fence waiting to see what the *Buccaneer* and *Laroo* said, so that it could be sure of either taking an opposite view or could split hairs over the former's grammar and point out errors in the latter's classical quota-

Digitized by Google

tions, which were its chief functions in its capacity as court fool to the profession.

Buncombe had just finished reading these encouraging expressions of opinion, and was congratulating himself that Garnesdon as a whole was not likely to see them, when Mr. Huntley was announced. The two men eyed one another keenly while shaking hands, and the visitor said :

"There's a strange article in the *Observer* about a miraculous cell which it says you have invented. As you know, I am interested in that kind of thing, and I have called to see if there is any truth in the report."

"The account is perfectly true," replied Buncombe. "Of course, you will understand that I did not supply the high-falutin' part of it, or the execrable technicalities, any more than I presume you did in your cell's description ; but the figures are right enough, and that is the principal thing."

"Well, you'll excuse me, I hope," exclaimed Huntley, "but it seemed to me to be perfectly absurd—most awful rot, in fact, and I have not met anyone who knows anything about cells who believes a word in it.

"You are all welcome to your opinions. I hope to have a public demonstration shortly, and then you can see for yourselves. In the meantime, perhaps you would like to see the article in question ?"

Huntley jumped at the offer, but was not so pleased upon being told that he was not to touch the cell.

"You will understand that my process is so simple that, until I can protect it legally, I must be careful," Buncombe had said.

So Huntley passed his society affidavit not to do any undue investigating, and followed his host into the back room, where, illuminated by a dim, religious light from some dingy back yard windows, the bulky form of a glorified Leclanché-looking cell was apparent on a table. The testing instruments lay near, and some rival trade catalogues, with a broken carbon block or two, gave a realistic picture of an "electrical contractor's" lab.

Buncombe had the connections ready between his cell and the apparatus, and Huntley saw that the reading on the galvo. was over five volts by comparison with the standard cell deflection. Then Buncombe brought the Wheatstone into play, and showed the resistance to be the simple demi-ohm he claimed. Very little was said by both men ; the one keenly critical and noting every detail of the cell, the other seemingly absorbed in admiration of his own work, but never turning his back upon the visitor for a moment.

"Is there anything else I can show you ?" said Buncombe at last, noticing that Huntley was looking about the room as if in search of something.

"No, thanks," answered Huntley, bringing his eyes back with a jerk to the subject of conversation. "I suppose you would not care to lend me the cell for a day or two ? I think I have more facilities for experimenting than you seem to possess, and if I discover any improvements on it you can rest assured of your share in the profits."

"Much obliged," smiled Buncombe ; "but I guess I can finish the thing off now, after getting on so far with it," and he moved towards the door.

But Huntley did not take the hint. His eyes were again wandering over the room, and presently he said, in an absent-minded way :

"You haven't seen any of my cells yet, I suppose ?"

"No," answered Buncombe, playing with the handle of the door.

"Well, I wonder if you have gone on the same lines as myself," continued Huntley. "I hit on peroxide of lead in contact with platinum, having zinc and sulphuric acid outside the porous pot, and then I found lead would do just as well as platinum for the positive pole. This combination was successful enough to make me want to get more out of it, so I tried oxalic acid and obtained an E.M.F. of 2½ volts with an internal resistance of only half an ohm, and the voltage hardly dropped at all after two days' work !"

"Oh !" said Buncombe, feeling that all this was only intended to draw him into an exchange of confidences.

"Yes, 2½ volts right off the reel, and even then I was not satisfied ; but what do you think gave me the three volts I was after ?"

Buncombe scratched his head gracefully, in seeming meditation upon the question.

"Why, caustic potash," Huntley went on ; "only the resistance went up because another porous pot was used. And the price went up, too, unfortunately. Now, I wonder what you can sell your make at—the gross, I mean ?"

But Buncombe did not reciprocate, so Huntley, after unsuccessfully suggesting mutual refreshment (which among business men is the usual preliminary to making something out of one's guest), left the place with nothing satisfactory for his pains.

Buncombe went back to his lab., and investigated a window that Huntley had been scrutinising intently during his discourse. There was nothing very attractive about it, even if it had been a clean window, which it was not. It, however, opened directly into a blind alley leading from the main thoroughfare, and Buncombe noticed that the bolt was unfastened. He had put it under its clip, and then a thought struck him, and he unfastened it again. This was a strange thing to do, but some other actions of Buncombe's were more mysterious even than that.

He went to the bench, put his hand down into the cell and unscrewed some things at the bottom of the elements which looked suspiciously like terminal nuts, though why the cell should require electrical connections at the business ends of its electrodes will for ever remain an insoluble mystery. He then disconnected some attachments from the bottom of the cell, and carried it into his private office. Returning, he pulled a Daniell battery from under the bench to another part of the room, together with some rubber-covered wires that were now to be seen projecting through the bench, like dining-table lamp fittings.

After which he brought a glazed porcelain cell of the same size as the one he had taken away, and put in it elements of the same nature as contained in the original. To all appearance the cells were identical, and Buncombe filled the pot with insulating oil, which in the dim light completed the resemblance. His next step was to select one of his stock of transformers, which were used on the Garnesdon high-tension circuits, and to attach its low-tension terminals to the main switch of his establishment and the high-tension side to the poles of his mock battery, the latter's connecting wires leading from the direction of the testing instruments.

Then he went to bed, but not to sleep.

* * * * * *

The gas company's officials were as near chuckling with delight as ever they had been since the Garnesdon Electricity Supply Company, Limited, commenced operations, for an ill wind had blown that appeared likely to waft them a certain amount of good. That is to say, another death from electricity which had just occurred in the town would inspire people, they hoped, with distrust for the new illuminating power, which killed in a more mysterious and therefore less agreeable way than a materialistic gas explosion. And, as if to point the moral more suggestively, the victim this time was an eminent local electrician, who had gone out under circumstances which did him no credit.

The "local rag" explained the matter in six columns, but the leaderette upon the subject was more succinct and bears quoting here :

ANOTHER VICTIM TO ELECTRA.

Elsewhere we deal more particularly with the horrible fate of D. C. Huntley, of Chester-road, whose tragic end has caused widespread consternation and sympathy. Whether this latter feeling is altogether deserved remains to be dealt with at the inquest, but at present the evidence tends to show that the unfortunate man met his doom, not only through his own carelessness, but by his own criminality. It is not well to speak harshly of the dead, but facts are facts, and it is a newspaper's province to relate them. It will be remembered that deceased invented an electric battery, which was reported upon in these columns as the most powerful one of its kind, and a week or two later Mr. Buncombe also invented a battery which was much superior to the invention of the deceased. This would appear to have unhinged the latter's mind, for he was discovered in Mr. Buncombe's private laboratory early on Wednesday morning dead from contact with some apparatus that Mr. Buncombe had been testing with high-pressure currents. An open window had evidently been his mode of ingress, and it is easy to see that he came during the night to discover the secret components of the battery which had eclipsed his own. Mr. Buncombe, who was greatly shocked and grieved by the sad occurrence, states that the apparatus in question was roughly put up to determine the insulating properties of a certain kind of oil, and that the deceased must have mistaken it for the new cell, and putting his hands on the poles completed the electrical circuit, with the result that he received 2,000 volts through his body. This makes the third death in Garnesdon from electricity ; but it is as well to remember that all of them have been brought about by the worse than heedlessness of the unfortunates themselves.

On a certain day very early in the morning a quiet little wedding was celebrated at Garnesdon Parish Church, and the bridegroom was spoken of with respect as the busiest electrical contractor in the town, and the inventor of the wonderful "Frances" cell. The bride's christian name, singularly enough, was Frances also, and it is to be hoped that their wedded happiness will last until that period of revolution in the electrical industry when (*vide* the inventor's special circular) "the few final details of improvement having been decided upon and legally protected, the cell will be subjected to a public demonstration which will prove its immense superiority over any other type of cell for HIGH POTENTIAL, CONSTANT CURRENT, LOW RESISTANCE, MINIMUM OF ATTENTION, AND CHEAPNESS BOTH IN FIRST COST AND UPKEEP."

Naval.—The cruisers "Barham" and "Bellona," attached to the Channel Squadron, are to be paid off, so that each may have a thorough refit. Both will be fitted with complete sets of water-tube boilers, and also with new electric light machinery. Upon each nearly £30,000 is to be spent.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THE INSTITUTION BALANCE-SHEET.

The balance-sheet of the Institution of Electrical Engineers for the year ending December 31, 1895, was despatched to the members about a fortnight ago. As will be seen in another column, the presentation of the sheet for approval at the last meeting of the Institution was made the occasion of another display of the friction recently developed between a few members and the Council. As will be remembered by our readers, the annual meeting held last December was devoted to a debate as useless and nearly as personal as that of an average London vestry. Although the subject opened for discussion was one which could have been discussed to advantage, the whole evening was practically wasted, as no vote could be taken. Afterwards, the question was evidently not considered sufficiently practical by its originators to warrant calling a special meeting, as was suggested by the then president. The waste of time begun at this meeting was continued until the new president wisely curbed the verbosity of the debaters. Members had become so used to enlarging on their personal experiences, rather than giving useful conclusions from them, that most of the speakers exceeded the time limit, and many the patience of their hearers. On Thursday week the subject forming the bone of contention was one of the utmost importance to everyone present. We endorse the opinion of the mover of the amendment, that "an absolutely sound balance-sheet is the greatest security that the Institution could have for the safe transmission of its funds to future generations." The question as to whether the building fund was defrauded of ninety pounds due as interest is one on which the evidence of the three eminent accountants would have been worth hearing. If the building fund is looked upon as a reserve fund, the interest should certainly go to swell the general account, as has been done. The fact that this reserve fund is eventually intended to be used for building purposes is as yet unacknowledged, as far as we know, by charter or by articles of association. So, arguing from the usual practice of limited liability companies, this reserve fund stands at a constant figure, unless increments are added after a prosperous year's working. The other points raised were all points of detail which could be readily explained by anyone reading the accounts. The main facts of the case are these. We were assured that three eminent accountants and one eminent engineer had carefully examined the accounts, and had found them absolutely correct. This statement came on early in the evening, and we all waited for the "juice" promised by the speaker in an ill-judged letter to a contemporary. We certainly got a lot of illustrations as to the use of oyster beds, the cost of wall diagrams, and the unlimited time at the speaker's disposal; but we should much like to know if the real juice was not the wish to pass a vote of censure on the honorary treasurer? After posing as a martyr because the president objected to the time of some two hundred and fifty members being wasted, it was moved and seconded that the balance-sheet be referred back to the Council for amendment. The only useful point

Digitized by Google

brought out by the accountant in reply was that an increment in the value of the books, etc., was due to the gifts of various members. The vote then taken showed twenty-seven in favour of the amendment and seventeen against. In other words, out of two hundred and fifty members only forty-four cared enough about the subject to hold up their hands either way. This would hardly have been the case had the funds of the Institution been in peril. Of the composition of the majority, the less said the better. We would emphatically state that the want of detail in the accounts could have been clearly explained in five minutes, and that the course taken was in no wise justified by the evidence brought forward.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE REDUCTION OF LIGHT-LOAD LOSSES IN ALTERNATING STATIONS.

SIR,—Would not accumulators help us in such a station nearly as much as they have continuous-current stations? It appears to me that there would be no practical difficulty in applying them. Take an ordinary drum or ring wound armature, and at two points on the winding, 180deg. apart, take a connection to each of two rings. If the armature is then set revolving in a magnetic field by a continuous current passed through the windings and through the usual commutator, an alternating current will then be delivered on the rings having a period depending on the number of poles and on the number of revolutions per minute. For example, let the armature revolve in a four-pole field at a speed of 1,500 revolutions per minute; then if the continuous current supplied is at 100 volts, an alternating current will be delivered on the rings at a pressure of about 70 volts and having a 50 ⁓. In this case the rings will be connected to the armature windings at points 90deg. apart.

For the purpose of regulating the pressure developed on the continuous side of the machine when charging accumulators, the secondary of the alternating transformer which would be interposed between the rectifier and the 'bus bars would have a number of connections taken off to a segment switch in a similar manner to the terminal cells of an accumulator; the alternating volts supplied to the rectifier being thus varied, the pressure on the continuous side must necessarily also vary. The alternating transformer would also serve as a "step-up" when running the circuits off the cells, and in this case the segment switch would serve to roughly regulate the volts on the 'bus bars. The machine might be run up to synchronous speed when started on a nearly exhausted battery prior to switching-on the alternating current by suitably weakening the field, and the same method of regulating the speed would also serve as a "fine adjustment" of the 'bus-bar pressure when running the circuits off the battery. The same type of machine might be used for feeding electric tramways from alternating circuits.

Further, if in our four-pole machine we connect two other rings at 45deg. and 135deg. respectively, would not these rings deliver a current in quadrature to the other two rings at 0deg. and 90deg., and our single-phase current be thereby split up into a two-phase system?

There are obviously many possible applications for such a system, but it is needless to further encroach on your space to describe them in detail.—Yours, etc.,

GEO. T. PARDOE.

81, Harrow-road, W., March 30, 1896.

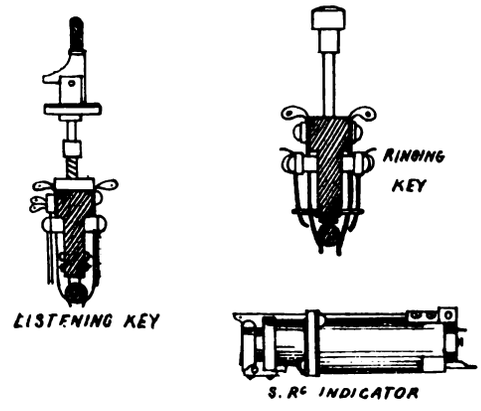
Messrs. Crompton and Co.—We learn that this firm have not yet been able to procure a site for their proposed new works. Land at Bedford, Colchester, and Ipswich has lately been offered, but the new site of the works is at present uncertain.

TELEPHONE EXCHANGES AND THEIR WORKING.*

BY DANE SINCLAIR, MEMBER.

(Continued from page 349.)

In an exchange of 5,000 subscribers, forming part of a system similar to that existing in London, there would be 1,000 junction wires—say, 500 outgoing and 500 incoming. The latter would necessitate the provision of five extra sections, thus bringing the total to 30 sections, whilst the former would involve the use of 500 additional jacks on each section, making the total number of jacks 165,000. It will thus be seen that a multiple board for 5,000 subscribers' lines is a huge electrical equipment. The number of soldered joints on such a switchboard, in connection with the jacks alone, is nearly a million, and the total length of wire is between 1,500 and 1,600 miles.



FIGS. 3, 3A, AND 5A.

The largest switchboard we have in this country is one which has been provided for taking the total number of jacks required for 8,400 subscribers' lines—*i.e.*, including junctions, 9,000 line jacks on each section—and for such an exchange, fitted on the ordinary multiple system, there would be required a total of 432,000 line jacks; so that, while we have only increased the number of subscribers' lines from 5,000 to 8,400—*i.e.*, 68 per cent.—we have increase the number of multiple jacks required from 165,000 to 432,000, or 162 per cent.

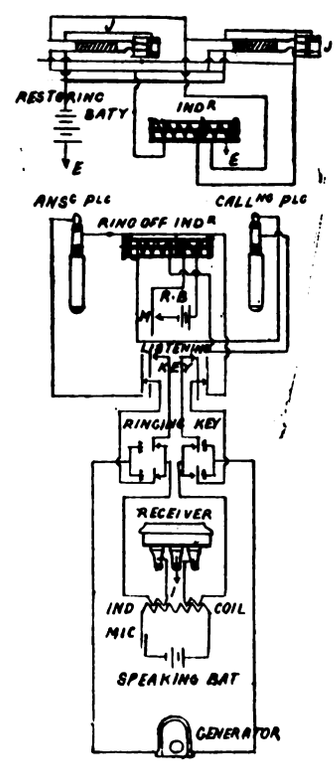


FIG. 4.—Diagram of Branching System with Self-restoring Indicator.

In Fig. 5, A, B, C represent a subscriber's line passing through separate sections of a switchboard. The wires come to the outer spings of jack A, and pass from the inner contacts to the outer springs of jack B, and so through all the sections. If the number of this subscriber's line is between 1 and 200, the wires, after passing through all the sections, would return to section A, pass through the local jack, and end in the

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

indicator. A third wire in connection with the barrels of the jacks is also carried through all the sections, and is normally an insulated wire. This is the test wire by means of which an operator ascertains whether or not the line wanted is engaged at any other section. When an operator replies to a subscriber she inserts a plug into the jack of his line. The tip and ring of the plug connect to the line wires, and the sleeve joins the barrel of the jack to a battery, the other side of which is connected to earth or a common return. To complete the connection the jack of the line wanted is similarly treated. Should either of these subscribers now be asked for at another section of the board, the operator there would touch the barrel of that subscriber's jack with the tip of the plug with which she proposed to make the connection, when a current would pass from the test wire through her telephone, causing a click, and so advising her that the line was engaged. The spring jacks are made up in strips of 20, mounted on two parallel pieces of vulcanite 1⅜in. apart. I submit a sample strip of these jacks. The front piece is 11½in. by ½in. by ½in., and the distance from centre

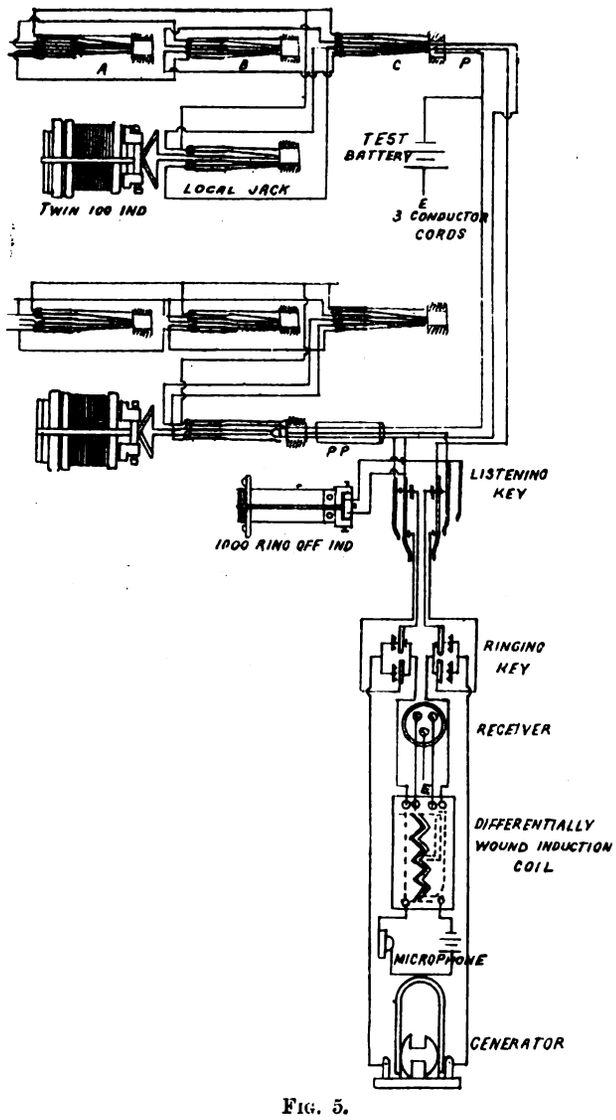

FIG. 5.

to centre of the jacks is ½in. The back part is slotted, and the springs which fit into these slots are shouldered, so that they cannot be forced out of position by the plug. Each jack has two long springs to which the line wires are connected, and these grip the plug. These springs rest on shorter springs (both being provided with platinum contacts), which are connected to the corresponding jacks in the succeeding sections of the board, and, lastly, to the local jack and indicator. A strip of metal is connected to the barrel of the jack and is carried to the back as a soldering tag, and to this the test wire is attached. These strips are secured to stiles in the upper portion of the board by special fasteners, which allow of any strip being readily withdrawn for repairing purposes. I have here a sample showing how one row of jacks is connected by cable with the corresponding row in the succeeding section of the multiple. The wires are carried throughout the switchboard in 63-wire cables, each cable serving 20 subscribers or one strip of jacks, and having three spare wires to provide for breakages. The copper conductor is No. 22 gauge, insulated with rubber and paraffined cotton. The wires are laid up in threes—two line wires and one test wire for each subscriber. Seven such strands are twisted together, and three such groups of wires are laid side by side and covered with cotton braiding saturated with paraffin. The size of the finished cable is about ⅞in. by ⅜in. The listening and ringing keys and their connections are the same as those shown with reference to small boards. The operator's telephone has received considerable attention of late years. It was, until lately, the practice to suspend the transmitter from the top of the board, and the receiver had to be held to the ear by hand. Now the transmitter is fitted in an aluminium case, which is fixed to a light breastplate of the same metal, and this is suspended round the neck of the operator, so that the mouthpiece is always conveniently placed for talking into. The receiver is also made up in a light form, and kept against the operator's ear by metallic springs or an elastic band. By the use of these instruments both her hands are left free for operating. The induction coil of the transmitter and the coils of the receiver are differentially wound, and the centre point of the latter coils is joined to earth to allow of the "engaged" test being obtained, and of the operator working earth-circuit and metallic-circuit lines on the same board indiscriminately. The earth being connected to the centre of

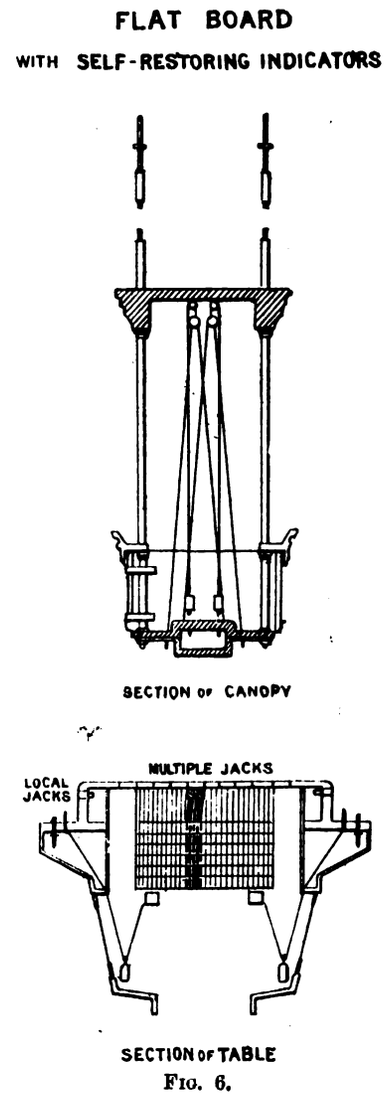

FIG. 6.

the differentially-wound coil has no detrimental effect on a metallic-circuit line. The boards just described are complete metallic-circuit boards, and are used very extensively in this country. They work satisfactorily on earth circuits, and, if necessary, may be employed on earth-circuit systems as transition boards. When on this system metallic circuits are joined to other metallic circuits they form a perfect metallic loop, but when joined to earth circuits one side of the metallic circuit is earthed at the exchange; the circuit so formed being but little better than a line with earth return throughout, the second line simply acting as a screen to lessen induction. All these connections are made in an exactly similar manner, the operator not having to distinguish between single and metallic circuits.

The problems in switchboard work have always been, firstly, How quickly can a connection be made? and, secondly, How can efficiency be best obtained? With reference to the first, the desired end is attained by reducing to a minimum the number of movements necessary, and making those movements as easy as possible. With reference to the second condition, in the earlier boards it was usual to leave the two line indicators in circuit when the lines were joined together;

Digitized by Google

and the first step taken to improve this was to cut one out, or to cut out both line indicators, substituting a special indicator for the purpose of receiving the subscriber's clearing signal. The electromagnet of this indicator was, however, directly in the circuit. It was observed that any such electromagnet in the line circuit cut down the talking very considerably, one indicator having probably as much effect in reducing the efficiency of the speaking as 50 miles of an ordinary aerial line. The next step was to increase the resistance and

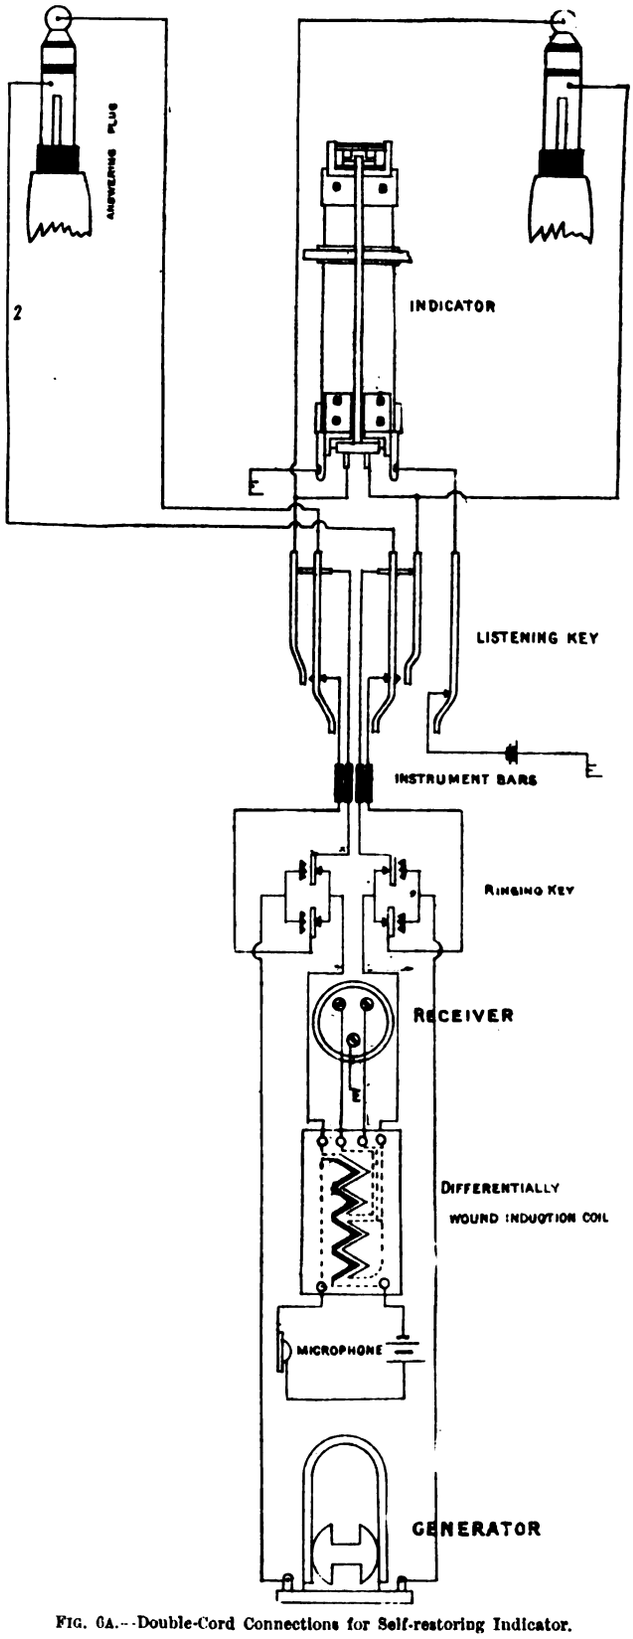

FIG. 6A.—Double-Cord Connections for Self-restoring Indicator.

self-induction of the ring-off indicator, and place it in shunt across the two lines of a metallic circuit, or as a tap to earth on single lines. It had also been found that trouble was sometimes caused by dirty contacts in the spring jacks. To obviate this difficulty some of the later boards have all the spring jacks wired in parallel, and the two line indicators, which are of special pattern, left in shunt. This system is sometimes called the "self-restoring" and sometimes the "branching" system; but, as the latter name had been correctly applied to other systems which had preceded it, and of which this is an extension, I prefer to use the former term. In this system (shown in diagram, Fig. 6 A and B) the work of the operator is lessened, inasmuch as the shutter of the indicator is automatically restored in answering the subscriber. This allows the indicators to be placed at the top of the boards, where space is not so valuable, and the spring jacks to be placed lower, thus bringing a much larger number within easy reach of the operator, and materially increasing the ultimate capacity of the Board. The general arrangement of this class of board is much the same as that previously described, except that, as just mentioned, the indicators are placed over instead of under the spring jacks. The apparatus, however, is somewhat different. The springs of the jacks are let into a solid slab of vulcanite. There are three of these springs, two being of equal length, and one shorter. The front of the slab of vulcanite carries two bushes, one behind, but insulated from, the other. The line wires are continuous throughout the exchange, ending at the subscriber's indicator. Branches are brought from these at each section, one to the short spring and the other to the inner bush of the jack. The two springs of equal length are joined, one to a common battery wire running round the exchange, and the other to the corresponding springs of all the jacks in the same line, and, finally, also to the indicator. This latter spring is also in metallic contact with the front bush of its own jack. When a plug is inserted in a jack, the tip comes into contact with one line through the short spring; the sleeve, through the barrel, with the other line; and the two springs of equal length are connected by an insulated metallic ring between the tip and the sleeve. The tip and the sleeve are joined to the two conductors in the flexible cord used for connecting two subscribers. It will be seen that when a plug is inserted into a jack the springs of the jack do not break any connection, and when the plug is withdrawn there is no contact point to be restored. The indicator (Fig. 3 A) consists of two separate single-coil electromagnets, both sheathed with iron, and fixed one in front of the other. To the back one, which has a resistance of 1,000 ohms, the line wires are attached. The front one, which has a resistance of 45 ohms, is connected on one side to the test circuit, and on the other to earth or to the common return of the restoring battery. When a subscriber calls, a heavy armature pivoted in front of the restoring coil is released, and falling forward a short distance lifts a light aluminium shutter, disclosing the subscriber's number. When the operator inserts the plug to answer the subscriber the heavy armature is drawn backward and held fast in its normal position so long as the plug remains in the jack. The aluminium shutter, of course, resumes its normal position at the same time.

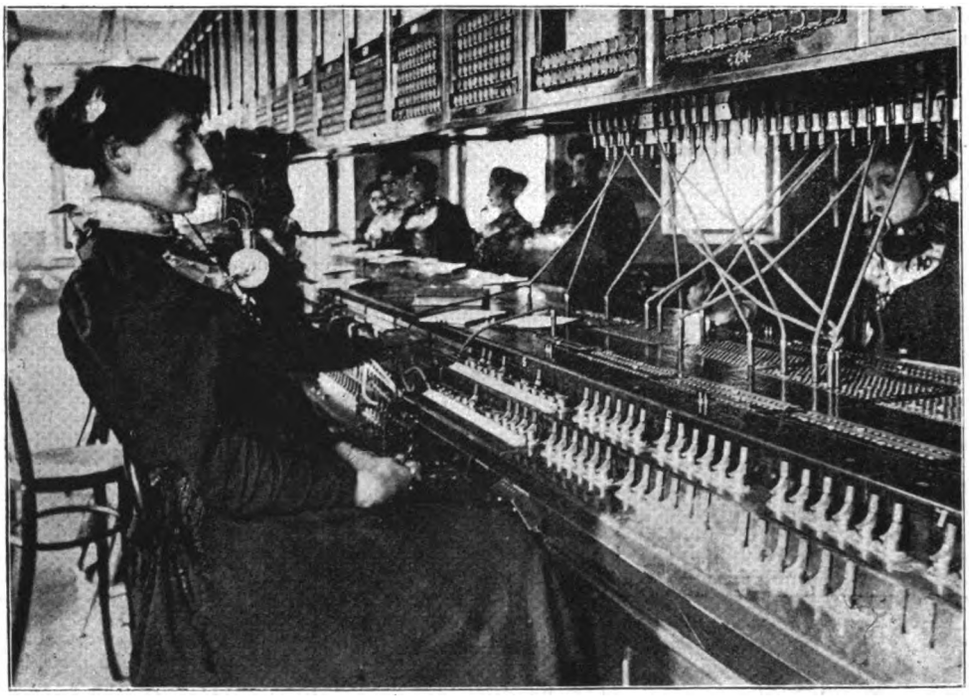
As before explained, the front bush of each jack is connected to this restoring circuit, and the connections of the operator's instrument are so arranged that when she touches this bush with the tip of one of her plugs part of the current is shunted through her receiver, showing her that the line is engaged. As one of the connections is dependent upon the contact between the inside of the bush and the sleeve of the plug, which must fit somewhat loosely, the plug is provided with what we call "umbrella" springs. The ring-off indicators are of the same pattern as those above described, but are so arranged in connection with the listening keys that when the operator's instrument is in circuit the indicator is locked, but is free to respond to the subscriber's ring-off current when, by pushing the lever forward, this instrument is out of circuit. This class of board with self-restoring indicators is being introduced into London at the same time as the subscribers' lines are being metallic-circuited, and this work will be entirely finished in a few months. One of the principal exchanges fitted with this class of board is that at Lime-street, City. It is to be noted that as these self-restoring indicators require permanent current to keep them locked while the lines are in use, special arrangements have to be made at each exchange for providing this current. As a typical case, I may mention that at Lime-street the current is supplied by 12 E.P.S. cells of 23 L type, charged by an Elwell-Parker dynamo running at 800 revolutions and giving an output of 45 amperes at 15 volts. This dynamo is driven by a Tangye gas-engine of 1 h.p. nominal. The engine also drives the generators which supply the ringing current. One-half of the cells—*i.e.*, six—are in use at one time, arranged in three groups of two each, and each group supplies current for one-third of the whole exchange—*i.e.*, about 1,300 indicators. The current for the operator's transmitters is supplied by a similar number of cells divided in the same way. In this case each group supplies current for about 30 transmitters. To prevent overhearing it is found essential that the circuit of each transmitter should be taken separately by direct leads from the terminals of the batteries. A duplicate set of cells is provided, and one set is being charged whilst the other is in use.

From what has previously been said as to the number of jacks required for an exchange with 5,000 subscribers' lines, and the increased proportion in the number required when the exchange is fitted for 8,400 lines, it is evident that, apart from

Digitized by Google

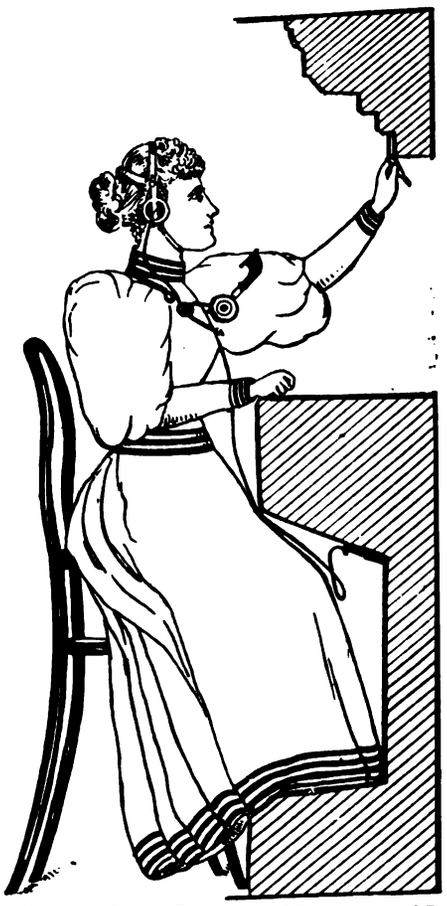
cost, the question is a very serious one; indeed, it becomes so serious that while on every hand it is acknowledged—and I think rightly acknowledged—that the multiple system is the best, a point may be reached where the vast number of jacks and large quantity of cables used introduce troubles almost equal to those previously overcome by the use of the multiple board. In America they are trying to meet the difficulty to some extent by the introduction of what is known as the "divided multiple" board, whilst I have endeavoured to meet it by the use of flat boards. The weak feature of the divided board is that no connection is made without being dealt with by two operators, and, consequently, the chief advantage of the multiple system—viz., that the operator who receives a call completes the connection—is lost. But with the flat board, fitted as I shall presently describe, this advantage is retained, whilst, broadly speaking, one-half only of the line jacks and cable are needed. It is about eight years since I commenced the use of flat boards, when a small one was fitted at Paisley. The working of this board proved that the flat board as a system, if fitted with the proper material, could be worked very successfully. I am aware that flat boards had been tried in this country before that date, and that some were in use in America; but, so far as I can learn, the number of jacks used was not less than that on the ordinary upright board. I therefore cannot see the reason for introducing them, unless, indeed, it was considered they were better flat than upright from an operating point of view. I am aware that there are in this and in other countries telephone engineers of the highest reputation who are not at one with me on the question of the advisability of introducing flat boards; but, after the fullest and most mature consideration and experience of their working for several years, I see no reason why they should not be used largely under certain conditions. When flat boards are fitted up in comparatively small exchanges, the saving on the jacks and cable is not equivalent to the extra expense of the framework, and therefore I do not recommend their use for small exchanges. But for large exchanges with from 2,000 to 8,000 subscribers' lines there is in my mind no doubt that this is the best class of board to use. The principal reasons for this opinion are: (1) That in consequence of the smaller number of jacks and quantity of cable used, better speaking results are obtained, and fewer faults occur. I have only to point out to you, as electrical engineers, that for an 8,000-line exchange the number of soldered connections is reduced in the flat, as compared with the ordinary upright board, by over half a million, to bring this point of efficiency forcibly before you. (2) In many cities it is very difficult to find switch-rooms large enough to take from 5,000 to 8,000 subscribers' lines; but with the flat-board system this difficulty does not exist to the same extent, as practically they take only half the floor space required for upright boards. There are likewise the questions of the cost of the boards, rent of switch-rooms, lighting, heating, etc., which bear some proportion to the space occupied; but these are secondary considerations, the principal one being efficiency.

I should like to make it perfectly clear that, while I consider flat boards the right pattern to use under certain conditions, I do not recommend their use in all circumstances. With self-restoring indicators, which do not require to be within reach of the operator, and may consequently be placed overhead, and the jacks for use with which have no breaking contacts, with the consequent trouble arising from dust, I consider them the right class of board to use. I also consider the flat board the best to use in connection with exchanges of all sizes worked on the call-wire system. Fig. 6 shows a section of the type of flat board with self-restoring indicator before referred to. The table carries the multiple spring jacks, the barrels all facing upwards. The local, or home-section, jacks, which are always used when answering subscribers, are at the side on the upright. The listening and ringing keys are fixed on a shelf at the side of the table, one half of the cords and plugs being fitted on the same shelf, and the other half in a canopy above the table, which canopy also carries the self-restoring indicators. The lower plugs are the answering plugs, and are inserted in the local jacks only; the overhead plugs are used only for making connection with the line jacks on the top of the table. The operators, each working 50 subscribers, sit on both sides of the flat table; and the 6ft. 6in. section of multiple jacks, which, on the upright board, is common to four operators with 200 subscribers, is here common to eight operators working 400



View of the Telephone Switch-Room in High Holborn.

subscribers. The framework is built of T and L iron, faced with wood, the details being as shown by sectional drawing at Fig. 6. Vertical oblong iron frames cross the tables at regular intervals of 11½in. for carrying the jacks and cables. The ends of the strips of spring jacks rest on and are fastened



View of Operator, showing Breast-plate, Microphone, and Receiver.

to the upper edge of these frames, the jacks being placed in a vertical instead of a horizontal position. The cables are carried by racks inside these frames. Each block of 100 jacks occupies a space of 11½in. by 2½in., and as there are six such blocks in the length and 10 in the width of the multiple it will be at once

Digitized by Google

seen that the board has a capacity of 6,000 lines. A special type of 63-wire cable is used. The cable is formed of seven groups of three strands of three wires each, laid side by side, and covered with braided cotton, the external dimensions of the cable being 1·312in. by 0·260in. The canopy is hung from the ceiling by rods at 3ft. 3in. centres, and, as before mentioned, carries the indicators and half of the connecting plugs and cords. The strips of indicators are fixed in the sides of this canopy, being hinged to allow of their opening outwards for convenience of inspection and repairing. In connection with flat boards I mentioned the call wire, and this introduces us to a system of working telephone exchanges differing largely from any I have previously described. The use of this system has been very much discussed by telephone experts. In the call-wire system each subscriber has, in addition to his direct line to the exchange, the use, in common with a number of other subscribers, of a wire known as the "call wire," which, starting from the exchange, is branched into the offices of, say, 50 subscribers. On this call wire the operator attending the subscribers is continuously listening in the exchange. The subscriber's instrument is fitted with a switch which enables him to place it in connection with the call wire, on which he asks for the subscribers he requires. These, of course, are connected on his direct wire, and are rung up by him, the operator not interfering with the connections until told on the call wire to clear. It will be seen from this that when a subscriber takes a long time to answer his bell (and there are many of them who do so, especially in London) he has to explain to the calling subscriber the reason of the delay, which would in all probability have been otherwise attributed to the operator. There being 50 subscribers connected to the telephone of each listening operator, it is evident that any number of them may try to speak at the same time; but here, as in all matters of business, common sense, as a rule, prevails, and a subscriber coming on to the call wire and hearing others talking to the operator does as he would do if booking a ticket at a railway office—*i.e.*, takes his proper turn, and so the calling is done without confusion and more quickly than with the indicator system. It must be clear to everyone who considers the matter that an operator cannot attend to two subscribers at the same time; and, generally, it is quite as satisfactory to a subscriber to listen until he hears that the operator is free as to ring time after time until the operator is able to attend to his call. It must be obvious, however, that the number of subscribers a call wire will accommodate is limited, and, as hereafter explained, great confusion would arise from overloading it.

(To be continued.)

INSTITUTION OF ELECTRICAL ENGINEERS, Mar. 26.

The PRESIDENT (Dr. John Hopkinson) in the chair.

A list of the candidates balloted for and elected appeared in our last week's issue.

The first business of the meeting was to receive the balance-sheet of the past year. As this had been printed and circulated among the members it was taken as read. (A copy of it was published in our columns last week.)

The **President** formally moved the adoption of the accounts.

Major-General Webber seconded this.

Mr. Raworth then said he had some remarks to make on the subject of the balance-sheet, but suggested that if it would suit the convenience of the meeting the discussion of the subject might be adjourned.

The **President** said that could hardly be done after the matter had been announced for that night. He, however, called Mr. Raworth's attention to the fact that an important paper was to follow.

Mr. Raworth said that it then became his duty to deal with the matter that evening. He had taken the trouble to look over the balance-sheet very carefully and to thoroughly understand it. At the outset he had come upon some peculiarities which had determined him to get to the very bottom of it, so that he might be able to assist other members to understand it. His remarks on the subject would be commendatory, explanatory, and critical. He found that their secretary had kept the accounts in a thoroughly good manner, and after he had taken the figures to pieces and constructed with them a proper balance-sheet as it should be constructed, he found the amount came out absolutely correct. It would be observed that this was the first time in the history of the Institution that they had been treated to a balance-sheet. On previous occasions it had always been called an estimate of assets and liabilities. Now, however, it was a balance-sheet, and there was a very great deal of difference between those two things Members might perhaps look upon him as an engineer, and not a skilled accountant, and therefore he had referred the figures to Mr. Hodgson and Mr. Garcke, who confirmed his corrections, and after that to a gentleman of the very first standing in such matters in the city of London. The latter said the balance-sheet was not very much worse than the balance sheets of such institutions generally were. They were always very lax. That was much to be regretted, because in such cases, more than in the case of a mercantile company, it was nobody's business to interfere, and the accounts were liable to get into a bad condition. Mr. Raworth then proceeded to criticise the figures of the balance-sheet in detail. One item they would find was for furniture—"as per last balance-sheet"—£214, less depreciation £14—£200. Now, this was their first balance sheet, and so far as he could see the £14 depreciation was nowhere accounted for. Then looking at the item "books, pictures, etc.," the sum total of that had risen from £1,043 to £1,093 in the year. Thus there appeared an appreciation of £50 without any expenditure to justify it so far as he could see except £8. 2s. for books and periodicals. He thought it would be seen from this specimen that the balance-sheet contained some very strange peculiarities. Now he looked upon an absolutely sound balance-sheet as the greatest security that the Institution could have for the safe transmission of its funds to future generations. The present members would pass away, and the best legacy they could leave their successors was a perfectly sound balance-sheet. Now was the proper time to secure it, for if they put it off, maybe until they had some defalcations, putting it right would be a very painful operation. He did not want, however, to press his amendment to a division that night, and if the President thought he had proved his case sufficiently he would stop there (No sign of assent was made by the President). Next, then he, would take a fund of which they were all proud—the Salomons scholarship fund Now, when he (Mr. Raworth) was making out a proper balance-sheet he could not at first make it balance by £570 13s. 6d. He had that more in assets than there ought to be, and had to find where it came from. Now, if money could get into a balance-sheet without being accounted for, it was equally possible for it to get out without being accounted for. He found at last that the Institution was indebted to Sir David Salomons for the sum in question, but they had not made any acknowledgment of the gift. He had learnt one thing during the last fortnight. He had learned that no one gave more attention to the affairs and honour of that Institution than Sir David Salomons. He had not only given them most liberally in money—they all knew he was a man of great wealth—but he had given them his time and attention as well. On a former occasion there had been a note made that a specific sum was the gift of Sir David Salomons, but with the sum at present in question when they looked at the balance sheet they would find no mention of the source of the gift. He did not know whether the Council would wish him to bring any further evidence——

The **President**: I must leave it entirely to you, Mr. Raworth, but I call your attention to the clock

Mr. Raworth: There is no limit.

The **President**: I know it. We will be patient.

Mr. Raworth, continuing, said he would next turn to another gentleman who must be nameless, for he had not been able to discover who it was, but that gentleman it appeared had given a sum of four guineas to the library fund, and they had done nothing with it. So far as the accounts showed, they had taken that sum and applied it to some other purpose. There was another matter he would bring before their notice. Their building fund had stood at £3,000, and they had transferred to it £500. It had also produced interest £90, but it only stood at £3,500 on the accounts instead of £3,590, so that it appeared that the poor fund had been swindled out of £90 somewhere. It was a very nice thing to possess £3,000 worth of capital, but if you did not get any interest on it you were not much the better off for it. If he were to present them with an oyster bed worth £10,000, but on the condition they were to have no oysters from it——

The **President**: I think, Mr. Raworth, that you might get along a little more rapidly without all this illustration.

Mr. Raworth: I will give you no more illustrations.

The **President**: Well, you have already occupied a quarter of an hour.

Mr. Raworth, continuing remarked that the Institution had a surplus of £1,173 16s. 6d. The Institution was founded for the purpose of promoting the advance of electrical science, yet they had only expended £23 on premiums while the Institution of Civil Engineers had spent £493. 9s 6d. It had been remarked that very good papers that might be read there had been taken to the Civil Engineers Possibly this was the cause. They had an enormous number of young members, and many would be willing to read papers if they could afford it. The drawings on the wall, for instance (Mr. Dane Sinclair's), must have cost something like £20 to make.

The **President**: I think Mr. Raworth, you are diverging upon matters which have not anything to do with the question to be discussed.

Mr. Raworth thought that how the money was expended had certainly to do with the balance-sheet. He had not wished to move this resolution if the Council would have met him on the point, but as it was, without referring to other items, he would move that the balance-sheet be referred back to the Council for amendment.

Mr. Mordey seconded the amendment.

The **President** remarked that he would simply ask the accountant to give any explanations that might be necessary as to the points raised.

Mr. Biggs (of Messrs. Wagstaff, Blundell, Biggs, and Co., the accountants to the Institution) said that the balance-sheet showed the assets and liabilities, as he understood them, in the usual form. Gentlemen who were unacquainted with accounts might have some difficulty in understanding an ordinary balance-sheet. On the right-hand side they would find the investments of the Institution. As to "furniture as per last balance-sheet," he was afraid that those words were a slip, because there was no last balance-sheet; but as to the £14 depreciation, Mr. Webb had fixed on the sum in consultation with the auditors as quite sufficient, and that

Digitized by Google

at the amount the furniture was taken at there would probably be no need for any further depreciation, since it would represent the value of everything 10 years hence. Great care had been taken in estimating the value of the overdue subscriptions. As to the item for books and pictures other than the Ronalds library, these had mainly been acquired by gift As to valuing them, he supposed that any six gentlemen would arrive at six different conclusions. It was quite sufficient for the purpose of the account to value them at £1,093 On the other side of the account, the different funds were set forth. The premium and other general funds must be shown separately under the provisions of their articles of association. The Salomons scholarship fund was also shown separately, as it was applicable to a specific purpose. The building and general fund comprised £6,700 odd. That the distinction was made between them was by the decision of the Council. The balance sheet boiled down to nothing showed the assets of the Institution to amount to £12 000 odd. He did not know that he could give any other explanation, and it seemed to him that the balance-sheet gave all the information necessary. Mr. Raworth had spoken of a sound balance-sheet, but he (the speaker) thought that when a balance-sheet showed £10,000 of assets that could be realised to-morrow against no liabilities to creditors they could not get into a much sounder condition. He did not know the name of the donor of the four guineas to the library fund, nor was it part of his duty to know it. With regard to there being no memorandum in the balance sheet that a certain sum was Sir David Salomons's gift, it seemed to him that the balance-sheet was not the place for remarks of that character, nor was it the place for them to express their gratitude. The donation was no doubt acknowledged on the minutes at the time it was made and the gratitude of the Institution suitably expressed.

The **President**: I will not waste any time after the amount of time we have unfortunately lost, but will at once put the amendment to the meeting.

Mr. Raworth: Nothing has been said in reply to my statements.

On a show of hands, 27 were held up for the amendment and 17 for the resolution, the greater part of the meeting voting neither one way nor the other.

The amendment was accordingly declared carried, and the reading of Mr. Dane Sinclair's paper on "Telephone Exchanges" was proceeded with. At its conclusion no time remained for its discussion, and after the usual vote of thanks the discussion was postponed to April 16,

THE PHYSICAL SOCIETY.

At the ordinary meeting on March 27, Prof. Carey Foster, vice-president, in the chair,

Prof. J. A. Fleming read a paper on "**The Edison Effect**" The Edison effect alluded to in the title of the paper is that if a metal plate is placed inside the loop of an incandescent lamp, then a galvanometer, of which one terminal is connected to this metal plate and the other to the positive lead of the lamp, will indicate a current passing from the lead to the plate. If, however, the galvanometer is connected to the plate and the negative lead, no current passes. Prof. Fleming, by connecting the poles of a condenser, firstly, to the two leads, secondly, to the plate and positive lead, and, thirdly, to the plate and negative lead, and in each case discharging the condenser through a galvanometer, has shown that after the lapse of a certain time, depending on the position of the plate, if the lamp is working at about four watts per candle, the potential of the plate falls to that of the negative lead. If the plate, instead of being inside the loop of the filament, is outside, then the time taken by the plate to acquire the potential of the negative lead is considerably longer. The space between the plate and the negative lead exhibits a kind of unilateral conductivity, for a battery having a low voltage is able to send a current from the plate to the negative lead, but not in the opposite direction. If, instead of using a cold metal plate, a second filament maintained in a state of incandescence by an insulated battery is used, then a current can be obtained between this filament and both the positive and negative leads. If the voltage on the lamp is raised considerably above that required to give 1 c.p. for four watts, then a current can be passed from the plate to the negative lead, while a galvanometer connected to the positive lead and the plate will indicate the passage of a current from the positive lead to the plate When the lamp is in this condition the space between the plate and the negative lead is very sensitive to the effects of a transverse magnetic field, such a magnetic field causing a large increase in the resistance. The curve showing the connection between the current passing from the positive lead to the plate and the volts between the terminals of the lamp is found to be discontinuous. As the volts are raised the current suddenly increases about tenfold, and it is while the lamp is in the condition corresponding to this upper portion of the curve that it is sensitive to the influence of the transverse magnetic field. By using a movable plate it has been found that the minimum current is obtained when the plate is nearer the positive than the negative lead. When an alternating current is used to supply the lamp, a continuous current can be obtained passing from the plate to either of the leads. If a small platinum cylinder is placed surrounding each of the leads, then a current can be obtained between each of the cylinders and the positive lead, but no current between the two cylinders. The largest effect occurs when a cylinder near the end of the negative lead is connected to the positive lead. The author considers that his experiments show that the resistance of a vacuum tube to the passage of a discharge would be greatly reduced if the cathode were made incandescent.

Prof. S. P Thompson said he would like to have some information as to the state of exhaustion of the lamps—whether this was such as is found in ordinary commercial lamps, or whether it more nearly approached that used by Crookes. A great change in the conductivity, etc., took place at an exhaustion slightly greater than that ordinarily found in incandescent lamps. It would be of interest to vary the size of the cathode, and to investigate whether the magnitude of the effects observed depended on the fall of potential per unit length along the filament. Another point was whether the position of the plate for which the effect was a minimum was the same for all lamps, or whether it changed with the volts and the length of the filament employed. Again, did the minimum occur at a certain fraction of the distance between the positive and negative leads, or, as was the case in some of the phenomena observed by Crookes, at a definite distance from either of the leads. These points might be investigated by means of a lamp with a straight filament where the fall of potential per unit length along the filament might be the same as with the loop-shaped filament, but the fall of potential per unit length in the vacuum would be different. The author's proposed experiment of heating the cathode by concentrating on it the rays of a lamp did not seem to him (Prof. Thompson) to differ materially from Crookes's experiment, in which an incandescent wire heated by a current was used as the cathode.

Mr. Skinner said that the heating of the cathode by means of a "burning-glass" could easily be carried out.

Mr. Blakesley pointed out that it would be quite possible to produce an increase of the current by means of a magnet.

Mr. Serle said that Prof. J. J. Thomson had shown that a magnet affected the conductivity of a gas.

Prof. Fleming, in his reply, said that no doubt the effects were largely dependent on the vacuum in the lamps. The lamps employed were exhausted to the ordinary commercial vacuum. Since it was found that the "treating" was more worn off the negative leg of the filament, and that a screen placed between the legs of the filament was more blackened on the side turned towards the negative leg, it would appear that the particles of carbon were shot off from the negative leg, and hence, perhaps, the charge was carried by these carbon molecules.

A paper of a purely mathematical character, entitled "**Notes on the Electromagnetic Effect of Moving Charges**," by **Mr. W. E. Morton**, was read by **Mr. Serle**, who also made some remarks on his own investigations dealing with this subject.

The society then adjourned till April 24.

COMPANIES' MEETINGS AND REPORTS.

METROPOLITAN ELECTRIC SUPPLY COMPANY, LIMITED.

The ordinary general meeting of this Company was held on Tuesday at Winchester House, E.C., Sir Massey Shaw presiding.

The **Chairman**, in moving the adoption of the report and accounts, a copy of which appeared in our last week's issue, first referred with regret to the illness of Sir John Pender, the chairman of the Company. Sir John Pender had guided the operations of the Company from its commencement, and he did not hesitate to say that the present position of the Company had been in the main due to the commercial ability and indefatigable energy displayed by Sir John Pender in its interests. Dealing then with the report and accounts, the chairman said their expenditure had practically been confined to five items—namely, buildings, £5,467; machinery, £5,016; mains £18,026; transformers and connections, £12,884; and meters, etc., £3,038. The expenditure on buildings was due to the Sardinia-street extension, where a large increase of generating plant had been required. The expenditure on mains was £4,000 more than in 1894. This had been necessary to meet the statutory demands on them. In consequence £31,640 more debenture stock had been issued, and shareholders would be glad to learn this had been done at a premium of 16 per cent., which had been placed to the capital account. The occasion of the fire at Sardinia-street buildings had been taken advantage of for a thorough overhaul of the boilers and furnaces, and the cost had been paid out of revenue. The maintenance of mains had amounted to very little on account of the loop wire system adopted by the Company. The parliamentary charges were due to the struggle that was constantly going on with competitors who wanted to take advantage of the work the Company had done and make inroads on their district. It was satisfactory to know that they were paying a 4 per cent. dividend and that the accounts were such that a very little more would place them on a sound 5 per cent. basis. As to the assistance received from the London and City companies at the time of the Sardinia-street fire, the Chairman remarked that though their trunk mains worked admirably it was necessary, in view of the largely-increasing demands upon them, to purchase an amount of current from the other companies. They were now, however, able to meet all their requirements, but the connections made would remain to the mutual advantage of all concerned. He might add that though the fire broke out between 6.30 and 7 in the evening, all the theatres supplied from the Company's mains, except one, were duly lighted that evening. He regretted that the Charing Cross Company had been successful in their application authorising

Digitized by Google

them to compete with the Company in the Strand. They had had that competition from the first in the St. Martin's district, and it might be taken for granted that anything that might be necessary to protect their interests would be done. Their engineer (Mr. Frank Bailey) had laid before the Board estimates of all work likely to be required up to 1900. They would shortly be wanting transformer sub-stations in some of their districts besides other work. A new issue of capital would be required, but in what form the Board had not yet decided. The shareholders would of course, have to be consulted on this point.

Admiral Lord John Hay seconded the resolution

Mr. Harrison Cripps as a shareholder to the amount of £20,000, said he was not altogether satisfied with a dividend of 4 per cent. To produce £100,000 worth of electricity it had cost the Company £68,000 more or less They might put it at 68 per cent. Now, it cost the Westminster Company 43 per cent, the St. James's 51 per cent., and the City of London 53 per cent.—*i.e.*, it cost them 18 per cent. more for production than these companies, which would amount to a 3 per cent. extra dividend. A large item in the cost of generation was the coal bill. For every £1 worth of current it seemed to cost the St. James's, Westminster, and City of London Companies from 2s. to 2s. 1d. for coal, while it cost them 5s 4d. Could the chairman explain this?

Mr. Geipel said Mr. Cripps had referred to the excessive expenditure on coal. It was the loop system which the chairman had spoken of that was in part the cause of it. They were using small transformers on the consumers' premises, and their transformer loss was consequently enormously greater than it would be if they were banked together upon the modern system.

The **Chairman,** in reply, said the coal consumption had been unduly large owing to the fire at Sardinia street, which compelled them to give their attention to keeping the supply going rather than effecting an economy of working. With reference to the mains, they had a class of mains which cost little but involved a greater coal consumption as compared with the other companies which had more expensive mains and a lower coal consumption. Besides, their district was a very large one, and they had a large number of mains that had not been taken advantage of by consumers to the extent that he hoped they would be eventually. The transformer sub-stations they intended constructing would meet the rest of Mr. Geipel's suggestions.

The resolution was then carried unanimously adopting the report, and authorising a dividend of 5s. per share, making with a previous dividend a rate of 4 per cent. per annum, and the retiring directors and auditors were re-elected.

TRAMWAYS ELECTRICAL TRACTION COMPANY, LIMITED.

A meeting of this Company was held on Monday last at 7, Poultry, E C., Lord Richard Browne presiding.

The **Chairman,** in moving the adoption of the report, a summary of which has already been given in these columns, said the report spoke for itself, but as allusion had been made in it to the proposed liquidation of the Company, a few words might be said as to the circumstances that had led to that being proposed. Many of them who were old shareholders in the Tramways Company of France would remember when the Rouen Company was not in a flourishing condition. The town of Rouen was very hilly, and the number of horses that had to be employed for extra traction was very large in proportion to the number required for tramways generally, and this caused great expense. The bulk of the shares of the Rouen Company were owned by the Tramways Company of France, which was an English company, on the Board of which he and some of his colleagues were directors. After due consideration, the Rouen Company determined to adopt the system of electric traction, and to carry out that purpose formed the Tramways Electrical Traction Company, whose articles of association, however, enabled it to do any other similar work The Tramways Company of France was wound up, and this Company purchased all the shares which that company owned in the Rouen Company. Those shares were the 15,000 ordinary shares of this Company. They then made a contract with the French Thomson-Houston Company for the due equipment of the line. Most of the Rouen lines were opened a few weeks ago, and the formal opening took place on March 22 with very great success. He believed this Company had conclusively proved the value of electric traction as compared with animal traction. The result of their success had been that certain offers had been made to them by French financiers to acquire all the shares held by this Company in the Rouen Company, and the negotiations had resulted in an agreement under which, while the capital of this Company remained absolutely intact—namely, 15,000 preference shares, £5 paid, and 15,000 ordinary shares of £1. 10s. each, fully paid—there was a balance which enabled them to pay interest of 6 per cent per annum on the preference shares and a dividend of £5 per share on the ordinary shares, leaving £2,089 to be carried forward. He considered that in returning the ordinary shareholders their capital, with the addition of a dividend of about 333 per cent., they had not done by any means badly. Of course, they might carry the Company on; but as they had realised practically their whole property, and had not at the present moment got any work in view, it would be better not to keep the shareholders' capital lying idle. If at any time the Board should see any prospect of undertaking a similar job, they had the shareholders' names and would be glad to invite them to participate in it.

Mr. J. B. Concanon seconded the resolution, expressing his regret that many of the old shareholders in the Tramways of France Company had not availed themselves of this opportunity of joining this Company. The Board had the very highest opinion of the merits of electric traction He might say that the Board had not by any means accepted the first offer, but had practically got their own price

The resolution was carried unanimously.

Mr. Austin moved a resolution authorising the payment of £2,000 to the directors as additional remuneration for special services They had a balance of £2,089 available for that and some interest accruing which would be sufficient to pay the costs of winding-up, so that it could be done without dipping into what the shareholders were to receive for their shares.

Mr. Beaton seconded this but asked if the repayment of £5 on the £1. 10s. could not be made as a repayment of capital so as to avoid the income tax on it It was really a case of the recovery of lost money so far as concerned many of the old shareholders in the Tramways of France Company.

Mr. Gilbert (of Messrs. Ashurst, Morris, and Crisp, the Company's solicitors), said it could not legally be done. It was also stated that the Board had considered the subject, and the **Secretary** said he had already received a communication from Somerset House.

The resolution was then carried unanimously and the meeting closed with the usual vote of thanks.

In acknowledging this, the **Chairman** stated that the greater part of the credit of the successful issue of the negotiations was owing to Mr. Concanon and Mr. Haldinstein.

There will be two more formal meetings to authorise the winding-up of the Company.

ANGLO-PORTUGUESE TELEPHONE COMPANY, LIMITED.

The ordinary general meeting of this Company was held last week at the Company's offices, 53, New Broad-street, Sir Alexander Armstrong presiding.

The **Chairman,** in moving the adoption of the report, stated that the Company continued to make good progress, the number of subscribers, both in Lisbon and Oporto, having increased during the year under review. They proposed to pay a dividend of 2½ per cent, and to place £3,000 to the reserve account, leaving £4,279 to be carried forward. The Board confidently hoped that in the future they would be able to augment this dividend The continuance of the high rate of exchange between the two countries had tended seriously to cripple the Company's financial resources. At the date of closing the accounts the number of paying subscribers in Lisbon was 1,212 and in Oporto 1,233, and the actual gross income in 1895 was over £16,000. Their relations with the Portuguese Government and the municipal authorities continued to be friendly.

Mr. C. L. W. FitzGera'd seconded the motion, and it was carried.

WILLANS AND ROBINSON, LIMITED.

Directors: Mark Robinson, M I.C.E. (chairman), Sir Gilbert A. Clayton-East, Bart., Captain H. Riall Sankey, R E. (retired), M.I C.E

Fourth half-yearly report of the directors and statement of accounts to be submitted at the ordinary general meeting of the Company to be held at the City Terminus Hotel, Cannon-street, E C., on Wednesday, April 8, 1896, at 3 p m.:

The Company's business continues to develop in a thoroughly satisfactory manner. Although, for reasons explained in previous reports, new business has been little sought for, the horse-power of Willans engines ordered in 1895 was 27 883, against 26,624 in 1894. These figures compare, it will be remembered, with 18,950 h.p. in 1893, the last and best year of the old company. Even more significant is the fact that in less than three months of 1896 the horse-power ordered has reached 22,200, a development which, if more or less exceptional, yet indicates the probability of a rapid growth of business in the future. The results of the half-year's work have been as satisfactory as in any previous period, notwithstanding that the operations of the Company have been hampered, even more than before, by inadequate and, therefore, uneconomical means of production. After writing off as depreciation from plant, patents, etc., the sum of £3,769. 13s. 4d, the balance to the credit of profit and loss account for the half-year (including £319. 10s 2d. brought forward from last half year) is £11,832. 14s. Out of this the directors propose that dividends be paid at the full rate of 6 per cent. per annum upon the preference shares, and at 7 per cent. per annum (as before) upon the ordinary shares, together amounting to £7,224. 19s. 5d. The amount payable to the directors, in accordance with the articles of association, is £1 286. 9s. 4d., and it is proposed, as on the last occasion, to carry £2,500 to the reserve fund. The balance, £821. 5s. 3d., it is proposed to carry forward. By the proposed appropriation the reserve fund, as the result of the first two years' working, will reach £7,646 9s. 11d, and of this sum the year 1895 will have contributed £5,000. The new works at Rugby are not yet in a position to assist in the production of engines, partly through delay by the contractor for the structural steelwork, partly from the necessity which has already arisen for extending the new buildings, and for commencing others which it had been originally intended to defer, the directors having judged it advisable to prepare for manufacturing operations at Rugby on a larger scale than was contemplated at the date of the last report. A number of the lighter new machine tools, intended eventually for Rugby, have been installed in a temporary building near Thames Ditton, where they are doing excellent service. The necessary authorisation for the contemplated issue of debenture

Digitized by Google

stock should now be given, and a resolution will be submitted to the meeting to that effect. In view of the remarkable expansion of the business, and of the necessity which may arise for even further extensions at Rugby, the directors think it will be prudent to take powers to borrow up to the limit allowed by the articles of association—viz, £112,500—but so far as they can foresee at present an actual issue of £75,000 may suffice. The exact conditions will be best left for settlement when the issue is made but there is every reason to believe that the Company will be able to place the stock upon favourable terms. The mortgages upon the Thames Ditton freeholds have been paid off The auditors, Messrs Cooper Bros. and Co., retire, but are eligible for re election.

Dr. BALANCE SHEET, DECEMBER 27, 1895.

OSWESTRY ELECTRIC LIGHTING COMPANY, LIMITED.

The annual meeting of shareholders of the Oswestry Electric Lighting and Power Company, Limited, was held at Oswestry on Friday evening last. Mr. E. Bremner Smith in the absence of the chairman of directors, Mr. Wynne Corrie), presided.

The report, which was as follows, was taken as read: "The directors beg to submit the accompanying statement of accounts to December 31, 1895, duly audited. The balance of profit and loss account is £33 6s. 1d., which the directors propose to carry forward. Up to the present date the directors have received and accepted 24 applications for the supply of current, including three contracts with the Corporation of Oswestry. Mains have been laid in the streets included in the compulsory area, the supply to which will shortly be completed, and the directors are about to lay mains in Salop-road, Victoria-road, and Queen's-road, and invite further applications for the supply of current in private and business premises in these roads. The total capital expenditure to date is under the amount estimated in the original prospectus. With the purpose of still further popularising the use of the electric light, the directors have decided to reduce, as from January 1, 1896, the maximum price to 6d. per unit, for payment within one month from due date. All current used in any half-year beyond the amount which would be consumed during 635 hours (two hours per day throughout the half-year) at the highest rate of actual consumption at any moment during the half year will be charged at the rate of 3½d. per unit. With a view to the further development of profitable operation, the directors invite applications for a limited additional number of ordinary shares.—A. WYNNE CORRIE, chairman. March 12, 1896."

The **Chairman** had great pleasure in moving the adoption of the report.

Mr R. Lloyd seconded.

Mr. Williams asked a question as to the £510. 6s. 6d. in the accounts as the cost of the provisional order.

The **Chairman** said it seemed an extraordinary and extortionate thing that a small Company like theirs should have to spend over £500 to get an order to permit them to spend their own money. Some part of that sum, however, would have been saved if the Corporation of Oswestry had not opposed the order, an opposition for which they got nothing.

The **Chairman** said the retiring directors were Mr. Corrie and Mr. Robert Lloyd, who offered themselves for re-election. He proposed that Mr. Wynne Corrie be re-elected. He was sure the deep and anxious interest he had taken in the Company from its formation left them no other course but to re elect him. He had been the backbone and strength of the Company, always helping them in every possible manner, and he had very great pleasure in proposing his re-election.

Mr. Jones seconded the motion, which was agreed to.

On the motion of **Mr. Williams**, seconded by **Mr. Perks** Mr. Lloyd was re-elected a director, and he briefly returned thanks.

On the motion of **Mr. Perks**, Messrs. Williams and Nicholson were reappointed auditors.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadrath, Prague.

Paris.—On April 9 there will be a limited competition at the Hotel de Ville for the supply of eight standards for the electric lighting of the Quai de Jemmapes and the Quai de Valmy.

Elberfeld.—Tenders are wanted by April 20 for the supply of four engines and dynamos and 174 lamps, conductors, etc., for the Prussian State Railways. Address, die Königliche Eisenbahn-Direktion, Elberfeld, Germany.

Bucharest.—The Postal and Telegraphic Administration of the Roumanian Government desires tenders by April 18 for the supply of 60,000 porcelain insulators (three sizes) and 10,000 porcelain shackles, for the State telegraphs.

Vienna.—Tenders are wanted by April 15 for the supply of fastenings and tubes for an extension of the Vienna telephonic system. Particulars can be obtained from the Austrian Administration of Posts and Telegraphs, Section 13, Vienna.

Rathmines and Rathgar.—The Town Commissioners want tenders by April 20 for the electric lighting of the new town hall (about 250 lights, with engine and dynamo), and also for telephones and electric bells. Further particulars will be found in our advertisement columns.

Chiclana de la Frontera (Spain).—Tenders are wanted for the electric lighting of Chiclana de la Frontera, near Cadiz. The

Digitized by Google

number of lamps required is 210 16 c.p., and the estimate is 15,000 pesetas (about £600) a year. The duration of the contract is 15 years, and tenders must be sent to the local authorities before April 6.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, 13, Comeragh-road, West Kensington, W. where applicants can obtain a memorandum explaining the local conditions. The tenders will be opened and considered by the Municipality of Lima, which reserves to itself the right of selecting that which is most approved or rejecting all if it thinks fit.

Edinburgh—Tenders are required by April 11 for the wiring of the police cells, Police-chambers, for the Lord Provost and Magistrates and Council. Specification, forms of tender, and plans of the building can be obtained at the office of the resident electrical engineer, 5, Dewar-place, Edinburgh, on deposit of £2 2s., which deposit will be returned on receipt of a bona fide tender. Tenders must be sent to Mr. Thomas Hunter, W.S., town clerk, by 10 a.m. on 11th inst.

Bedford.—The Electric Light Committee invite tenders for the supply and erection of the following plant: (Section A) one 240-b h p double-acting compound enclosed engine, (B) one 150-unit alternator, with stationary armature. Specifications, with terms and conditions of tender and contract, may be obtained at the offices of Mr. T. S Porter, clerk to the Urban Sanitary Authority, Town Hall, Bedford, on payment of a fee of 5s. for each section. Tenders sealed and marked "Electric Lighting, Section A or B," must be delivered to the clerk by April 4.

Bradford.—The Corporation invite tenders for the erection of a building required for the new electricity station at the junction of Valley-road and Lionel-street in the borough. Plans and specifications may be seen and bills of quantities obtained, free of charge, on application to Mr. Thomas Barker, A.M.I.C.E., architect at his offices, 5, Bond-street, Bradford. An assurance must be given by each contractor that he pays to the workmen employed by him not less than the minimum standard rate of wages. Tenders, endorsed "Tender—Electricity Works," to be sent to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by April 8.

Derby.—The Electric Lighting Committee invite tenders for the supply and laying of low-tension cables and junction boxes in the borough. Plans may be seen on application to Mr. J. E. Stewart, engineer, Electric Lighting Station, Derby, from whom a printed form of specification, form of tender, and schedule of prices may be obtained on deposit of £2. 2s. (to be returned on receipt of a bona fide tender). Tenders on the prescribed form must be delivered with the specification attached, enclosed in a sealed envelope, endorsed "Electric Lighting—Tender for Cable," addressed to Mr. H. F. Gadsby, town clerk, Town Hall, Derby, by 12 noon on April 13.

Cardiff.—The Corporation require tenders for the construction, supply, delivery, and fixing of two boilers of the dry-back marine or water-tube type, each to evaporate about 6,000lb. of water per hour, and one 250 to 300 kilowatt direct-driven steam alternator. Specifications may be obtained on application to Mr. W. Harpur, M.I.C.E. borough engineer, Town Hall, Cardiff Sealed tenders, addressed to Mr. J L Wheatley, town clerk Town Hall, Cardiff, and endorsed "Tender for Electricity Works," must be left at his office by April 6 A fee of £1 1s will be charged for a copy of the specifications, which fee will be refunded on the return of the specifications, accompanied by a bona fide tender.

Wigan.—The Gas and Electric Lighting Committee require tenders for the following: (Contract No. 1) cast mains and connections, (2) wrought-iron tube and fittings, (3) brass tube and fittings, (4) lead pipe, (5) firing and charging shovels, (6) brooms, (7) wood troughing and covering, (8) galvanised stove pipe and connections, (9) bar iron. The contracts will be for one year, commencing 1st inst. and ending March 31, 1897. Forms of tender may be had from Mr. Jos. Timmins, engineer, Gasworks, Wigan. Tenders, sealed and endorsed with the names of the articles tendered for, a sample of which must accompany each tender, to be delivered to Mr. J. J. Charnock, town clerk, Town Hall, Wigan, by April 13.

Harrogate (Yorkshire).—Tenders are required by April 7 for an electric light installation (about 400 lights), including generating plant, also telephonic and bell installations at their Harrogate premises, for the proprietors of the Prince of Wales Hotel. Tenders to be sent in a sealed envelope endorsed outside "Tender for Electric Lighting, etc., Prince of Wales Hotel, Harrogate," and sent in under cover of second envelope, addressed to Mr. Walter Leake, consulting electrical engineer, 30, Victoria-buildings, Manchester. Copy of specification may be obtained from Mr. Leake on payment of £3. 3s. deposit, returnable on receipt of bona fide tender and return of specification. Plans to be seen at 30, Victoria-buildings, or copies may be obtained on payment of £1. 1s.

Egremont.—The Wallasey Urban District Council require tenders for the following requisites—viz.: (a) steam alternators, switchboard, and accessories; (b) high and low tension concentric cables; (c) transformers. Copies of the specifications may be obtained on application to the engineer, Mr. J H. Crowther, Gas and Water Works, Great Float, near Birkenhead. A charge of £2. 2s. will be made for copy of each specification, to be returned on receipt of a bona fide tender. Sealed tenders, on the form to be provided for the purpose, addressed to the chairman of the Gas and Water Committee, and endorsed "Tender for Steam Alternators, Switchboard, and Accessories," or any other contract, as the case may be, to be delivered at the office of Mr. W. Danger, clerk, Public Offices, Egremont, by 4 p.m. on April 6. Each contractor will be required to enter into a bond with approved sureties for the performance of contract.

Antrim.—The Commissioners for the Control of Lunatic Asylums will receive sealed tenders up to 10 a m. on May 1 for the supply and erection of an electrical installation at County Antrim Lunatic Asylum. The tender should be sent in a sealed envelope, endorsed outside "Tender for Electric Lighting, County Antrim Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and should be accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tenders, and copy of specification, which has been prepared by Mr. J. H. Greenhill, M I E E, will be issued on application to the office of the Board of Control of Lunatic Asylums, Dublin, on deposit of £3, which will be returned to all persons who have sent in bona fide tenders. Plans can be seen at the office of the architect, Mr. John Lanyon, Northern Bank-chambers, Royal-avenue, Belfast.

Manchester.—The Lancashire and Yorkshire Railway Company invite tenders for the supply of the following articles during 12 months ending April 30, 1897: copper rivets, washers, and tubing, signal and telegraph fittings, and signal, telegraph, and electric light wires. Further particulars and forms of tender may be obtained on application at the Stores Department, Osborne-street, Manchester. Contractors cannot be allowed to tender to their own patterns, nor can the company's patterns be sent away for inspection, all being sealed and exhibited at Osborne-street. Tenders, properly endorsed, and addressed to the Directors, must be lodged with Mr. C. W. Bayley, secretary, Hunt's Bank, Manchester, by 10 a.m. on April 6. Separate forms of tender will be provided for each contract; parties applying are therefore requested to state the particular contract for which they propose to submit tenders.

London—The Shoreditch Vestry require tenders for: (Section A) high-speed engines, electric generators, switchboards, instruments, and street lamps; (Section C) motor transformers and starting switches; (Section D) accumulator battery and stands. All to be delivered and erected complete at the Vestry's electric generating station, Coronet-street, Shoreditch, or in sub stations within the parish. Specifications, with forms of tender, can be obtained from Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of £3. 3s., which sum will be returned on receipt of a bona fide tender. Contractors are at liberty to tender for any one of the separate sections or for the whole of the contract, but the Vestry will not consider any tender for a portion only of any of the separate sections Contractors whose tenders are accepted shall enter into a formal agreement, under seal, with sufficient sureties, for the fulfilment of their respective contracts. Trade union rate of wages and hours to be observed. Sealed tenders, endorsed "Tenders for Contract No. 4," to be sent by 4 p.m. on April 14 to Mr. H. Mansfield Robinson, vestry clerk, Town Hall, Old-street, E.C.

RESULTS OF TENDERS.

Brussels.—Among the tenders for a long list of miscellaneous articles for the electric lighting of the city (specification No. 34) the lowest for lot 2 (dynamo brushes) was that of Messrs. C. Trimborn, Schaerbeck, 793fr.; lot 3 (mica plates), Messrs. Boty, Brussels, 220fr.; lot 7 (500 grammes of platinum wire), Messrs. R. Dürr; lot 8 (phosphor bronze bars and wire), Messrs. Felten and Guilleaume, 4 300fr.; lot 10 (arc lamps), Société d'Electricité, Bouckaert et Cie., 1 743fr.; lot 11 (incandescent lamps), Messrs. C. Trimborn, 845fr.; lot 12 (cables), Messrs. G Boty, 902fr. The other lots were of small amount.

Shoreditch.—The following tenders were received by the London County Council for the wiring and fittings of the new fire-engine station in Tabernacle square:

Russell and Lennard (accepted)	£173	15	0
Drake and Gorham	186	5	6
Crompton and Co., Limited	219	0	0
Pritchetts and Gold	228	0	0
A W. Jackson	248	10	0

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The traffic receipts for the past week were £2,338.

Newcastle.—The National Telephone Company has just inaugurated a new central exchange in Pilgrim-street.

Glasgow.—The Tramways Committee of the Town Council have decided to discontinue lighting the cars by Froggatt's electric system, and to make experiments with a new oil lamp.

Dissolution of Partnership.—Messrs. W. O. Rooper and Tozer, of 11, Bridge street, Northampton, have dissolved partnership, and Mr. Rooper is carrying on business at Mill-street, Stafford, as he has done since 1884.

United Electric Wire and Telegraph Works, Limited—This Company has been formed, with a capital of £6,000, to carry on

Digitized by Google

business as electricians, electrical and mechanical engineers, and suppliers of electricity.

London.—The County Council have sealed an agreement with the Post Office in respect of the maintenance of telephonic communication between the Whitechapel fire-engine station and the Tower-hill street station.

Barcelona Tramways Company, Limited.—This Company has issued a circular to the shareholders inviting subscriptions to 3,000 5 per cent. cumulative preference shares of £10 each, part of 10 000 recently authorised.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending March 29 amounted to £1,133 as compared with £1,002 in the corresponding week of the previous year, being an increase of £131.

Direct United States Cable Company.—The Board of the Direct United States Cable Company have resolved upon the payment of an interim dividend of 2s. 6d. per share, free of tax being at the rate of 2½ per cent. per annum, for the quarter ending March 31.

Langholm.—At a meeting of the District Committee of Dumfries County Council Mr Paterson, Clerkhill moved that steps be taken to get the telegraph extended to Eskdalemuir, through the parishes of Westerkirk and Eskdalemuir. The resolution was unanimously passed.

Wealdstone (Middlesex)—At the meeting of the Urban Council Mr. King, in accordance with notice, moved "that the Council proceed forthwith to consider the question of lighting Wealdstone and surrounding district by electricity." Mr. Balk seconded, but the matter was deferred.

Brixton (London)—The local branch of the Social Democratic Federation has passed the following resolution: "That this branch is of the opinion that in the interests of the parishioners and true economy, the electric lighting of Lambeth should be owned and controlled by the parishioners through their elected representatives."

City and South London Railway.—The returns for the week ended March 29 were £918, compared with £932 for the corresponding period of last year, being a decrease of £14. The total receipts for the half-year terminating as above were £12 656, compared with £12 648 in the same period of the preceding year, being an increase of £8.

Chelmsford.—At a meeting of the Town Council the Lighting Committee intimated that Messrs. Crompton and Co. had furnished them with plans relating to the proposed new electric station, which the town had been asked to take over, but owing to the absence of information no report could be presented Negotiations were still in progress

Aluminium Products Syndicate, Limited—This Company has been registered with a capital of £6,000 in £1 shares, to enter into an agreement, made March 20, between George Mahaffy and the Company for the acquisition of certain patents and trade marks, and to manufacture and deal in alumina, aluminium, ferro-aluminium, brass, etc.

York.—At a parish meeting held for the nomination of overseers, it was unanimously decided that at the next meeting, to be held on April 9, the question of the proposed expenditure of £15,000 to £20,000 as per Prof. Kennedy's report *re* the electric lighting of the city be taken into consideration, with a view to memorialising the City Council on the matter.

Peterborough.—The Lighting Committee are proceeding very hesitatingly with the electric light question. A special meeting has been held to consider the report of Mr. Gill on the probable annual expenditure and income of the proposed scheme, and the result is that the committee propose to again ask the ratepayers within the area whether they want the light and how many lamps they would require.

Southampton.—On the motion of the Mayor, the Town Council have appointed the following committee to deal with all matters relating to the acquirement and working of the electric lighting of the borough: The Sheriff, Aldermen Bone and Button, Councillors Cawte, Denness, Exten, Harfield, Lemon, Le Feuvre Spranger, Walton; and Alderman Tilling, when his connection with the electric light company ceased.

Chesterfield and Midland Counties Institution of Engineers. A general meeting of the members of the institution (Mr. Emerson Bainbridge, M.P., president) will be held in the Municipal Science College, Green lane, Derby, on Saturday, April 4, at 3 p.m. The next general meeting of the Federated Institution of Mining Engineers (Mr. G. A. Mitchell, president) will be held in London, from Thursday to Saturday, June 4, 5, and 6 1896.

Address.—We are advised that Messrs. Clarke, Chapman, and Co., Victoria Works, Gateshead-on Tyne, have, with Mr. Jos. Moore as their representative, opened an office at 73, Bridge-street, Manchester. Among the orders which the firm have on hand at present may be mentioned seven 400-light dynamos for Messrs. John Musgrave and Sons, Atlas Mills, Bolton, and a 1,300-light dynamo and 1,000-light installation for Messrs. Kelsall and Kemp, Rochdale.

Aberdeen.—On account of the increased demand for electric lighting in the city, the authorities have decided to purchase a new 300 h.p. engine and dynamo for the electrical station in Cotton-street at the price of £2,660. An outlay of £130 for an addition to the switchboards has also been agreed to. The chief extensions of mains recommended embraces the Queen's Cross district, where a large number of consumers are already assured; Golden-square and Rosemount-viaduct, as far as the Bon-Accord Free Church; and George street, as far as Craigie-street.

Dundee Institute of Architecture, Science, and Art.—The third ordinary meeting of the institute for the session will be held in Gallery No. 3 of Albert Institute, on Wednesday evening, April 15 next, at eight o'clock, when a few descriptive and critical remarks by the president, vice-president, and other gentlemen will be given on the drawings and testimonies of study to be exhibited. The president, Mr. R. Keith, will take the chair.

Leeds.—A full meeting of the Tramways Committee has been held, when the chairman (Mr. Hannam) and the deputy-chairman (Mr. Henry) reported the result of an interview they had had with Dr. Hopkinson respecting the electrical overhead tramway system proposed to be adopted on the route from the Canal-gardens, Roundhay, along Roundhay-road. North-street, down Briggate, and on Boar-lane to Kirkstall. After a lengthy discussion a resolution was passed recommending that Dr. Hopkinson be called in by the Corporation to superintend the construction of the proposed new electrical tramway.

St. Pancras (London).—The Vestry have constituted the London and South-Western Bank as bankers of the Vestry's electricity account, and have appointed the manager for the time being of the Camden Town branch as treasurer of the account. At the meeting of the Vestry held as we go to press, Mr. Hodgson has given notice to ask if the Vestry have power under the St. Pancras Electric Lighting Act, or other Electric Lighting Acts, to grant loans to the authorities of churches and chapels for the wiring of the buildings, such loans to be repaid by instalments, and, if so, to move a resolution thereon.

New General Traction Company, Limited—This Company has been registered, with a capital of £170,000, to adopt and carry into effect an agreement expressed to be made with Edwin A King to carry on the business of contractors for the construction and equipment of tramways and railways with electrical or other mechanical power, and, further, to acquire or enter into any contracts, concessions, or other grants for the making or purchasing of and working any railways, tramways, telegraph and telephone systems, electric or other lighting works, and to carry on the business of general contractors in any part of the world.

Public Building Lighting—Messrs. Drake and Gorman's Manchester branch has just completed the electric lighting of the new infirmary, Lancaster, with about 300 lights. This installation comprises a system of medical switchboards, telephones, and electric bells. They have also just finished a large installation of 1,300 lights for the new technical schools, Salford, to a specification prepared by Mr Charles Turner, the borough electrical engineer. Other installations in hand are the County Technical Schools, Stafford; County Infirmary, Stafford; Birkenhead Town Hall; and a country-house installation for Mr. Frank Hollins at Greyfriars.

Britannia Motor Carriage Company, Limited.—This Company has been registered, with a capital of £100,000, to adopt and carry into effect an agreement made between James Ashton of the one part and William Pennington, on behalf of this Company, of the other part, generally to acquire, develop, work, grant licenses in respect of, and turn to account in such manner as the Company shall see fit any patent, patent rights, etc., and to carry on the businesses of electricians electrical and mechanical engineers, cycle and motor manufacturers, carriage builders, machinists, fitters, founders, tube makers, metallurgists, etc, in all or any of their respective branches.

Camberwell.—The Vestry have adopted the report of the General Purposes Committee, which contained the following: "Your committee have had under consideration an application from the National Telephone Company for permission to lay three tubes, with the necessary manholes, to carry telephone wire cables under the pathway along the north side of the Old Kent-road from the parish boundary near the Old Kent-road station to the parish boundary at Upper Grange-road. The committee recommend that this application be granted on condition that the pathways are made good at the expense of the company to the satisfaction of the surveyor to the Vestry."

Philadelphia—A large electric locomotive, built for experimental purposes by the Baldwin-Westinghouse combination, has been shipped from the Baldwin Locomotive works, at Philadelphia, to the Westinghouse Electric and Manufacturing Company, at East Pittsburgh, where the electric equipment will be put in. This locomotive is intended for passenger service, and has two four-wheel locomotive trucks, each with a 6ft. wheel-base and 42in wheels It is designed for 1,000 h.p., and the weight on drivers is 120,000lb. A short line has been built near the Westinghouse Electric and Manufacturing Company's works, on which this locomotive will be tried.

Fulham (London).—At the Vestry meeting Mr. Sayer stated that the Special Committee *re* Electric Lighting reported that they received the report of Mr. F. Hastings Medhurst with reference to the adoption of the electric light in the parish in connection with a dust destructor, and had instructed the clerk to have 200 copies of the same printed They had accorded Mr. Medhurst a vote of thanks for the clear and thorough way in which he had presented his report, and recommended that a cheque be drawn for £50, the agreed fee. The recommendation was agreed to. Mr. Marks was elected to fill vacancy on the committee caused by the death of Mr. H. T. Harrison.

Middlesbrough.—A project is on foot to establish an electric tramcar system that will connect Norton, Stockton, Thornaby, and Middlesbrough. The existing interests of the Imperial Tramway Company in Middlesbrough would be acquired, a connecting line from Middlesbrough to Thornaby laid, and the Thornaby, Stockton, and Norton interests of the Darlington and Stockton

Digitized by Google

Tramway Company acquired in those places. The District Fund Committee of the Stockton Corporation, however, object to the proposed overhead electric system, and if that Corporation will not grant the requisite permission the operations of the combination will be confined to Thornaby and Middlesbrough.

Tunbridge Wells.—Last week the borough electrician found it necessary to exercise his discretion and suspend the street-lighting. Owing to the rapid increase of private customers it may be found necessary to cut off the street-lighting altogether until the station is enlarged to the size originally contemplated, but which the shortsighted opposition of the Council prevented being carried out at the time. The mains are now to be extended into Camden-park and Sandrock-road. The latest hotel to adopt the light is the Clarendon, while three more houses on Broadwater Down are being added to the list. There are now over 7,000 lamps installed, which is really beyond the capacity of the present station. The builders have started the work of enlargement, and it will be pushed on as fast as possible.

Newmarket.—Speaking at an extraordinary general meeting of the gas company, the chairman (Mr. Robert Stephenson, J.P.) said there was a possibility of supplying the electric light in Newmarket without diminishing the consumption of gas. He was told on good authority that it was quite as cheap to use gas as coal, or even cheaper. At the present time they knew that several large houses in the town were lighted by electricity, and the motive power for driving the dynamos was supplied by gas-engines. If the Urban Council decided ultimately to provide the electric light themselves he had no doubt they would find that the best way would be to work in conjunction with the gas company and not in opposition to it. He did not think the electric lighting scheme could be a financial success.

Concerts.—Three very successful concerts have been given within the past week. The eighth annual smoker of the establishments of Messrs. Samuel Smith and Son, the Diamond Merchants' Association, the Diamond Merchants' Alliance, and Messrs. Gregory was held at the Freemasons' Hall on Saturday last, when a long programme was got through under the direction of Mr. Sam Wright, and a most enjoyable evening was spent by a very large company. The London central branch of the Electrical Trade Union also held a smoker at the Clerkenwell Town Hall on the same evening, at which there was a good attendance. On Tuesday evening last the City of London Electric Lighting Company gave a Bohemian concert at the Cannon-street Hotel, when a capital programme was presented to a crowded audience.

East Barnet.—At a meeting of the Valley Urban Council a letter was read from the National Telephone Company asking the Council for permission to erect ground poles along the Great North-road, for the purpose of connecting Barnet with the National telephonic system. The Chairman said, after the trouble they had taken to get the telegraph poles removed, he did not think the Council could agree to the erection of telephone poles along the road. Mr. Plowright said he could hardly agree with the chairman. In the case of the Post Office, they had plenty of money, but if they opposed the Telephone Company they would not put the wires underground, and Barnet might be deprived of telephonic communication with London for a long time. The Council, however, on the motion of Mr. Stutters, seconded by Mr. Valentine, refused the application.

Personal.—Mr. H. J. Dowsing has resigned his appointment as manager of the electrical heating and cooking department of Messrs. Crompton and Co., Limited, and has taken offices at 24, Budge-row, Cannon-street, E.C., where he will carry on the business of electric heating, adding several other special departments in the application of electricity. Mr. Dowsing has been nearly 15 years connected with Messrs. Crompton and Co., first on the outdoor staff, then London office manager, and finally manager of the heating department, which he established, the patents covering the processes bearing his name in conjunction with that of Mr. Crompton. Mr. Dowsing will be pleased to place his experience at the disposal of those thinking of adopting electric heating, and he will give special attention to the requirements of electric supply companies.

Shoreditch.—The Electric Lighting Committee of the Shoreditch Vestry have approved the specification for electrical plant as settled by the engineers, and tenders are now invited. At a meeting of the London County Council the Fire Brigade Committee reported as follows: "The new fire-engine station in Tabernacle square, Shoreditch, which is being erected by the Works Department, is nearly completed. As the station is within the area in which the Vestry of Shoreditch is empowered to provide electricity for lighting purposes, we consider it desirable that the public parts of the building, and the quarters of the officer in charge who is allowed light, should be lighted by electricity. We accordingly instructed the chief engineer to prepare a specification of the wiring and fittings necessary, and to invite six firms to tender for the work. We recommend that the tender of Messrs. Russell and Lennard be accepted, and that the solicitor be instructed to prepare a contract with them."

Guildford.—At a meeting of the Town Council a letter was received from the Board of Trade with respect to the system by which the energy was proposed to be supplied for the purposes of the Guildford Electric Lighting Order of 1894 A letter was also received from the secretary of the Guildford Electricity Supply Company giving notice that in one month it was the intention of the company to disturb the streets to lay the electric light mains. The mains would start at the old barracks, and would run under the pavement to North-street, up which they would run on both sides. The mains would, except at the top end, be laid on both sides of Spital-street and High-street. In Friary-street the main would run down the centre only, as would also be the case in Market-street. In other cases the mains would run under the pavement close to the houses 12in. below the surface, and in a V-shaped trough laid in with bitumen, and covered with boards. The matter was referred to the Paving Committee.

Lancaster.—The Electricity Committee have authorised the engineer to lay electric mains to houses in Dallas-road, and also to lay the necessary electric mains in China-lane, as soon as the street is ready for them. At the meeting of the Town Council Mr. Councillor Hall moved the adoption of the committee's minutes, and said they might take it for granted that the extension of the mains to China-lane would not be carried out until the property was erected. Mr. Councillor Bowness asked whether there had been any application made for the electric light in the China-lane and Dallas-place localities, or was it prospective. There seemed to be additional expenditure going on in connection with the electric light works. Mr. Hall said the main would be extended before the street was made simply to avoid laying a street and immediately breaking it up again. No doubt the property owners would take the light in China-lane, because it was quite as cheap and more effective than gas for shops. The minutes were confirmed.

Grimsby.—At a meeting of the Public Lighting Committee of the Corporation Mr. Alward proposed that the surveyor be instructed to draw out a rough sketch of what would be required, and that an approximate estimate of the cost be submitted at an early date. Mr. Crosby, in seconding, said that he would like the surveyor to bear in mind that they might have to provide for other lighting. Mr. Watkinson said that out of 28 boroughs using the electric light, 16 failed to make it pay. Mr. Barrett said that he had a list of boroughs that were using electricity, and his statement was nearly the opposite to that of Mr. Watkinson. He would suggest that, while they were considering the question of electric lighting, they should provide a refuse destroyer, which would supply them with the power, and at the same time destroy all the refuse of the town. It was ultimately decided that the sub-committee should choose one or two towns which had the electric light, so that a visit could be paid to them, and their plant be inspected.

Derry.—After the reading of a brief report from the resident electrical engineer (Mr. Christie) at a meeting of the Lighting Committee, Councillor Brown asked for some figures to indicate the expenditure incurred during the past four months in connection with the city electric lighting. The Chairman said that for four months and seventeen days there had been an outlay of £1,236 for the entire requirements in connection with the working of the station The proportion of interest on the loan for same period was in round numbers £500, and the cost for gas for same period £180, making £1,960 for the four months and seventeen days. To this might be added the expenditure in respect of two subsidiary schemes they had in connection with the original scheme spent £855 more than was borrowed. The subsidiary schemes, relative to the Guildhall electric lighting and the cattle pen electric lighting, cost £190 and £154 respectively. In regard to the working expenses it was but fair to say that the four months just elapsed were the severest for outlay in the year.

Oldham.—Major Marindin has held a Board of Trade enquiry concerning a proposal to construct an electric tramway from Oldham to Hyde, through Ashton, Audenshaw, and Denton. The British Traction (Pioneer) Company was represented at the enquiry by Mr. Sydney Morse and Mr. Sellon. The Town Councils of Ashton and Hyde and the District Councils of Denton and Audenshaw were also represented. Mr. Morse informed the inspector that the total length of the proposed tramway was seven miles six furlongs. The Lancashire County Council, the Limehouse Rural District Council Bardsley and Waterloo Parish Councils, Ashton and Hyde Town Councils, and Denton Urban District Council have all given their consent to the scheme. Mr. Chorlton, opposing the scheme on behalf of Audenshaw, said the company proposed to use a motive power which they knew nothing about from experience, and they (Audenshaw) thought it would not be an advantage. The Manchester Carriage Company already had communication with Audenshaw through a branch road.

Gulcher (New) Electric Light and Power Company.—The appeal in the matter of the Gulcher (New) Electric Light and Power Company, Limited, was argued before Lords Justices Lindley, Kay, and A. L. Smith on the 26th ult Before Mr. Justice Vaughan Williams, the liquidator applied for a declaration that Mr. James Murray was liable to pay calls on 300 shares of the Company. It appeared that Mr. Murray was the holder of some debentures which he agreed to exchange for preference shares on condition that 10s. per share was paid up on 37,423 shares. An allotment of the shares was made to him, and the liquidator sought to enforce that allotment. Mr. Justice Vaughan Williams held that the payment of 10s. per share on the 37,423 shares was a condition precedent to Mr. Murray's acceptance of the allotment, and dismissed the liquidator's application The liquidator now appealed, and after the case had been fully argued on his behalf by Mr. Gore-Browne, their Lordships, without calling upon Mr. Swinfen Eady, Q.C, who appeared for Mr. Murray, dismissed the appeal with costs.

Huyton (Lancs).—Major Cardew has held an enquiry into an application by the British Insulated Wire Company, of Prescot, for a provisional order to supply with electricity the districts of Huyton-with-Roby, Whiston, Rainhill, and Eccleston. Mr. Sydney Morse, for the company, stated that this was the second application. They supplied electricity for public and private lighting in

Digitized by Google

Prescot; and, having laid down a considerable plant, they sought to extend the mains to the districts mentioned They were prepared to lay out £10 000 at once, without risk or cost to the ratepayers, to give them the benefit of the light if they wished for it. Mr. A. G. Steel, on behalf of the Huyton and Whiston Councils, objected to the granting of the application on the ground that no alteration had taken place since the first application was refused; and the evidence was not sufficient to warrant the consent of the local authorities. When a *bonâ fide* expression of desire for electricity was manifested, the Councils would take into consideration the advisability of applying for an order themselves. Witnesses were called on both sides.

Godalming.—The special committee of the Town Council have applied to the Board of Trade for a provisional order for electric light, which order has been made, and will be shortly introduced in a confirmation Bill to be passed this session of Parliament. The committee have instructed the engineer of Messrs. Fowler and Co, of Leeds, to report on eligible sites for an electric light station in or near the borough, and to furnish detailed plans and cost of works necessary to do the same. They recommend that the ex-Mayor and Mr. Page be added to the special committee for electric light and that the committee have power to add to their number in the future if they consider it advisable At the meeting of the Council Mr. Carpenter said he understood that when they passed a resolution to get a provisional order that was all, and nothing would be done for a year at least. He must oppose this action of the committee with regard to the engineer. Mr. Girdlestone said this was entirely without prejudice. There would not be a penny put on the borough for preliminary work, and Mr. Carpenter's observations were somewhat premature. The committee's report was adopted.

Bristol.—At their last meeting the Electrical Committee found to their great satisfaction that the income would meet the expenditure—cost of maintenance and repayment of loans with interest—without any call upon the general district rate. The lighting of the streets by electricity for the six months has cost £1,446, that charge including not only the current, but the maintenance of the lamps. The committee decided to accede to a request for extensions of the mains from College-road, *viâ* Cecil-road, to the Mansion House, and to Lansdown-road, Victoria-square, and to the end of Guthrie-road, where it joins Pembroke-road. The committee had before them a report of a sub-committee appointed to consider extensions of the central station and of the machinery and plant, and they decided to recommend the Town Council to apply for leave to borrow £75,000 additional capital. This recommendation will be presented at the April meeting of the Council, when it will be explained that it is not proposed to lay out the entire sum at once. There are now 510 private customers on the books, demanding 30,850 lamps, and of these 490 customers have already been supplied with lamps to the number of 28 134. The balance of customers are being supplied as rapidly as circumstances permit.

Hampstead (London)—Upon the recommendation of the Lighting Committee, the Vestry have decided to place a 300-kilowatt dynamo, with the necessary steam and exhaust pipes, etc, in the proposed additional buildings at the central station, and the engineer has been instructed to prepare the necessary specification in order that tenders for such plant may be invited as soon as possible The Vestry decided to lay mains for the supply of electric light to private customers in Lambolle-road, Downshire-hill, and Spaniards'-road, it being stated that one house in the last-mentioned road is being wired for 400 8 c.p. lamps. Mr. Dobbs asked when the report on the electric light undertaking promised some time ago by the vestry clerk, would be ready. The Vestry Clerk replied that he had not yet been able to get all the required items, but he hoped to have the report ready before the next meeting of the Vestry. Replying to Mr. Randall, the Engineer said that the failure of the electric light in England-lane last Saturday night was caused by a breakdown of the low-tension cable on Haverstock-hill. Mr. Farmer asked when the work of lighting the High-road, Kilburn, by electricity would be taken in hand. If they were going to wait for Willesden, they might have to wait for ever. The Chairman said that at present the Lighting Committee had no reference on the subject before them.

Newington (London).—Major Philip Cardew, R.E, has held an enquiry on behalf of the Board of Trade with reference to the provisional order which is being promoted by the Vestry, with the object of obtaining powers under the Electric Lighting Acts in that parish. The London Electric Supply Corporation oppose the order on the ground that they were authorised in 1889 to supply the parish, and that they had since executed the necessary works and made the necessary arrangements for supplying the parish with electrical energy. The County of London and Brush Provincial Electric Lighting Company, Limited, and the Newington and Walworth Ratepayers' Association have also given notice of objection. The Vestry's reply to the petition of the latter body commences by doubting the existence of such a society. There is every reason to believe, says the Vestry, that the opposition arises from purely interested and party motives. With regard to the signatures, the Vestry points out that 464 of the petitioners (1,451 in all) are not entitled to a vote, their names not being on the parochial register. There are 1,204 householders in the compulsory area, but only 173 had signed the petition. The Vestry claims that electricity can be supplied by them without being a burden on the ratepayers. In fact, if the Vestry obtained the provisional order they would have to satisfy the London County Council that the installation to be proposed was a well-considered scheme, and one which would not inflict a burden upon the ratepayers, before any loan would be authorised.

Cheltenham.—The Town Council having applied to the Local Government Board for sanction to borrow £25,000 for purposes of electric lighting, Major-General H. D. Crozier, R.E, has held an enquiry at the Municipal Offices. There were present, among others, the town clerk (Mr. Brydges), the borough surveyor (Mr. Hall), and the electrical engineer (Mr. Kilgour). The Town Clerk explained that the application was made by the Corporation under the provisions of the Cheltenham Electric Lighting Order, which was put in force in 1893 and 1894 Application was made for a loan of £16,000 to carry out the necessary works, which were opened on March 16 1895. It was found in the course of the works that some alterations and additions would have to be made, and the expenditure exceeded the estimate by about £880. As time went on the demands for the light became so great that it was found necessary that further plant should be established, and that it was found necessary to make extensions without delay. In order to provide for this, application was made in August, 1895, to the Local Government Board for a further loan of £10,000. Now only, after seven months, that application was being considered. A considerable portion of the money had been spent, and it was found that in order to carry out the works that would be necessary next winter a further £15 000 would have to be raised. It was therefore decided to include both applications in the same enquiry.

Appointments Vacant.—The Commissioners of the Hackney Public Baths require an engineer and electrician at the baths. He must be a thoroughly experienced man. Salary £156 per annum. He will not be entitled to receive any pension or superannuation allowance. Applications, in candidates' own handwriting, with copies only (which will not be returned) of not more than three testimonials of recent date, marked on the outside "Application for the Appointment of Engineer and Electrician" should be sent to Mr. Geo Grocott, clerk, at the Town Hall, Mare-street Hackney, not later than 12 o'clock noon on Thursday, April 16, 1896. Personal canvassing not allowed. Selected candidates will, prior to the election, be required to attend the Commissioners and due notice will be given to them when their attendance is required.—The West Ham Town Council invite applications for the appointment of electrical engineer. Candidates must have had previous experience in a similar appointment with a company or corporation supplying electricity under parliamentary powers, and be competent to design and supervise the construction of the generating station, plant machinery, appliances, and cables necessary to generate and supply electricity for public and private lighting on the high-tension alternating system. The gentleman appointed will be required to devote his whole time to the work. The salary will be £300 per annum. Forms upon which application must be made may be obtained at the office of Mr. Fred. E. Hilleary town clerk, Town Hall, West Ham, and applications must reach him by 5 p.m. on April 8. Canvassing members of the Council is prohibited.

Hull.—The Electric Lighting Committee have had under consideration a report from Mr. A. S. Barnard, borough electrical engineer, dealing with the proposed extension of the electric lighting undertaking, and suggesting that distributing mains be laid in the following: Spring-bank, 1,070 yards, both sides; Beverley-road, 1,600 yards, ditto; Anlaby-road, 1,500 yards, ditto; Hessle-road, 1,000 yards, ditto; Walker-street, 600 yards, one side; Commercial-road, 400 yards, ditto; Waterhouse lane, 200 yards, ditto, and 100 yards, both sides; Porter-street, 500 yards, both sides; Midland-street, 100 yards, ditto; Osborne-street, 500 yards, ditto; Charles street, 450 yards, ditto; Waterloo-street. 650 yards, one side; Brook street, 400 yards; Wright-street, 400 yards; Queen's-road, 500 yards; Princes avenue, 1,100 yards; Derringham-street and Argyle street, 1,100 yards; Boulevard, 1,000; Brunswick-avenue, 400 yards; Fountain-road, 400 yards; and Park street. 800 yards—all on one side of the streets only. The total extension of mains amounts to 14 670 yards, which will serve the greater portion of the town. In addition to the streets enumerated, it may be desirable to lay distributing mains in East Hull to the extent of 2,650 yards, Witham, Holderness-road, Williamson-street, Drypool square (Upper Union-street), having 500 yards each, and Hedon-road, 650 yards. The extension would, however, depend upon the probable demand for current, for unless some such guarantee was forthcoming the expenditure would scarcely be warranted. The committee are not likely to have any difficulty in securing a suitable site for a station, as the Corporation have two or three plots suitable for the purpose

Cardiff.—Mr. G. W. Willcocks, M.I.C.E., Local Government Board inspector, has held an enquiry respecting the application by the Corporation to borrow £12,500 for the extension of the public electric lighting. There were in attendance Mr. J. L. Wheatley (town clerk), Mr. W. Harpur (borough engineer), and Mr. Appleby (electrical engineer). The Town Clerk explained that the town and population of Cardiff had rapidly increased and were increasing, that the Corporation had already borrowed £43,385 for electric lighting, and that the further sum of £12,500 was required for additional engines, boilers, and other plant, additions to the electric lighting station, and extension of the mains. The Borough Engineer also gave evidence, and said that since the initiation of the lighting in December, 1894, there had been an increased demand by the public, and this had really been in excess of the anticipations of the Corporation. At present they were supplying 10,000 8-c.p. lamps, and applications had been received for 2,500 more, which they could not supply because they had not the power. They therefore required additional buildings and plant, and unless that were done by next winter the present plant would not be capable of supplying the light. The proposed outlay would provide for an additional 10,000 8-c.p. lamps. Mr

Digitized by Google

Appleby also gave evidence as to what would be required. There was no opposition. The inspector will report in due course At a meeting of the Tramways Committee of the Corporation, the chairman (Mr. James Tucker) put before the members a scheme for the purchase of the tramways, which, he said, he had reason to believe would be accepted by the tramways company. It had been arranged—provisionally, of course—that several extensions should be made, and that electrical power should be used whenever the Corporation thought it advisable and were able to supply that power. In answer to Mr. Jenkins, the Chairman stated that the company were quite willing to adopt electricity when the Corporation thought it advisable Eventually a sub-committee was appointed to consider the details.

Mevagissey (Cornwall)—This town, which is almost buried among the hills on the south coast of Cornwall, and which has a population of about 2,300, is now lighted by electricity, the inauguration ceremony having taken place. To the Electricity Committee of the Parish Council is chiefly due the credit of installation. Through their exertions an electric lighting company was formed, with a capital of £1,500; and the contract for the installation was placed with Messrs. Veale and Co, electrical engineers, of St. Austell, who carried out the work in six weeks. The company have agreed with the Parish Council to light the streets for £48 per annum. The central station is situated close to the new quay, just outside the inner harbour, which enables the coal required for the engine to be landed direct from the ship into the store. On this site has been erected a plain stone building of one storey, with corrugated iron roof. Internally the premises are divided into three sections, for the engine and dynamo, accumulator batteries, and stores. The engine, manufactured by Davey-Paxman, of Colchester, is a compound under-type, semi-portable, with locomotive boiler, and of 12 h.p. nominal capacity, but capable of developing 30 h.p. It drives a Crompton 200-ampere 130-volt dynamo. Although the dynamo is capable of supplying all the electricity required for lighting the town direct, it is supplemented by a set of accumulators consisting of 60 Epstein cells, with a storage capacity of 360 ampere-hours. These are placed in a separate room adjoining the engine-house. When working at full pressure the dynamo is capable of charging both the mains and the accumulators at the same time. By means of a lever on the switchboard the strength of the current can be regulated. Five miles of mains have been laid, extending to all parts of the town. The mains are pure copper wire, supported on insulators, laid in creosoted wood conduits under the surface of the ground. They are capable of supplying 400 16-c.p. lamps at the same time. The streets are illuminated by 32 lamps of 16 c.p. and two of 32 c.p. The street lamps are bell-glass globes, 10in in diameter, suspended from plain iron brackets projecting from the walls of the buildings to which they are fastened. Over each light is an inverted opal shade, which acts as a reflector. It is intended to place a large lamp of 100 c.p at the pierhead, and 11 16-c.p. lamps round the harbour. As yet no private consumers have been supplied, but orders are rapidly coming in The charge to private consumers will be at the rate of 6d. per Board of Trade unit, which is equivalent to gas at 4s. per 1,000ft. For the present it will only be necessary to work the engine and dynamo twice a week, the accumulators storing sufficient electricity to light the town the rest of the week. The installation has been carried out under the supervision of Mr. F. Hedley for the contractors.

Bedford.—At the meeting of the Urban Council the first balance-sheet in connection with electric lighting was submitted as follows: Capital account—expenditure to December 31, 1895: to buildings, £3,526. 3s 4d.; machinery, £5 554. 13s; mains, including cost of laying same and paving, £5,483 12s. 8d.; transformers, £536. 5s.; meters, £530. 19s. 5d.; electrical instruments, £535. 3s. 8d.; legal charges, £268. 1s. 6d; engineer's commission, £793. 19s. 4d.; lamp columns (public lighting), £41. 8s. 1d.; miscellaneous, £66. 9s.—total. £17,336. 15s.; 1895—December 31, balance in treasurer's hands, £4,677. 7s. 6d.—grand total, £22,014. 2s. 6d. Receipts to December 31, 1895: by amount raised by loans, £22 000; miscellaneous, £14 2s. 6d.—total, £22,014. 2s. 6d. Revenue account—Expenditure to December 31, 1895: to fuel, including all expenses from December 6, 1894, to December 31, 1895, £399. 4s. 7d; oil, waste, and engine-room stores, £70. 14s. 5d.; wages at generating station, £290. 15s. 9d.; repairs, etc., £4. 3s. 8d.; wages of linesman, £43. 8s.; lamps (public lighting), £1. 4s. 6d.; rates and taxes, £39. 14s. 6d.; engineer's salary, £157 16s. 8d.; stationery, £4. 14s. 5d.; insurance, £20. 12s. 9d.; rent of land belonging to authority appropriated for electrical purposes, £20; balance carried to net revenue account, £90. 9s. 7d.—total, £1,142. 18s. 10d. Receipts to December 31, 1895: by sale of current from December 6, 1894, to December 31, 1895 at 6d. per unit, £1,114. 18s. 4d.; rental of meters, £28. 0s. 6d.—total, £1,142. 18s. 10d. Net revenue account — Expenditure to December 31, 1895: to County Fire Office—first instalment of loan of £12,000, £480; County Fire Office—one year's interest at 3¼ per cent, £390; total, £870 Receipts to December 31, 1895: by balance brought from revenue account, £90. 9s 7d.; balance, £779. 10s. 5d. — total, £870. Alderman Richards said this was the first annual statement the committee had to lay before the Council, and they thought that it was a satisfactory statement They would see that a balance of £90. 9s. 7d. was brought down towards the instalments and the interest. They had made such satisfactory progress with their customers that he felt they were justified in anticipating a very large increase in their income for another year. They began in December, 1894, with, of course, a small number of lamps connected and few customers. They began before the machinery was in proper order, but managed to supply their customers, who had gradually crept up in numbers. On June 30, 1895, they had 65 customers and the equivalent to 3,000 8-c p. lamps connected with the mains. On December 31 last there was a further increase of 109 customers, and the estimated number of 8-c.p. lamps was 4,105 All this was carried out on their first installation At the present time they had 5,240 lamps connected up, with 1,100 on order, and they anticipated a larger increase during the coming year. Taking a modest estimate they anticipated that at the end of the year there would be 8,000 8-c.p lamps, and if such was the case they would undoubtedly be coming very near to a balance, if they did not have a profit. The electric light was here, and it had come to stay, and it would undoubtedly increase. They had their plant and staff, and to a certain extent they had their customers. The expense would remain about the same, but for every unit of electricity they produced the cost of production would be 1d. per unit. So the moment they got another customer who wanted a unit of their electricity that gave them a profit, and that was why the committee anticipated a balance at the end of the year. When they visited the Board of Trade they were told that undoubtedly the plant for the generation of electricity had got almost up to the point of perfection, and that with slight alterations it would be inexpensive; that the royalties were falling off the lamps, and that everything that could be done to improve the lamps would be done at as little cost as possible. There was another matter with regard to street-lighting. He believed that Bedford was the only Corporation that had gone so thoroughly in for incandescent street-lighting. Many people had asked him why they did not have the arc lighting. He said now, as he had said from the first, that the expense of arc lighting was too great. They were satisfied they would get all they required with incandescent lamps, and he believed Bedford was the only borough in England where street-lighting was carried out on the three-wire system He moved the adoption of the balance-sheet, which was seconded by Mr. Taylor and carried, a vote of thanks being also given to the engineer, Mr. Johnson. The committee recommended that the common seal be affixed to the following contracts—viz., Siemens Bros and Co., Limited, for the construction of a switch-board, including the supply of necessary instruments, £400; W. Bradley, for the supply of 150 additional cast-iron lamp standards and fittings, £374. 5s. This was agreed to.

Belfast.—The electric lighting plant at Purdysburn Asylum consists of two dynamos nine kilowatts each (90 amperes at 100 volts), by the Electric Construction Company. They are direct coupled to Bumsted and Chandler high-speed engines, running at 460 revolutions per minute. The dynamos can be worked up to 130 volts at a reduced current when required for battery charging The battery consists of 56 K 17 type E.P.S cells with a capacity of 275 ampere-hours at a 55 ampere discharge rate. Two Cornish boilers (Penman) supply the steam for the engine, pumps, and washing department. A ring steam-main is provided so that steam can be taken two ways from either boiler, and steam-traps are connected to the main where required. The feed pumps and pipes are in duplicate, and can be worked singly or in parallel on either boilers or tanks. The main switchboard is by Crompton and Co., and is provided with battery regulator, automatic switches, and the usual instruments, shunt resistance switches, etc., and all arrangements for running the machines in parallel. The wiring is done throughout on the distributing-board system. There are no joints in the work, and all the lamps are wired back to the sub-distributing boards. The switches are key type, and can only be operated by the attendants The washing machinery is worked by electric motors Plans and specifications for the work were prepared by Mr. Victor A. H. McCowen, who acted as consulting engineer for the Board of Control, and the work was carried out by Messrs W. H Drennan, Belfast. Mr. Andrew Nance, manager to the Belfast Street Tramways Committee, has published a report made by him to the directors as to the working of electrical tramways on the Continent. He draws attention to the fact that his report, which was made last September, is almost identical in its conclusions with the report of the Corporation traction deputation, although arrived at from an entirely opposite point of view. The conditions that the committee annexed to their report seemed to him to be reasonable and such as the company could assent to with verbal alterations of no great importance. A special meeting of the Corporation has been held for the purpose of dealing with the tramways company's order under the Tramways Acts. The Town Clerk (Sir Samuel Black) said the order would, of course, have to be approved of by the Corporation, and then go forward to the Privy Council for confirmation. The Corporation, no doubt, were aware that the tramways company had a Bill in Parliament to empower them to use mechanical traction, and the Council also had, through the Press that morning, and directly, seen a copy of the report of the deputation upon the question, and it would be for the Council to deal with that report and say whether or not they would permit the company to use electricity on their lines. In any case the order would have to be modified in several respects, and he was not yet in a position to settle the order, even supposing the Corporation agreed to the proposal of doubling the lines, in any such way as would be satisfactory to the Corporation, the tramways company, or himself, and the wisest thing for the Council to do would be to adjourn the meeting for a fortnight or so, so that he could consider the question, and bring it properly before the Council, and let them decide whether electric traction should be allowed or not, and also to allow the tramway company to consider the report that had been made by the deputation. Mr. A. H. Bates (instructed by Messrs. C. and J. Black) said he appeared on behalf of the tramways company. He did not know whether the town clerk was fully aware of the conditions under

Digitized by Google

which the tramways company were prepared to accept their approval, because he thought the Council would be of the opinion that those terms were of such a character as to entirely disarm all opposition, and also to render the question of the adjournment unnecessary. The works authorised by the Order in Council were simply in the way of doubling the existing system. There was a reference in the Order in Council to mechanical power, but the Order in Council did not absolutely authorise the use of the mechanical power. Under those circumstances the only possible objection to the application before the Council appeared to be the question of whether or not it would be convenient in the public interest to have these lines doubled in certain streets. The tramways company was prepared to get rid of that question entirely by these terms. They were willing to accept the approval of the Corporation, subject to the conditions that they exercised their power in reference to any street, no matter what its dimensions might be, subject to the absolute veto of the Council. The Order in Council would be really reduced to enable the tramways company, as a corporation, to do certain things, but it would give them no power whatever against the Corporation. The Corporation would have it in their power to say whether, in reference to a single street, they would exercise their powers, and, of course, they would say what terms. The only other possible ground for adjournment was that the town clerk had not got time to consider the alteration. The company only asked for an Order in Council subject to such alterations as they might be advised by the town clerk to make, and seeing that the application had assumed that form he did not think there was any occasion for adjournment. After some discussion, further consideration of the question was adjourned. At a meeting of the Electric Committee the engineer reported satisfactory working, and the accountant submitted a statement of accounts, showing the result of the past year's working to have been a profit of about £300, which was considered fairly good for the first year.

PROVISIONAL PATENTS, 1896

MARCH 23.

6374. **Improvements in electric traction** Deeiré Korda and Anthony George New, Palace chambers, Westminster.

6397. **Improvements in conduits applicable for wires for conveying electricity.** John James Bate, 6, Lord-street, Liverpool

6407. **Method and apparatus for electrically coating articles with zinc.** William Stepney Rawson, 21, Greycoat-gardens, London.

6423. **Improvements in electric switches.** William Henry Dingle and John Mackenzie Urquhart, 23 Bucklersbury Mansion House, London.

6437. **Improvements in and relating to current collectors for electrically-actuated tramway vehicles with underground feed** Henry Harris Lake 45, Southampton-buildings, Chancery lane, London. (Union Electricitäts-Gesellschaft, Germany.) (Complete specification.)

MARCH 24.

6477. **An improved cord grip for electric light fittings.** George Owen Donovan, 49, Hartismere-road, Fulham, London.

6481. **Improvements in apparatus for supplying electricity to electrically-propelled vehicles on railways and tramways** Auguste Mégroz, 46, Lincoln's-inn fields, London. (Complete specification)

6487. **Improvements in controllers for electric motors** James Devonshire, 70, Chancery-lane, London. (Edward D. Priest, United States) (Complete specification)

6504. **Improvements in electrically illuminating devices for advertising purposes** Julius Lengyel and Armin Schlesinger, 45, Southampton-buildings, Chancery-lane, London.

6510. **An improvement in electric arc lamps** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

MARCH 25.

6524. **Improvements in electric counters** Frederick George Robinson, 15, Water street, Liverpool.

6549. **Carbon-holder for dynamo rubbers.** François Joseph Head, 8 Rue des Princes, Brussels.

6579. **Improvements in telephonic apparatus** Alfred Graham, 46, Lincoln's-inn-fields, London.

MARCH 26.

6606. **An electric cyclometer.** Thomas Gill Smith, 29, Poland-street, London.

6625. **A new or improved holder for telephone receivers** Arthur John Fippard, Upper-terrace road, Bournemouth (Complete specification)

6692. **Improvements in or connected with fusible electric cut-outs.** Alexander Bewicke Blackburn and Wilfred L. Spence, 47, Lincoln's-inn-fields, London.

MARCH 27.

6732. **Improvements in and connected with advertising devices operated by an electrical current.** John Hillary Collings, 73, St. Stephen's-road, Upton Park, London.

6751. **Improvements in or appertaining to carbons for electrical purposes.** William Phillips Thompson, 6, Lord-street, Liverpool. (Albert Lessing, Germany.)

MARCH 28.

6864. **Improvements in short-circuiting or safety devices for overhead electric conductors.** George Alonzo Jewett, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1890.

13635 **Electric welding.** Thompson. (Coffin.) (Second edition.)

1892.

14239. **Electric meters.** Hookham. (Second edition.)

20214. **Electrolytical apparatus** Boult. (Knöfler.) (Second edition)

1894

7801. **Electrolytical apparatus** Kellner. (Second edition.)

23697. **Electrodes.** Woakes

1895

3085. **Electric gaslighting device.** Jahnson. (Second edition.)

4476. **Electric medical appliances.** Braun and Sharman.

4660. **Electro-deposition of iron on copper, etc.** Hiorns.

5515. **Electric measuring instruments** Crompton.

8507. **Electric cut-outs.** Jeckell.

8573. **Electric cables.** Smith and Granville.

8664. **Arc lamps** Crompton and Pochin.

8727. **Electric switches.** Siemens Bros. and Co., Limited, and Lauckert

8728. **Secondary voltaic batteries.** Rhodin.

8905. **Galvanic batteries.** Menges.

8914. **Chloride of lead for electric batteries, etc.** Davis.

8994. **Arc lamps.** Jandus.

9286. **Electric switches** Hopkinson.

10029. **Electric lamps.** Singer and others

10792. **Galvanic batteries.** Elliott.

13636. **Electric signalling, etc.** Crandall.

19839. **Dynamo-generators or motors** De Puydt and Poncin.

1896.

156. **Regulating gas or electric light to railway coaches.** Proctor and Gill.

475. **Electric accumulators** Bersey.

1198. **Electric railways.** Darley.

2717. **Electric switches.** Royce and Claremont.

2767. **Telephonic systems.** Bennett and Somerville.

NOTES.

French Association.—This year's meeting of the French Association for the Advancement of Science has been held at Tunis, and has just closed. There were about 400 visitors. Next year's meeting will be held at St. Etienne, and the 1898 meeting will be at some Channel port, probably Boulogne, which is within easy reach of the British Association's meeting at Dover.

Testimonial.—Mr. W. Bathurst, who has held the post of assistant engineer at the Hampstead electric lighting station since the date of its opening, was last Saturday presented by Mr. E. Sayer with a testimonial in the form of a leather writing case, subscribed for by the indoor staff. Mr. Bathurst is leaving for the Cape of Good Hope at the end of next week. Mr. C. O. Bastian, who lately tendered his resignation, will also be leaving Hampstead in the course of the next fortnight.

Acetylene.—According to the *Moniteur Industriel*, the tramcar of the Compagnie des Tramways de Paris which has been fitted experimentally with apparatus for lighting by acetylene manufactured from carbide of calcium has been running regularly since February 27. The light is said to be extremely good and steady, and the result is considered satisfactory from the point of view of expense, though at present the precise amount of the daily consumption of calcium carbide is not known.

China.—Speaking of the growth of electric lighting in Shanghai, the *China Gazette* says a couple of years ago there were only about seven miles of streets lighted by electricity, for which 60 arc lamps were quite sufficient, and there was not a single incandescent lamp in or around Shanghai. Now it appears the electrical department of the Municipal Council runs 140 arc lamps, lighting some 15 miles of streets, and there are about 43 miles of line wire laid, in addition to 6,100 incandescent lamps of 8 c.p. each, for domestic purposes.

Budapest Exhibition. — In connection with the Hungarian millennial celebration and exhibition an electric underground railway has been constructed at Budapest, and was opened on Tuesday last in the presence of the Burgomaster and a number of high officials. The railway is about two miles long, and is a remarkable example of underground railway engineering. It runs from the Gisela Platz to the exhibition, so that passengers will be conveyed from the centre of the town to the grounds of the exhibition for a trifling fare.

Municipalising Telephones. — According to the British consular reports, the authorities at Amsterdam have been for some time anxious to put in force a policy of municipalisation so far as concerns the undertakings of public supply companies. It appears from the same source that the Amsterdam Telephone Company, to which at first very unsatisfactory terms were offered for the purchase of their installations on the expiration of their concession, eventually succeeded in obtaining acceptable terms for the transfer of their business to the municipality, but the attention of investors is called to the risks run by companies based on municipal concessions.

New Trade Paper.—A new sixpenny monthly has made its appearance under the title of "Aluminium and Electrolysis." As its name denotes, it is devoted to the production and use of aluminium. After an introductory note, mainly historical in character, the March issue has notes on the various purposes for which aluminium is adapted, and on the employment of British capital in its manufacture, with special reference to the British Aluminium Company. There are articles on the use of aluminium for cooking utensils and on "ferro-aluminium," and a quantity of miscellaneous notes, etc. The new paper is published at 3, Bolt-court, E.C.

The Crystal Palace Carriage Show.—In connection with the Crystal Palace International Horse-Drawn and Horseless Carriage and Roads Locomotion Exhibition, to be opened on May 2, there will be a chronological collection of cycles, marking the birth, rise, and development of the cycle. Those in possession of, and willing to lend specimens, should communicate at once with Mr. H. Hewitt Griffin, Putney. Mr. Cumming Macdona, M.P., has written to the *Times* reviving the controversy on the proper name for a self-moving cart. Mr. Macdona wants them called "automovers." If one begins a word in Greek, surely it is better style to finish it in the same language.

Edinburgh Observatory.—The new Royal Observatory at Edinburgh was formally opened on Tuesday by Lord Balfour, Secretary for Scotland. Lord Crawford and Sir R. S. Ball also took part in the proceedings. The new observatory contains a 15in. refracting telescope in addition to the old 2ft. reflecting telescope, and among the instruments in the building are the great Dun Echt electromagnet, which is said to be the most powerful in the world; a chronograph, with electrical appliances, which records the exact moment of every observation in every part of the building; and the carefully protected clock, connected by wire with Greenwich, which fires the daily time-gun at Edinburgh Castle and drops the time-ball on the Nelson monument.

Rontgen Radiations.—The theory of the new radiations still stands where it did. As Lord Rayleigh put it, in remarking that notwithstanding innumerable repetitions of experiments we had not yet got much nearer to understanding the phenomena, the difficulty lies in the impossibility of applying the ordinary methods of analysis. Almost nothing can be done with rays which we can neither reflect nor refract nor pass through doubly refracting crystals. It may, however, be worth recording that, according to an article in *L'Elettricità* of this week, it has been discovered that ordinary sunlight that has suffered abnormal refraction by fuchsine contains components which appear to have the power of passing through cardboard, leather, wood, or black cloth.

The Paris Telephone. — It is stated that the telephone service between London and Paris has been so successful that the postal authorities are about to lay a second cable across the English Channel to meet the increasing demand for the use of the wires, and that the work on the land wires is now being proceeded with on both sides of the Channel. The second cable is to be laid from Lydden Spout, about two miles to the west of Dover. The land wires of the present system terminate at St. Margaret's Bay, from which point the cable starts. At present the wires are only used between London and Paris, but it is stated that when the second cable is laid Manchester and Liverpool and some other large centres are likely to be directly connected.

Society of Arts.—The next course of Cantor lectures will be delivered by Prof. Henry A. Miers, M.A., on Monday evenings, April 13 and 20, the subject being "Precious Stones." The lectures will close with some remarks on artificial stones. Mr. James Swinburne will deliver a course of Cantor lectures on "Applied Electro-Chemistry" on Monday evenings, April 27, May 4, 11, and 18. Among the papers arranged for forthcoming meetings is one on April 22 on "The Perfected Photochromoscope and its Colour Photographs," by Mr. F. E. Ives. Papers at subsequent meetings

Digitized by Google

will be read by Captain Abney, on "Orthochromatic Photography;" by Mr. Hudson Maxim, on "High Explosives and Smokeless Powders;" and by Mr. E. W. Moir, on "Tunnelling by Compressed Air."

A Cotton Mill Plant.—Much attention is being given in the United States to the utilisation of water power in generating current both for general supply and in the case of individual enterprises. To the latter class belongs the electrical equipment of the extensive cotton mills of the Pelzer Manufacturing Company, which is now nearing completion. The power is derived from Victor turbine waterwheels, driving three 750-kilowatt three-phase generators, wound for 3,300 volts. The waterwheels turn at a speed of 164 revolutions per minute. The current generated at the power-house will be carried a distance of 3½ miles to Pelzer, where it will enter the mills and drive one 400-h.p. synchronous motor wound for high potential and several multiphase motors of varying capacities from 5 h.p. up to 110 h.p. The majority of these motors will be of the inverted type, suspended from the ceiling in the different rooms. They will receive the current at a low potential from step-down transformers, placed in the sub-station at the mills. The mills will also be lighted from the same circuit.

Presentations.—Last week a couple of presentations were made as testimonials of regard to Prof. W. Wilson, M.A., who has for five years and a half been in charge of the electrical engineering department of the Merchant Venturers' Technical College at Bristol. In the first place, the pupils of the boys' school of the college assembled in the great hall, when some handsome ornaments were presented to Prof. Wilson by those forms which had studied applied physics under him, and subsequently in the physical lecture theatre there was a meeting of the senior students of the college with the principal (Prof. Wertheimer) in the chair. The Chairman opened the proceedings by acknowledging, on behalf of the governors, his colleagues, and himself, the valuable services which Prof. Wilson had rendered to the electrical engineering department of the college, and expressed a hope that Prof. Wilson, in his new capacity as principal of the Salford municipal technical school, would meet with continued success and prosperity. Miss Fanny E. Jones, the senior lady student in the physics department, then presented to Prof. Wilson a large ornamental clock and figure, on behalf of the senior day students of the college, and Mr. James A. Seager, the senior student in the electrical engineering department, read an illuminated address which had been signed by the students. Prof. Wilson suitably replied.

A Graphic Description.—The following item of news comes from America. It is to be presumed that the town mentioned is Guthrie, in Oklahoma. Both town and State are still very new, but it is evident that in describing a lightning stroke, the local reporter is prepared "to see anyone else and go better." That numerous class of people who prefer artistic effect to absolute accuracy, ought to be satisfied at any rate. "The Baptist church at Guthrie, the steeple of which is 170ft. high, is being repaired, and two men were on a scaffolding at the summit of the steeple, engaged in painting it. Suddenly, a thunderstorm arose, and the sky was seamed with a series of vivid flashes of lightning. One stroke severed the ropes that supported the scaffold, which fell with a crash on the pavement below. The two men, however, saved themselves from falling by clinging to the top of the lightning-rod, but only to meet a more dreadful fate. A second stroke of lightning killed both the men and ignited their clothing, which burnt fiercely for 10 minutes or more, to the horror of the large crowd that was watching below. The stiffened and charred bodies remained clinging to the rod for three hours before the blackened corpses, seared beyond recognition, could be lowered to the ground." One can almost imagine the reporter standing at the door of the neighbouring saloon watching the event.

American Tramway Rules.—With a view to preventing the effects of electrolysis, the municipal authorities of Richmond, Virginia, have passed a city ordinance which is binding on the tramway companies. The principal points insisted on are: the rails should be electrically welded at the joints, or, if separated, they shall be bonded; for 10lb. to 60lb. rails one bond shall be used; for 60lb. to 90lb. they shall have two bonds; where joined the rails shall be drilled, the bond threaded and secured to the web with copper washers and an iron nut, the surface of the rail being first cleaned. The contact shall be made with bright surfaces, and shall have not less than 10 times the area of the bonding wire. The outside shall be thoroughly painted with insulating paint. Every third rail shall be cross-bonded. A continuous supplemental wire shall be laid in the centre of each track and connected to each rail every 300ft.; the size of this wire shall be equal in area to that of all the feeders for that section; in all cases the rails are to be connected to the negative 'bus bar. When the current is returned from the track to the power station there shall be provided and maintained a metallic circuit of old rails bonded together, or some similar metallic return of ample area; under no conditions shall the current be grounded at any point near gas or water mains. Whenever an ammeter indicates a current from the gas or water mains to the rails steps must be taken to stop it, a fine being imposed for non-compliance. If any damage is done to the water or gas mains, the company shall be held liable to the city.

Civil Engineers' Benevolent Fund.—The annual report and accounts of the Benevolent Fund of the Institution of Civil Engineers show that the fund, which has now been established nearly a third of a century, is distributing assistance to the extent of from £3,500 to £4,000 per annum. During the past year there has been a slight diminution in the number of applications for assistance, as well as a decrease in the amount of money granted, as compared with last year, the actual figures being 67 and £3,581. 6s. 8d., as compared with 74 and £4,096. 7s. 8d. respectively in 1894. It has been, however, again necessary to dispose of some of the reserve in order to meet the claims upon the fund. The income of the year has been from annual subscriptions, £1,696. 9s.; dividends on investments, £1,585. 10s. 2d.; donations not directed to be added to capital, £349. 2s. 6d.; and interest on deposit, £2. 10s. 11d.; or a total of £3,633. 12s. 7d. This, added to the proceeds of the sale of £250 3 per cent. stock taken from the rest account and producing £288. 10s., with the balance of £14. 9s. 7d. from last year, makes the total of £3,936. 12s. 2d. on the credit side of the account. On the other hand, the expenditure has been for grants, £3,581. 6s. 8d.; disbursements (for printing, stationery, postage, auditors' fees, and a small gratuity to the clerks), £115. 9s. 10d.; leaving unexpended £239. 15s. 8d., which completes the balance. The benefit derived from the distribution of so large a sum as £3,581 must be very great, and the committee and the institution may reasonably be congratulated on the amount. It is, however, impossible to continue it unless there is a strong subscription list, and the committee strongly urge the need for further subscriptions, since the ordinary income of the fund is insufficient to meet the calls upon

Digitized by Google

it; and the committee consider that from an institution numbering upwards of 6,000, there should not be difficulty in obtaining annual subscriptions and donations to a larger extent than £2,045. 11s. 6d., the amount given last year.

The Metric System. — In the holiday season newspapers have space to spare, and the *Times* has taken advantage of this to devote about three columns and a half to reasons against adopting the metric system. None of these are new, and most are not particularly forcible. However, we are taken back to Sir John Herschell and the old complaint that you can only divide 10 once by 2, and the remarkable virtues of the number 12 are enforced just as if our weights and measures went all by dozens and our arithmetic by duodecimals. Moreover, the metric system will carry with it the centigrade thermometer scale. *Non sequitur*, but if it did, what is deliberately preferred by the chemists and physicists ought to be good enough for gardeners and meteorologists. The only safe refuge for people who are afraid of a minus sign is to measure in absolute temperature. Unfortunately, a great deal has happened since the time of Sir John Herschell, and, among other things, the fact that the most important nations in the world, except England and her Colonies and the United States, have adopted the metric system. If a better than the metric system had been started at the beginning, it would no doubt have prevailed. Only it was not. The most remarkable thing, however, is in a second article at its conclusion, which falls into the form of a conversation, and is as follows: "But what about the immense facilities which the method of decimal calculation gives us? You seem ready to sacrifice all these? Not in the least. It needs only a small alteration in our method of numbering to make calculation by groups of 12 exactly similar to calculation by groups of 10; yielding just the same facilities as those now supposed to belong only to decimals. This seems a surprising statement; but I leave you to think about it, and if you cannot make out how it may be I will explain presently." From a third article it appears that this means nothing less than the alteration of the base of the scale of notation from 10 to 12, which is indeed an appalling and revolutionary proposition.

Poplar Trees as Lightning Conductors.—The second and concluding article by Dr. Cl. Hess on the question of how far poplar trees, and in particular the Lombardy poplar, planted in the neighbourhood of buildings may be depended upon to act as lightning conductors, has appeared in the *Elektrotechnische Zeitschrift*. In England it has always been an article of popular faith that tall trees close to a house increased the danger of its being struck by lightning, and though the risk might be considered negligible, and as a matter of fact is neglected, no one would suggest that; trees acted as a protection. It will, therefore, be no surprise to find that Dr. Hess decidedly pronounces against the idea that Lombardy poplars planted round a house will in any way protect it from lightning. On the contrary, so far from poplars planted near buildings being as good as lightning conductors, Dr. Hess shows that by their position they may become more dangerous than useful, and he endeavours to determine the best and worst distances. From a number of cases cited it is demonstrated that by increasing the number of trees the protection is not increased, and that absolute protection is not obtained even by a circle of trees. What happens is that the lightning jumps from the trees to the house, and it is stated that the danger in the current jumping from the trees to the roof of a building is considerable when the distance between them is less than 6½ft. As a house (possibly containing metal troughing and pipes) may very well give a better conductor and a better earth than the trunk of a poplar, this is just what might be expected *à priori*, and there will be little disposition to dissent from the conclusions reached. Any other result would, in fact, involve as a consequence that to stand close to a tall tree was a safe and advisable thing to do in a thunderstorm. In the course of the second article, some diagrams are given of a method of protecting a house in the immediate proximity of trees by running a wire electrically connected to earth along all the ridges of the building that come near a tree. Now, such an arrangement as this seems eminently adapted to promote the tree being struck, and, though the wire might be quite capable of carrying off the discharge without damage when it reached it, there might very easily be a good deal more in the way of broken branches and split bark than would be desirable.

British Association.—The local committee are well in advance with their arrangements for the sixty-sixth meeting of the British Association, which takes place in Liverpool, on September 16, under the presidency of Sir Joseph Lister, M.D., F.R.C.S., president of the Royal Society. The honorary local secretaries (Messrs. W. A. Herdman, J. C. Thompson, and W. E. Willink) state that invitations have been sent to the most eminent men of science in America and on the Continent, and a number of these it is believed will accept the invitation. Excursions will be organised to places of special interest in the district around Liverpool, and longer trips are being arranged to the Isle of Man and to the English lakes at the conclusion of the meeting. The reception-room will be in St. George's Hall, which is in the centre of the town and close to the chief railway stations, and about half of the sections will meet in that building and the immediate neighbourhood; while the remaining sections will be placed in University College, which is within half a mile of the reception-room. The lecture theatres and laboratories of the college will be available for demonstrations and for experimental illustration, and a loan museum will be formed in connection with the biological department. The evening addresses will be delivered in the Philharmonic Hall. One of the conversaziones will be held in the Town Hall and the other in the Museum and Walker Art Galleries, where the autumn exhibition will at that time be on view. There are to be the full number of 10 sections, including physiology, started at Oxford and suspended last year, and botany, started at Ipswich last year. The presidents of sections nominated by the council are as follows: Section A, Mathematical and Physical Science—Prof. J. J. Thomson, M.A., D.Sc., F.R.S.; Section B, Chemistry—Mr. Ludwig Mond, Ph.D., F.R.S., V.P.C.S.; Section C, Geology—Mr. J. E. Marr, M.A., F.R.S., Sec.G.S.; Section D, Zoology—Prof. E. B. Poulton, M.A., F.R.S.; Section E, Geography—Major Leonard Darwin, Sec.R.G.S.; Section F, Economic Science and Statistics—the Right Hon. Leonard H. Courtney, M.P.; Section G, Mechanical Science—Sir C. Douglas Fox, M.I.C.E.; Section H, Anthropology—Mr. Arthur J. Evans, M.A., F.S.A.; Section I, Physiology—Mr. W. H. Gaskell, M.D., F.R.S.; Section K, Botany—Mr. D. H. Scott, M.A., Ph.D., F.R.S. The office of the local secretaries is 5, Fenwick-street, Liverpool, to which communications and enquiries may be addressed.

Mountain Telephone Lines.—A short description has been given by Mr. J. W. Dickerson in the New York *Electrical World* of the system owned by the Colorado Telephone Company, which furnishes communication between all important points in the heart of Colorado. The main trunk line lies north and south, and extends

Digitized by Google

from Raton, in New Mexico, as far as Eaton, within 25 miles of the Wyoming border. Branches extend from the main trunk to all places of consequence as far west as Aspen. The company also owns a comparatively short connected system in New Mexico with Las Vegas as a centre. Isolated exchanges are maintained in several cities and towns, some of which may in time be connected with the long-distance system. The headquarters of the company are in Denver, and the telephone building in Lawrence-street is one of the best arranged structures of the kind to be found anywhere. Colorado is intersected by the Rocky Mountains, and consequently, of the 664 miles of pole line owned by the company, at least 300 miles have been built in mountainous districts, and in the extensions of the system in these localities the most interesting features of its construction are to be found. The building of these mountain lines has been expensive, as many difficulties have had to be surmounted, but the great outlay has, as a rule, been justified and has been appreciated by the public. The service is liberally patronised, so liberally indeed that the existing facilities are greatly overtaxed at some points, and plans for adding new circuits and providing additional improvements of various kinds are under consideration. In ordinary construction the poles are set 42 to the mile, but in many places the lines are full of sharp turns so that the number of poles per mile goes up to 75. When going through trees the timber is cleared for 200ft. on each side of the line, as the district is subject to severe storms, and the line would otherwise be liable to frequent interruption from tree falls. The construction gang therefore have to be woodmen as well as linesmen. In the rocky ground making the holes for the poles is often a serious matter. On the Leadville-Aspen line, which crosses the "Continental divide" at an elevation of 12,000ft. above the sea-level, aerial construction had to be abandoned at the summit in favour of a cable, as it was found that even No. 6 wire with poles every five yards would not stand when sleet accumulated on it. In spite of the southern latitude the climate in the Colorado mountains is exceedingly severe, and in the winter-time linesmen doing repairs have to travel on snowshoes.

Transformer Losses.—Writing on the subject of central-station working in the New York *Electrical World*, Mr. R. E. Richardson makes "A Few Suggestions to Station Owners as to the Selection of Transformers." The suggestions amount to this—that wherever possible large transformers should be used instead of small ones, and that if an alternating-current plant is not working as economically as could be desired one of the first things to be investigated is whether the loss is not due to using an unnecessary quantity of small transformers. The central-station engineer has realised for some time that if he wished to reduce his coal bill and working expenses and increase the income from his plant he could do so by simply replacing small transformers with larger units and bunching his secondaries. It is evident, however, that in the case of factory lighting, etc., or lighting in a thickly-populated town, large units in transformers can be used to a much better advantage than in the case of widely-distributed residence lighting, as in that case the cost of copper or loss incurred in the secondaries in attempting to use large central units would ordinarily be more than the extra loss due to the use of a number of small transformers. Mr. Richardson, however, says the fact is not so well appreciated in America as it should be. A short time ago his attention was called to two plants, both of some 3,000-light transformer capacity—the largest transformer in use on one plant was a 30-lighter, and the bulk of the units were 5 and 10 lighters, though the local conditions were favourable to large units. Taking the loss in leakage and working it back to the coal pile, and then putting larger units in place of the existing transformers, the saving in coal alone by the change would, in a little over a year, pay for the entire new equipment of transformers, assuming that the old ones were thrown on the scrap heap. In the second case the owner was about to get some new station machinery, "as his present plant was loaded to its limit." Upon investigation, it was found that by putting in new transformers, instead of a new engine and dynamo, he would reduce his loss due to leakage to such an extent that not only would his present station apparatus not be overloaded, but he could even connect more lamps to his present lighting plant. The same conditions can be found to a greater or less degree throughout the United States. It is further pointed out that even where water power is available or coal is cheap, "as the efficiency and regulation of a transformer are interdependent, and the leakage current determines the efficiency, the station operator should most carefully take into consideration both sides of the question, and try to select those transformers which will give to him the minimum leakage current without sacrificing his regulation to such an extent as to give poor service to his customers or unduly shorten the life of his lamps." Too often failures have been attributed to the system adopted, when the fault should have been laid directly at the door of the designer of the plant. Mr. Richardson compares a central station with an alternating system to a business house with a number of employés, each one an expense to feed and maintain. "A central station is a business house, not selling and delivering boots and shoes, dry goods and groceries, but electricity, and that it must be run on the same business principles and with the same business precaution that is taken in other lines of business." Reasons such as are indicated above may account for the smaller favour with which alternating current systems are regarded in America.

The Telephone Service.—The transfer of the trunk telephone lines to the Post Office on Saturday last has been the occasion of a special article in the *Times*, which considers it to be a first step in the nationalisation of the telephones. When the transfer has been fully completed according to the scheme of joint working to be undertaken by the Post Office and the National Telephone Company, "the exchanges of the company are to be connected with the nearest post offices, and at such post offices call offices are to be established. Thus, any person wishing to speak to a subscriber to any exchange may do so by calling at the principal post office of the town and asking to be put into communication with his correspondent. More than this, any person in, say, London wishing to speak to someone on, say, the Brighton exchange may call at the proper post office in London and be 'put through' to his friend at Brighton. Hitherto, not only communications between persons in the same town, but between one town and another have been almost exclusively confined to subscribers to telephone exchanges. In future, such conversations may largely take place between persons who use the telephone only for special purposes, and not habitually. Of course, the extent to which such casual conversations are held will depend upon the charges made for them. In most cases, both the Post Office and the company will be concerned in the transmission of the message. The Post Office charge for the use of its trunk wires must obviously be fixed, and will compare favourably with the charges hitherto made by the company, but the company may or may not think it necessary to make a charge for the terminal service—which seems, indeed, to be as much in

Digitized by Google

the interests of the company's subscriber as in that of the caller." It is further added that a subscriber to an exchange may, when he wishes to send a written telegram, speak his message to the Post Office, and ask that it may be despatched over the telegraph wires in the ordinary way. Or he may ask the Post Office to send him a messenger and give him a letter or parcel to be carried express. "Thus the facilities now offered by the district messenger system will be at the disposal of every subscriber to a telephone exchange without the burden of an extra subscription and the inconvenience of a separate apparatus. Instead of summoning a boy from the District Messenger Company by turning the handle of that company's special call-box he will speak to the Post Office over his telephone, and thus at once secure a Post Office boy. And it is to be borne in mind that the charges of the Post Office for express letters are very low. It is a subsidiary advantage of the connection of exchange subscribers with the Post Office that the express messenger service can thus be carried on without the erection of an additional network of overhead wires. Again, a telephone subscriber wishing to catch a mail at the last moment may telephone a letter to be despatched by the ordinary post. And in the opposite direction arrangements may be made for the telephonic delivery of telegrams into a subscriber's office, the delay of delivery by messenger being thus avoided." After a summary of the circumstances under which the National Telephone Company acquired a practical monopoly of the telephone service in this country, the article concludes: "The Post Office has, in fact, as to the trunk-wire telephone business of the country, bought up for a large sum, the particulars of which, we believe, have not yet transpired, the competitor whom it launched in business 16 years ago. It remains to be seen how the public will be served under the new working agreement, and whether the residue of this same competitor's business will have to be acquired for a yet higher price, or whether the license, which still holds good for some 16 years, may be allowed to run out without injury to the development of that wonderful means of communication which is supplied by the telephone."

American Safety Rules.—The conference called by the Committee on Standard Rules of the National Electric Light Association has taken place at the headquarters of the American Society of Mechanical Engineers, New York. Mr. William J. Hammer presided, and stated that the object of the meeting was to harmonise as far as possible the various interests, and, if possible, to produce a standard set of rules for electrical construction which would be recognised and accepted by all who were engaged in such work. After some general discussion the conference took up the subject of rules on the basis of the six different codes now in use in the United States—namely, those of the Association, National Board of Fire Underwriters, Associated Factory Mutual Insurance, English Board of Trade and Phœnix Rules (new), German Code (new), and the Edison Illuminating Company. One point brought out in the discussion was that the rules of the N. B. F. U. were primarily composed with reference to the fire risk involved, while those of the N. E. L. A. had in view good construction. While the two objects are similar, they are not always the same. After discussion on the means of enforcing the rules when they were adopted, there being no central authority in America like the English Board of Trade. Mr. A. E. Kennelly read a paper on the safe carrying capacity of wires. The table of capacity recommended by the English Board of Trade and recommended by the N. E. L. A. allowed a rise in temperature of 10deg. to 12deg. C. The table of capacity of wires in use by the N. B. F. U. allowed a rise in temperature of from 25deg. to 50deg. F., and he thought this was too near the safe limit. Mr. Merrill said many contractors had complained that that limit was much too low, and Mr. Jones said that the trouble really was to make people stick to the limit originally intended for the wires. In case of an office building, for example, an outlet that was originally intended for five lights would often have extra lights or fan motors plugged in by the building electrician without consulting anybody, with the result that many circuits were loaded up to double their original capacity. Inspectors could not be expected to see all these things, and for that reason the limit of carrying capacity of wires should be low. The matter was referred to a committee. The question as to whether the dynamo frame should be insulated or grounded provoked a lively discussion. Mr. Scott thought that in alternating plants insulating the frame was useless, and that the static charge might be a source of danger to the attendant from touching the frame, whereas a grounded frame would be a factor of safety; also that dynamos carefully insulated at the base were connected to the engine by wire-woven belts. Captain Brophy agreed with Mr. Scott. Prof. Crocker said that the static charge could easily be taken care of by grounding through a very high resistance or a wet string or a vacuum tube which would take care of the static charge, but leave the dynamo insulated. The attendant should always be protected by an insulated flooring or platform, so that he could not possibly be grounded while handling the machine. Next came the question as to what was high and what low potential. Prof. Crocker said that, as in some cases, 200-volt lamps were being used, and asked whether under the rules a three wire system carrying 400 volts between outside wires would be excluded and treated as a high-potential system. He thought the limit as to low-potential circuits could be just as well raised to 425 volts. Captain Brophy said the Western Union and several other companies used high voltage, and he found it necessary to distinguish between them and companies using heavy currents. On the question of substituting plain iron pipe for the iron-armoured conduit, everyone present favoured the use of plain iron, if they could be convinced that burrs and fins in the pipe would not strip the insulation. As to cut-outs, Mr. M'Devitt said that fusible devices were all wrong, and that fuses are not reliable by 100 or 150 per cent., while Captain Brophy thought the ordinary run of fuse blocks a delusion and a snare. Mr. Greene, however, said that the fuse had been unjustly condemned because the time element had not been considered; supposing a fuse would not go for five or ten minutes, the wire would not get dangerously hot in that time. Mr. M'Devitt remarked that the insulation might become charred. Mr. Jones raised the question whether resonance affected fuses; but Mr. Kennelly said that resonance never gave any trouble. The questions of switches and the advisability of doing away with ceiling rosettes were referred to committee. As to grounding the secondary coils of transformers, the English and Phœnix rules on this subject were read and discussed at length, and the whole subject was finally referred to a committee. On the subject of car wiring, Mr. Ford thought that under proper restriction lights and motors might be taken from trolley lines in places where no other electric power was available, but Mr. Merrill said that with the restrictions that would be demanded it would be better to instal an isolated plant, and under all the circumstances that it would be better to prohibit such work altogether. It was further decided to postpone the adoption of by-laws. It will thus be seen that nearly everything was referred and nothing was settled. The conference will meet again in June.

BOILERS AT ELECTRIC LIGHT STATIONS.*

There is a cause for everything, if not a reason. It is not always easy to see what the cause may be, or to be satisfied with the reason. But the fact remains. In electricity manufactories or electric light stations, whichever they may be called, it is noteworthy that steam is generated on a system different from that which has for half a century at least satisfied millowners, and indeed manufacturers of almost all known commodities. For ordinary manufacturing purposes the Lancashire or the Cornish boiler is used almost to the exclusion of all other types. The former is no doubt an excellent example of the survival of the fittest, and its all but universal adoption is the result of a careful calculation based on commercial principles. From the first, however, the Lancashire boiler has been almost absent from electric light installations. It is only recently that it begins to be used in a tentative fashion by electric light engineers. In not only the United States, but this country as well, we find that boilers of the water-tube or locomotive type are nearly always employed to drive electrical machinery. There must be some reason for this. We do not think that it has ever been stated; but it does not seem to be far to seek, and when found it is instructive.

When electric light stations were first designed in this country the designers were in almost every case electricians, not mechanical engineers; or at least not mechanical engineers possessing any considerable commercial knowledge of the working of steam machinery. These gentlemen knew from books that high-pressure steam was more economical than low-pressure steam, in the sense, at least, that a smaller weight of the former than of the latter would give a horse-power, so it was determined that high-pressure steam must be used. But the Lancashire boiler was not deemed suitable for pressures over 100lb., so recourse was had to water-tube boilers; and to locomotive type boilers because it was a familiar fact that on our railways pressures of 150lb. and more were regularly carried. It is no disparagement of the water-tube boiler to say that the results of its adoption have not been uniformly satisfactory. It is, for one thing, peculiarly exigent in its demands for good water, and in the second it is very expensive to keep clean, and if not kept clean the tubes split and leak. The locomotive boiler, again, is a very admirable steam generator, but it, too, has its peculiarities. It is the full consciousness of these things that has induced millowners to resist all temptation to use any other than the double-flued or Lancashire boiler, which has been recently so proportioned that it will carry any pressure asked for. Indeed, it should be almost self-evident that if a marine boiler 15ft. or 16ft. in diameter can carry a pressure of 160lb., there ought to be no difficulty in making a Lancashire boiler of half the diameter equally strong. The mistake committed by the electrical engineers has been in assuming that the boiler which made steam most readily, and was most economical in the consumption of coal, must be the best. It is just the species of error into which the non-commercial engineer is likely to fall. The truth is that coal represents but one item in the cost of making steam, and it is not invariably the most important item. The price to be paid for water is not infrequently very large; and even high-priced water may not suit either water-tube or locomotive boilers. Then there is the question of wear and tear, the quality of the steam produced, and many other matters which must all be considered before it is possible to say what is the best type of boiler to put down; and all this, be it noticed, has nothing whatever to do with the qualities of the boiler regarded from the theoretical point of view.

To make our meaning quite clear, let us suppose that a sum of £500 is available for the purchase and erection of a boiler. We may obtain with this a Lancashire boiler which will work well and give satisfaction for 10 years, with very moderate repairs, and be nearly as good and serviceable at the end of that time as it was at the beginning; or we may get a locomotive boiler which will need heavy repairs before half that period has elapsed, and will be good for very little at the end of the term. Or a water-tube boiler, which will last for half a century, simply because it has new tubes put in, a few at a time, all the year round, every year of its life. All three may be of equal evaporative efficiency, but even if they were not, the millowner would keep to the Lancashire boiler, not only because it would, in the long run, be much the cheaper of the three, but because it would always be ready when wanted. It would seldom, if ever, be laid off for repairs. No doubt it may be urged, and urged with truth, that both the water-tube and locomotive boilers are excellent steam generators. This does not affect the question in any way. All the experience available goes to show that over a series of years the Lancashire boiler will be found less costly in up-keep, and more trustworthy than any other type of land boiler in the market; and that this truth is gradually coming home to electrical engineers is demonstrated by the circumstance that recourse is now being had to the Lancashire boiler in very important installations, to an extent, indeed, not dreamed of a few years ago—that at St. Pancras, for example, which we illustrate this week. It must be understood that in writing as we do, we are simply bringing before our readers certain considerations often overlooked, and endeavouring to find a cause, if not a reason, for the remarkable departure from normal practice which marked the advent of the electric light in this country. It can scarcely fail to strike any thoughtful man as remarkable that types of boilers scarcely known in Great Britain should have been used to the exclusion of all other types for supplying steam to electric engines. Outside of railway shops no locomotive type boilers could be found driving stationary engines of more than a comparatively few horse-power. In factories they are practically unknown. The water-tube boiler fought for its life in Great Britain. All over the kingdom, in spinning and weaving mills, pumping stations, factories of all kinds, many rolling mills of the largest size, nothing was used but the Lancashire boiler. But with the new light all this was changed, and we had not only the electrical experiment, but the steam generating experiment as well, and it is not remarkable that the results were not always quite satisfactory.

It would not be fair, however, to attribute the adoption of the locomotive type or the water-tube boiler either to caprice or theoretical knowledge alone. No doubt installations were often constructed under circumstances that rendered it next to impossible to use anything but the water-tube boiler. There are places in the Andes where no part of a steam-engine or boiler must weigh more than 200lb. Everything has to be carried on mule back. There are places in great cities into which it is equally impossible to convey any large structure. For such places the sectional boiler is simply invaluable. But this scarcely suffices to explain the favour which the locomotive type of boiler enjoys. It is not because only such a boiler can be forced, and other reasons must be found for its adoption That it requires no brickwork and is an excellent steam maker are no doubt points very much indeed in its favour; but, when all this has been said and admitted, we have still to face the fact that for places where large demands are made for steam, day after day, nothing is so popular as the Lancashire boiler, or its modifications.

Those who can read the signs of the times know that the production of electricity on a small scale in numerous establishments will have to give way to its manufacture wholesale, on a great scale. That which has become possible at Beckton with gas may become equally possible with electricity. The question will then force itself on engineers, What is the best method of manufacturing steam? It is not wise to prophesy until after the event. Yet we are rash enough to say that probably the Lancashire boiler will be used in conjunction with mechanical stokers, the smallest possible amount of manual labour being employed. In settling this question it must not be forgotten that the demand for power becomes more and more uniform the larger the installation, and, consequently, the wider the district served. "The peak" does not occur, for instance, in all existing metropolitan installations at the same hour. This consideration will have an important influence on those who have to select the type of boiler to be used. Furthermore, the heat storage system introduced by Mr. Druitt Halpin may modify conditions of service very considerably. In saying this we do not wish, as we have said before, to be understood as finding fault with any particular type of boiler. Our object is to record what may be termed the drift of public opinion. It does not follow that we regard the water-tube boiler as inferior to the Lancashire if we state as a fact

* From the *Engineer*.

Digitized by Google

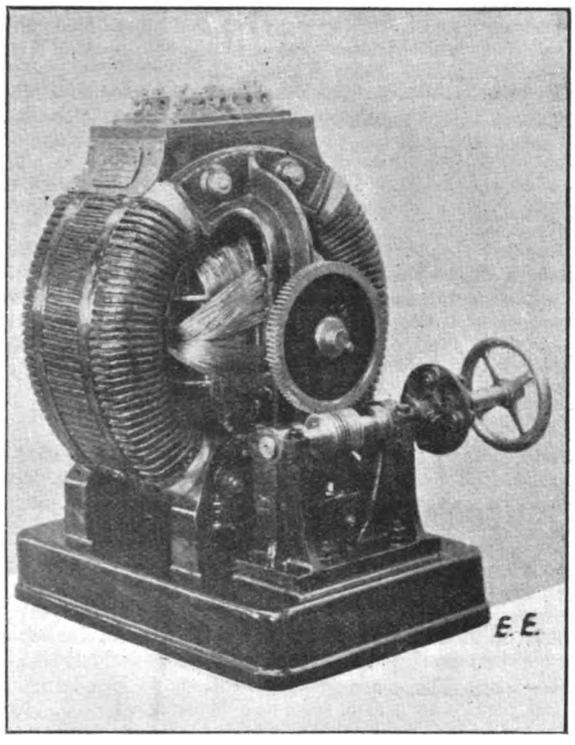
that millowners prefer the latter, and that electrical engineers in taking to the former have departed from precedent. The doubt and hesitation which exist are fairly well exemplified on a small scale at Islington, where Mr. Gay has put down both Lancashire and water-tube boilers almost side by side. It must, too, be borne in mind that nearly all the electric light stations in this country are comparatively young, and few opportunities have yet been afforded for testing the actual life of a boiler. Our purpose will have been served if we have succeeded in directing the attention of our readers interested in the manufacture of electricity to the fact that a considerable departure from normal manufacturing practice has marked the progress of the electrical engineer, and that many more things than the production of steam have to be thought of when ordering a boiler.

THE REGULATION OF PRESSURE AND THE REDUCTION OF LIGHT-LOAD LOSSES IN ALTERNATING-CURRENT SYSTEMS OF ELECTRIC SUPPLY.*

BY E. W. COWAN AND ALFRED STILL.

(Concluded from page 355.)

On the table we have one of the Manchester Edison-Swan regulators at work. The Manchester supply being a continuous



The "Manchester Edison-Swan" Regulating Transformer.

current, a motor alternator first converts it into an alternating current of about 20 complete periods per second. The alternating current supplies an incandescent lamp, and the regulator is so connected that the pressure at the lamp terminals can be raised or lowered by hand adjustment of the lever on the side of the case.

Compensators.—With regard to the means of indicating the feeding point volts at the station end, there are several methods by which this can be done. Pilot wires brought back from the feeding points to the voltmeters naturally suggest themselves in the first place, but there are objections to their use, of which the principal one, perhaps, is their excessive cost, especially when they are used in connection with long feeders. A very simple method of indicating what is the required pressure at the station end of the feeders in order that the supply at the far end may be independent of variation in load, consists in marking on the feeder ammeters a second scale of numbers—let us say in red figures—these numbers to indicate the required value of the station volts for any position of the ammeter needle. A step in advance of this, is a method which is more generally used in America than in this country. It consists in connecting the voltmeter in series with the secondaries of two transformers—a shunt transformer, T (Fig. A, Diagram 5), with its primary across the mains, and a series transformer, T 2, of which the primary is traversed by the main current. The secondary of this transformer being closed through an adjustable resistance, R, it will be readily seen that by suitably varying this resistance to suit the length and size of the feeder, the potential difference between the terminals, *t t*, may be adjusted to any particular fraction of the volts lost in the feeder. It follows that by setting this potential difference against the potential difference at the secondary terminals of the shunt transformer, the readings on the voltmeter will be an indication of the actual pressure at the feeding point. In Fig. B on the same diagram is shown the way in which this method of "compounding" the feeder voltmeter is illustrated in Dr. J. A. Fleming's book on "Transformers." In the text we read that "the E.M.F.'s of the two transformers are opposed to one another"; but this will not be the case unless the secondary of the series transformer is closed through a resistance, as in Fig. A. The secondary volts of the shunt transformer being in opposite phase to the primary volts, and the induced volts in the series transformer being approximately quarter period behind this main current, the two E.M.F.'s cannot be set against one another, and their sum must necessarily be greater than the value of any one of them.

Drop in Distributors, etc.—We have so far dealt only with the loss of pressure in the feeders and methods of keeping the volts constant at the feeding points. Beyond this the system must be self-regulating—that is to say, the loss in pressure between no load and full load must not exceed a certain definite amount. The amount of permissible variation at the consumer's terminals as fixed by the Board of Trade is 4 per cent. If, therefore, we proportion the distributors to give a maximum drop not exceeding 2 per cent., this leaves another 2 per cent. for permissible drop in transformers.

And here it may be as well to point out the disadvantage of specifying for transformers having a very small drop between

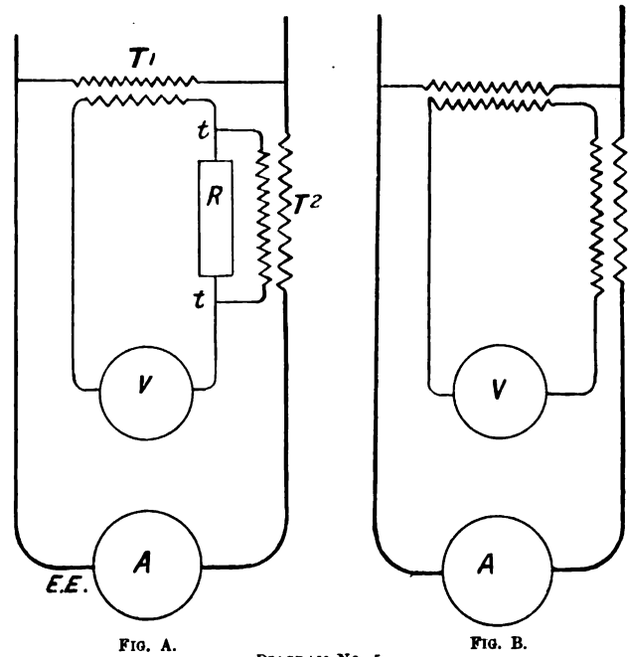


FIG. A. FIG. B.

DIAGRAM NO. 5.

no load and full load, without considering the effect of the drop upon the first cost and efficiency at light loads. It should always be borne in mind that for the same cost of material a transformer may be made to give either a small drop with a comparatively large iron loss or a fairly considerable drop with greatly reduced open-circuit losses. As an illustration in actual practice which bears out this statement, a few months ago we tested a transformer for which the makers claimed an unusually small loss at light loads. The tests proved that the claim was undoubtedly well justified, but at what cost? The drop on volts on secondary terminals between no load and full load was no less than 5 per cent. On the other hand, a transformer of the same output by another maker had an open-circuit loss nearly one and a half times as great, and this, although the weight of the transformer, and therefore the amount of material in it, was greater than the first one; but this greater iron loss was necessary in order to bring the drop within reasonable limits, the maximum variation being just within 2 per cent. In very small transformers it is difficult to keep the drop much below 2½ per cent.; a better regulation than this is rarely found in practice, notwithstanding specifications and makers' published figures. With regard to the drop of pressure in the house wiring, we believe there is very little that is new to be said on

* Paper read before the Northern Society of Electrical Engineers, March 23, 1896.

Digitized by Google

the subject. It should, however, be borne in mind in calculating sizes of wires that their effective resistance to alternating currents is always a little greater than when they are traversed by a continuous current. Mr. E. Hospitalier has worked out a very convenient table which will be found reproduced in the *Electrician* of January 12, 1894, and from which the increased resistance of wires to alternating currents for various diameters and frequencies may be easily obtained. It is perhaps needless to remark that this increased resistance is practically negligible except for wires, say, over ½in. in diameter, and comparatively high frequencies.

Before leaving this first section of the paper, it should perhaps be mentioned that a small regulating transformer connected in series with the low-tension wires entering the houses may be used for keeping the pressure constant within a fraction of a volt, notwithstanding variations in the supply at the consumer's terminals. One of these house regulators is on the able.

Reduction of Light-Load Losses.

There are few subjects of greater interest to the electrical engineer in charge of an electricity supply station than the question of light-load economy. The maintenance of a continuous supply cannot be avoided, but the cost of generation during the hours of light load is enormous. The waste—and no other word adequately expresses the loss which takes place—is not only in fuel, but in wages and capital. There is no occasion to define the lightness of the load during the small hours of the morning and the long hours of daylight. In the majority of electric light stations in this country the feeder ammeter needles rest persistently at zero. It is to such stations that our remarks will apply. An examination of the question shows us that there are perhaps four ways of meeting the difficulty: (1) installing accumulators which are charged during the hours of heavy load and employed during the hours of light load in driving a motor alternator of a similar kind to the one on the table, but, of course, multipolar; (2) by running a small and, therefore, more economical light-load plant; (3) by a gas-engine and gas-generator plant; (4) by adapting one of the smaller units in the station to work at a relatively high economy when lightly loaded. Below we deal briefly with these four methods.

Installing Accumulators.—Mr. J. C. Howell, supported by Mr. Crompton, endeavoured some time ago to persuade the members of this society that accumulators offered a means of saving many tons of coal per diem, even if they were only used as resistances for shunting the balance of current required to raise to full load the output of a steam dynamo. This startling assertion was accepted in many quarters, but we are unable to allow that accumulators can possess such a virtue. The question of their adaptability to alternate-current stations in conjunction with a motor alternator to effect economy becomes a difficult one to decide. The Bolton Corporation are putting this plan to a practical test, and we shall look forward to hearing at a later date some account of their experiment. It is a question of interest on capital outlay, depreciation and maintenance, on the one hand, against saving in fuel and wages, and also the undoubted advantage of being able at times to shut down the steam plant entirely, on the other.

Separate Light-Load Plant.—This is the plan which has found most favour up to the present time. One objection is its first cost, and another the frequent necessity for changing over from one plant to another, which, as it involves paralleling, needs the presence of a skilled attendant. This is felt most in the early morning in winter time, when the load is relatively heavy for an hour or two and a small plant cannot meet the demand.

Gas-Engine and Gas-Generating Plant.—At first sight, a gas-engine appears particularly fitted for this purpose, as it is theoretically an engine with a high efficiency at light load, on account of the gas consumed being proportional to the indicated horse-power. But there is another factor which influences the gas consumption—viz., the friction of the engine. In order to adapt a gas-engine to driving an alternator it must have two or more cylinders and a heavy flywheel, the consequence being that the standing friction losses are largely increased, thus seriously affecting the economy at light loads. The first cost of such a plant is, of course, much higher than that of a steam-engine of similar power.

Adapting One of the Smaller Units in the Station to Work at Relatively High Economy when Lightly Loaded.—We are fully aware that in recommending this plan as being the most effective and economical, we are laying ourselves open to considerable criticism, especially as some of the suggestions we shall make are in the direction of rather bold departures from present practice. But it must be remembered that in dealing with the difficulties of a low "load-factor" we must expect to be obliged to surrender some of our prejudices. The difficulties are peculiar, and may have to be met in a peculiar manner. It is impossible to deal with this subject without saying something about the many arrangements which tend towards economy at light load in the generation and transmission of steam. Time will not admit of the discussion of the different types of boilers. It is, of course, unwise to instal a small boiler for light load, and we do not suppose that anyone would think of doing so, but it does not seem to be generally so well known that a Lancashire boiler at any rate works at a much higher economy at quarter load than at full load if it is well lagged and carefully stoked. A boiler cannot have too much heating surface, though it can have too much grate area. With careful stoking, a consumption of 5lb. of fuel per square foot of grate area per hour in a Lancashire boiler will give a splendid evaporative performance of over 12lb. of steam from and at 212deg. F. per pound of coal, or 10 per cent. better than with a normal consumption of 20lb. of coal per square foot of grate per hour.

Economiser.—It might be thought that an economiser would not effect much saving at light loads, on account of the lower temperature of gases; but we have obtained an augmentation of temperature of the feed of 138deg. F. with a 96-tube Green economiser, when working a Lancashire boiler 30ft. by 7ft. at quarter load, and burning 5lb. of fuel per square foot of grate per hour. Prof. Kennedy has obtained an evaporation of 12·4lb. of water per pound of fuel with economiser, and 11·7 without, when burning only 6lb. of fuel per square foot of grate per hour.

Boiler Feed.—The wastefulness of steam feed pumps is well known, and in many stations electrically-driven pumps are now being fitted. Where the feed water is heated above 150deg. F. a feed pump of some sort becomes necessary, but in other cases injectors offer a means of feeding the boiler which is simple, inexpensive, and, we venture to say, economical. The three objections generally made against the use of injectors are unreliability, small range of regulation, and, lastly, that they are uneconomical. As to the first objection of unreliability, this is not borne out in practice so far as our experience goes, but a steam-pump as a stand-by should undoubtedly be erected. The second objection of the small range is easily got over by fixing three or four different sized injectors delivering in parallel into a common or "omnibus" delivery pipe. They work perfectly well in parallel, and in this way any required rate of feed can be obtained. The third objection of their being uneconomical is not, we think, a true one. Both in theory and in practice, as far as we have been able to ascertain, they are more economical than steam-pumps. As a pump pure and simple the injector is of course very inefficient, but energy cannot be extinguished, and it therefore follows that all the units of heat in the steam supplied to the injector are returned to the boiler, with the exception of the equivalent of the work done (the product of the volume of water injected and the back pressure), and a small loss due to radiation. It must, of course, be remembered that though all the heat is returned to the boiler, it is returned at a lower temperature—in fact, the live steam is used to heat the feed water from, say, 60deg. F. to 150deg. F., and this process violates one of the first conditions of economy. But compare it with an ordinary steam-pump; about 50 per cent. of the total heat in the steam supplied to the pump is rejected in the exhaust, to which must be added large losses due to radiation, and the more obscure losses due to reciprocation. It is difficult to compare the relative efficiencies of the one method which raises the temperature of the water from 60deg. F. to 150deg. F. by live steam, and from 150deg. to 320deg. in the boiler; and the method in which the temperature of the feed water is raised from 60deg. to 320deg. in the boiler; but common sense seems to point to there not being much difference between the two. The use of economiser or feed-water heater will of course somewhat alter matters, and each case should be considered on its own merits. Our firm conclusion is that an injector is the best light-load pump.

Steam-Pipes.—There are grave objections to supplying the light-load plant with steam from the main steam-pipe. This plant should be erected as close as possible to the boilers and supplied by a short auxiliary pipe of small diameter. It has been estimated that the radiated heat from every square foot of lagged steam-pipe costs 300lb. of coal per annum, and Prof. Kennedy has found that the amount of condensed steam from pipes, drains, etc., amounted in one station to from 8 to 9 per cent., and in another from 5 to 6 per cent. of the total weight of feed water.

Auxiliaries.—The economiser scrapers, centrifugal pump, and exciting dynamo must be driven during the hours of light load, and it is evident that if these are driven separately by auxiliary engines the result will be a serious waste of steam. We prefer to arrange for their being driven by the main day-load engine, using either belt, rope, or electrical transmission. As this engine is running in any case, its standing losses are not chargeable against the small extra power required, which can therefore be obtained at the very small expenditure of steam of about 12lb. per horse-power.

Condensers.—We unhesitatingly recommend the ejector condenser as being the most economical light-load type. No air-pump is needed, and thereby a substantial standing loss avoided. It is an absolutely reliable, cheap, and efficient piece of apparatus. The type with a means of regulating the adjustment of the nozzles is perhaps best suited to a variable load. The subject of the saving effected at light load by the removal of the standing loss of atmospheric back pressure by condensing

Digitized by Google

the exhaust steam has been so ably and fully dealt with by Mr. Willans that we do not propose to add any remarks of our own, excepting to say that it is by far the most important of the means we are bringing before you for the reduction of light-load losses. We show on Diagram No. 6 the saving of steam effected during the daytime at Altrincham by the use of an ejector condenser. The diagram shows the indicated horse-power below and the indicated horse-power above the atmospheric line on the morning of December 20, 1895. The indicated horse-power below the atmospheric line amounted to about 46 per cent. of the whole, or a saving of steam consumption of about 50 per cent., against which must be set the horse-power required for centrifugal pump, about 1 per cent. of the total horse-power of the engine.

Engine.—The discussion of the engine brings us back to our recommendation that one of the smaller units should be adapted to run economically at light load. A steam-engine runs very wastefully under these conditions, partly on account of its standing losses being practically constant at all loads, and therefore bearing a larger proportion to the power developed at light load than at full load, and partly on account of the steam distribution between the high-pressure and low-pressure cylinders being unequal at light loads. The latter point should be dealt with by designing the engine with an automatic cut-off governor which acts on both the high-pressure and low-pressure valves. In this way a fairly equal range of temperature in the two cylinders can be maintained at all loads. The cylinders should also be steam jacketed on account of the range of expansion being relatively great at light loads. Of the standing losses, the back pressure of the exhaust has already been dealt with, and the loss due to radiation can only be met by careful lagging of the cylinders and their covers. Lastly, there are the important losses due to engine friction and vibration. The only way of reducing these is by lowering the engine speed. These losses are so much per revolution, and if we lower the speed we reduce them in like proportion. We recommend that the speed should be reduced by about one-third, and that the governor should be so designed as to allow of an adjustment of its springs being made by hand,

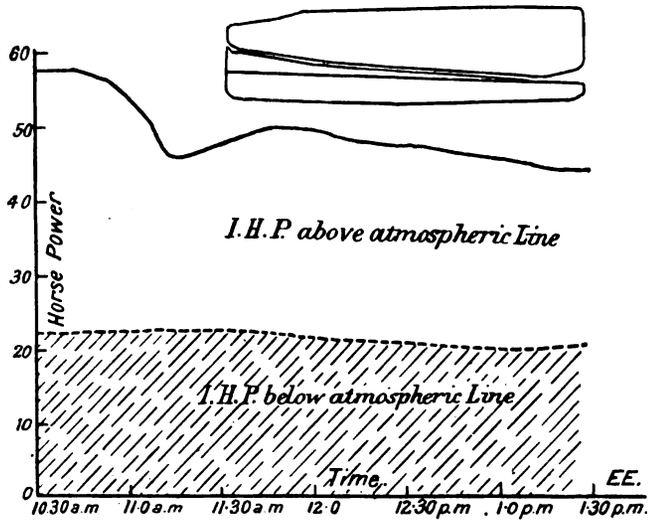

DIAGRAM NO. 6.

in order that the engine may be under its control at this reduced speed. As far as the engine is concerned there can be no doubt of the advantage of this plan; its effect on the electrical plant we deal with below.

Alternator.—The type of alternator which gives the highest efficiency at light load is undoubtedly the one having no iron core in its armature. But the reliability and mechanical strength of the iron-cored armature has so much to recommend it that it has found great favour, and we think rightly so, with central-station engineers. Probably the protection which the self-induction of the machine affords to the whole system in absolutely limiting the maximum current which it is possible to obtain from such an alternator, to only a harmless amount above the normal, has also done its part in placing this type in the position which it occupies at the present time. Engineers will readily sacrifice some efficiency and self-regulation to obtain such a "factor of safety" as the iron-cored alternator possesses. It must be remembered, however, that the eddy-current losses in an iron-cored armature are less at full load than on open circuit, a fact which was first, we believe, observed by Dr. John Hopkinson. We have recently made some experiments in connection with another matter in which this effect was very clearly marked. Apart from the windage and bearing friction, the hysteresis and eddy-current losses in an iron-cored armature when lightly loaded may be considerable. On account of the peculiar raking of the magnetic lines the iron losses in an armature for any particular values of the induction and frequency are greater than they would be if the same volume of iron were simply submitted to reversals of magnetism as in a transformer. The core losses in an alternator will increase approximately as the square of the induction; if, therefore, we could reduce the induction in the armature, a great saving of the all-day losses would be effected. For instance, suppose the armature to consist (as it often does) of two separate windings connected in parallel; by switching these in series during the hours of light load the induction in the core would be halved, and the iron losses consequently reduced to one-quarter of their former value, the losses in the exciting circuit being also reduced in the same proportion. Such an arrangement could not be worked without causing fluctuations in the light, but a little consideration will show that the same saving may be effected by the use of a step-up transformer. The alternator is excited to give, say, half its normal voltage, and its armature is connected in series with a transformer, wound to add the remaining half of the required volts. The loss in such a transformer will be very small compared with the saving in the alternator. All that now remains to be done is to make this transformer a regulating one, which will enable the volts added to be varied without any sudden fluctuations. The change of the alternator from a small-output machine to one capable of dealing with the full load it was designed for can

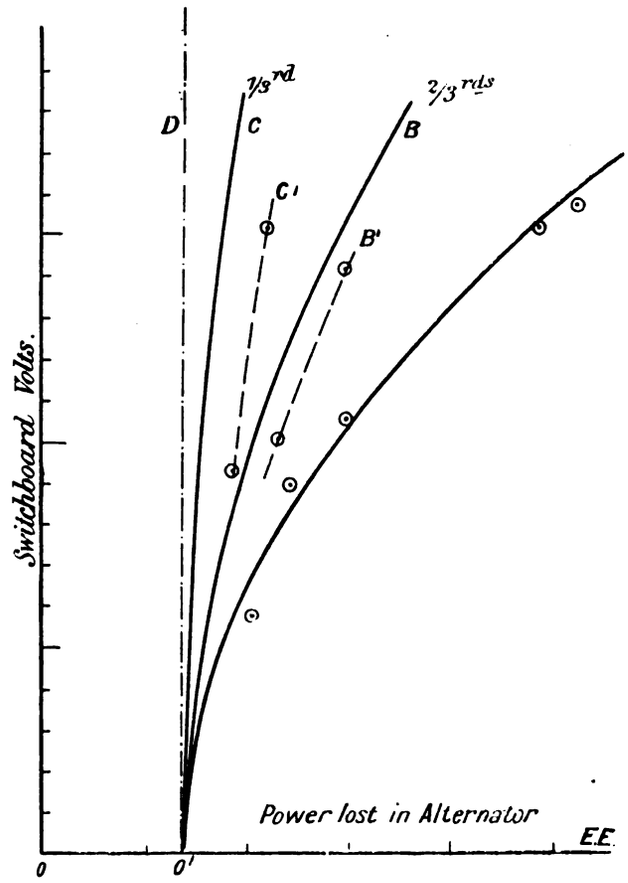

DIAGRAM NO. 7.

also be made without any variation in the light by simultaneously reducing the volts added by the step-up transformer and increasing the excitation of the alternator, as well as bringing up its speed, if this has been reduced as recommended when dealing with the question of engine efficiency. The capital outlay on such an apparatus would not in any case amount to much, but where regulating transformers are used for equalising the pressure at the various feeding points, as recommended in the first part of the paper, they can be without any difficulty adapted to do duty both as regulators of pressure and step-up transformers. The secondary must be wound with several separate windings, which, by means of a special switch, can be connected either in series or in parallel. By means of a simple interlocking device this switch may be so arranged that it can only be thrown over at a time when the transformer is in the position of no effect.

In Diagram No. 7 are plotted the results of some experiments which we have made on an iron-cored alternator in order to prove what has just been said with regard to the saving of alternator losses. The alternator was driven at constant speed on open circuit by means of a small continuous-current motor, and readings were taken of the power supplied to the motor for various inductions in the armature. In the diagram the vertical distances are proportional to the volts as read on an electrostatic voltmeter, and the horizontal distances are proportional to the power supplied to the motor, a correction being applied for the losses in the motor itself. The distance, O O_1, represents the losses in windage and bearing friction; it is the power required to drive the alternator with

Digitized by Google

the field magnets unexcited. The curve O_1 A is a parabola, the distance of any point on the curve from the vertical line, O_1D, being proportional to the square of its height above the horizontal datum line. The points enclosed by the small circles are the results of the experiments, and by their agreement with the curve O_1 A serve to show that, in assuming the iron losses in the armature to be proportional to the square of the induction, the error—if any—is very small. The curves O_1 B and O_1 C are also parabolas, but for equal ordinates the horizontal distances from the line O_1 D are respectively four-ninths and one-ninth of their value for corresponding points on the curve O_1 A. These are the curves which would be obtained by connecting the secondaries of the step-up transformers in series with the armature circuit, on the assumption that the losses in the transformers themselves are negligible. In the case of curve B the alternator generates two-thirds of the full volts and the step-up transformer supplies the remaining one-third. Two experimental readings were taken, through which the curve B_1 has been drawn. These readings, of course, include the losses in the transformer. The dotted curve, C_1, was obtained when the alternator generated only one-third of the total volts. In this case, as will be seen by inspection of the diagram, the step-up transformer absorbed rather more power than in the previous experiment. Indicator diagrams of the horse-power of the engine showed the same saving.

In conclusion, we must deal with the effects of the alteration of frequency which result from the reduction of speed by one-third. In the first place, the hysteresis losses in the transformers are increased by about 25 per cent., while the eddy-current losses remain approximately the same. As the C^2 R losses are small when the load is light, the resulting temperature will not be abnormally high. The question therefore naturally arises as to whether the saving in the engine is not made up for by the increased losses in the transformers. The best answer to this question is to give you the result of a careful experiment made at Altrincham. In this experiment the speed of the engine was reduced from 350 to 246, and the saving in the indicated horse-power was 16·1 per cent., which is equivalent to a saving of 17 per cent. with a reduction of speed to two-thirds full speed. It must also be remembered that at Altrincham the transformers are for the most part fixed on consumers' premises, and are therefore of small size. Under ordinary circumstances, with large transformers the saving should be at least 20 per cent. The effect of the alteration of frequency upon the meters is not serious. If Thomson meters are used, the error for a third reduction is practically negligible. With Shallenberger and Hookham meters it amounts to from 1½ to 5 per cent. We have made experiments on these meters the results of which are plotted on Diagram No. 8. In this diagram the horizontal distances represent the frequency, and the ordinates show the variations in the readings of the meters. Vertical lines are drawn at the points of normal frequency and at a third reduction. Curves are drawn for both full load and a third full load. As to the effect of the reduction of frequency upon arc lamps and alternate-current motors, there is little to be said. Our experience is that the effect upon the ordinary commercial arc lamp is not appreciable, and it will be time to consider its effect upon motors when they come into practical use.

We have endeavoured in this paper not only to make recommendations, but to support them as far as possible with figures ascertained from actual practice or experiment. We hope that some of the members present who have charge of central stations will be able to give us the result of their experience both with the difficulties of regulation of pressure and light-load economy.

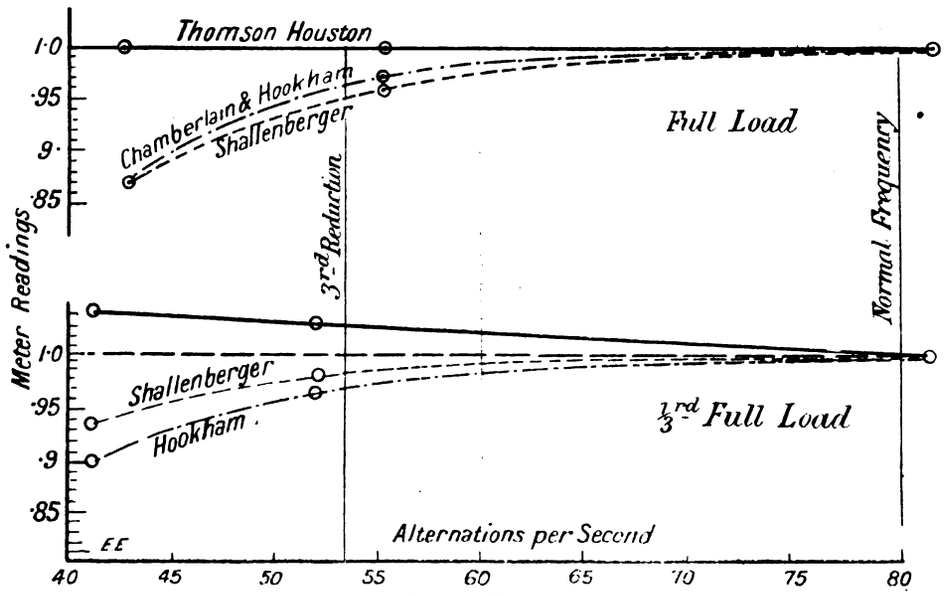

DIAGRAM No. 8.

DISCUSSION.

Mr. Rider said he should first of all say that he had listened to that paper, and read it, with deep interest, and that it was one of the most interesting papers they had ever had before them. He said that without any disparagement to any they had had. So far as the first part of the paper was concerned in dealing with the regulation of pressure, he was fully in accord with the authors. In the "Thomson" diagram the size of the feeder which worked out most suitable for that particular current came up to $^{19}/_{14}$. Taking the maximum current at 71 amperes which was given in the paper, that came to about a density of 750 amperes per square inch, which was a very safe working current for a feeder. He fully agreed with the statement that the size of the feeder should be determined by the current it had to carry, and that the drop should not be taken into account at all, as by the Thomson law the loss per mile due to the drop increased in the same ratio as the cost of the feeder. With regard to the regulation of the feeders, the method the authors had drawn their attention to was one which he (the speaker) was at present using, and he could speak of it in the highest degree. He would like to point out that it was only applicable and could only be used to keep the pressure at the feeding points absolutely constant when the different feeders and networks were distinct from each other. If they had one network and two feeders feeding at different points, they could not keep the pressure exact at those two feeding points under such conditions. They would have to cut the network, each feeder would have to serve its own network and not be connected with any other. Then they came to the second part of the paper. He was afraid that there was a good deal of debateable matter in it. A scheme which he himself was putting down had been mentioned—that was of using accumulators in connection with a motor alternator. He was not at present able to give any figures because they had not started, but the society must get his successor to give them a paper, and he would no doubt tell them more truth about it than he (the speaker) would. The various points brought before them wanted very carefully thinking about. It was recommended that for a light day-load plant a separate steam-pipe should be used. He presumed that it was meant that the main steam range should be cut off during the day. If they turned the steam on suddenly to a large steam-ring they ran the risk of breaking the joints. He believed in having steam on right up to the stop-valves of the engine the whole of the time, otherwise they might have a big smash. The scheme which was brought before them for reducing light-load losses was, no doubt, very interesting, and the figures which were given were very plausible, but he could not altogether see through them. The authors mentioned that they found a saving of 17 per cent in the horse-power when running through this augmentator, having the engine speed reduced two-thirds—that was 17 per cent. of saving; it was not 17 per cent. of the full horse-power of the engine. Supposing the engine was 100 h.p., it was a very bad plant if it took 20 h.p. to drive it at full load. If they took 17 per cent. of the 20 h.p., it only brought them to about 3·4 h.p., which was not a very great saving. He thought the best way would be to put in a much more efficient plant—say, an open-coil alternator with no iron in the armature—rather than using one with heavy losses. Surely, if an alternator with no iron in the armature was awkward to run parallel with the iron-cored machine which they had at heavy load, the difficulty would only come in at the time of paralleling to change over, as the small plant could then be stopped. It was suggested that the governors of the engines should be arranged so that they would give the variation of speed mentioned. He wished to see the governor which would enable them to

Digitized by Google

alter the ratio one-third and still have a good range of governing. He thought if they had governors which would give an adjustable range of 5 per cent., they were good governors. This method of reducing losses only took into account the losses at the station, and did not affect the outside losses. In fact, they were going to increase the losses outside, and when their station became a large one, and the number of transformers very large, that method would be in a still worse place, because heavy losses would be going on all the time outside. With regard to the question of altering the frequency of arc lamps and meters, last year at Bolton they reduced the speed of the whole of the plant 17 per cent., not on account of the alternators, but for reasons which were purely mechanical. They brought the periods down from 100 per second to 83 per second. They had a number of arc lamps in the town, and they had not to alter the regulation of a single one—in fact, they burnt better. With regard to the meters, some of the meters were made for 100 periods, and he thought that some of them would be reading a bit out at the reduced periods. He made careful tests, and put in series with these meters other meters specially made, and he found practically no difference at the end of the quarter, taking the ordinary working load on the meters. They were Chamberlain and Hookham and Shallenberger meters. The paper said that as there were no alternating-current motors in use they need not be taken into consideration. He (the speaker) said alternating motors were in use in many stations, and if a station had only one motor in use the result of such a procedure as lowering the speed of the plant every day would be to damn the system.

Mr. Mordey, before speaking on the paper, wished to be allowed to say a word of explanation. In the report of their last meeting he read that the president had done him the honour to regret his absence, and that the author of the paper, Mr. Hammond, did him similar honour. The fault was scarcely his. He was not a member of the institution; he had had no notice of the meeting nor copy of the paper, either from the society or from the author; nor had he been invited, so that he could hardly have been expected to be present. With regard to the matter before them, he wished to join in congratulating the authors on the paper, which was an excellent one; he wished they had more such papers in London. They did not get as many of them as they ought. A great many points were touched on, but he must confine himself to a few of them only. With regard to the first paragraph, he quite agreed with the plan the authors advocated, and which was shown in Fig. 4; it was a very good one, and one which in many cases had advantages. The Brush Company used it a great deal; he thought it was Mr. Dawbarn, of his company, who first introduced it, and they found it convenient and simple. Ideas as to "banking" transformers had changed, they did not get very much advantage if they used transformers above a certain size. In a 12 or 15 kilowatt transformer they got a no-load loss of between ·75 and 1 per cent., and, no matter how large the transformer might be, the loss did not go much below that, so that there was no advantage in efficiency in having very large ones. And as to cost, the lower price per kilowatt of larger transformers had to be set against some extra cost in mains and inconvenience in handling. It might be hypercritical, but he wished to object to the capacity current being spoken of as being in advance of the E.M.F. He knew it was the universal way, but it was wrong, and it gave a wrong impression. The ordinary, or, he might say, the general explanation given of the difference between self-induction and capacity was that self-induction caused it to lead or to be in advance of the E.M.F. He once heard an eminent professor explain that self-induction was something that when the E.M.F. was applied delayed the flow of current, while capacity was something which sucked the current out before the E.M.F. was applied. This amounted to saying that the effect preceded the cause. In the interests of clearness of perception of the physics of the matter, he wished to protest against this way of speaking of the effect of capacity. What really happened was that the current was caused to lag still more by capacity than by self-induction; the capacity current lags so much behind the wave of the E.M.F. producing it that it was just in front of the succeeding E.M.F. wave. For mathematical purposes it might be convenient to consider it as in advance of the E.M.F., but it must be remembered that that did not correctly represent the fact. Instead of saying it was a quarter period in advance of the E.M.F., it would be physically more correct to say that it was three quarters of a period behind the E.M.F. The authors alluded to an excellent method of regulating shown in the various diagrams (3 and 4) He thought that the arrangement of the Manchester company or of Mr. Rider was an excellent one. It did not differ in principle from what had been seen before, but he thought it was the most practical way of applying the principle With regard to the saving of power when the pressure was raised by apparatus of that sort, he might mention a fact from his own experience. In one station with which he was acquainted it was necessary to raise the volts. He found on going into the question as to whether there would be a loss of power, that there was a saving of power. He found that by raising the volts by an augmentator, the actual power absorbed by the alternator and the augmentator was less than by the alternator alone, if worked up to the full E.M.F. He mentioned that as illustrating the effect of the apparatus, which was called a "hitcher-up." There was another point in connection with "hitching up" which was perhaps of some interest. There had been a good deal of discussion as to whether they ought to have self-induction or not in alternators. He had always thought the less they had of it the better; if for no other reason, for the very sufficient one that it spoiled the "characteristic" of a machine and made regulation troublesome and difficult. When it was working normally there was no need for self-induction, but there were perhaps certain abnormal conditions under which self-induction might be of service if the required effect could not otherwise be obtained. For example, if they had two alternators without self-induction and put them in parallel when they were out of phase, a more or less violent shock occurred. If they had attempted to lessen the shock by giving the machines a good amount of self-induction, they would lessen the shock, but the machines would regulate badly; they would have a large drop in the E.M.F. when the load was increased. With an augmentator, however, with the fine wires across the mains and the thick wire in series with the alternator they had self-induction, but it was only self-induction when the machines were out of step. At other times it had no effect on the regulating qualities of the machine. This was a valuable feature, in his opinion, in connection with the use of augmented alternators. An important matter was raised by the proposals to reduce the losses in alternators at light load. He rather agreed with Mr. Rider's criticisms on the proposals. He thought the whole point of the Diagram No. 7 was that the machine was an unfortunate one for the purpose. He did not mean to say that it did not illustrate the proposal well, but he was quite sure that the authors would not put it forward as a machine that had other good qualities than that of showing the need for reducing its load losses. He was rather in favour of reducing the engine losses at light load than the alternator losses. Of course, engines should not be run with very small loads; but in cases where it was necessary, he thought that the losses of even a large alternator were so small that the probability of using a small engine should be considered in connection with some clutching device by which the alternator would be driven in the daytime by a small engine and at night by the large one. He might illustrate what he said about the careful lagging of the cylinders by referring to a recent experience he met with when carrying out a test. As the people who built the engines were very anxious to get good results, they had every door and window closed. He was assured by the man in charge of the engine that if they had the doors and windows open there would be a very perceptible increase in the amount of fuel consumed. He suggested that they might put the engine into the feed-water tank so that the lost heat might be recovered. Upon the subject of alternators he should have liked, had there been time, to have said a good deal. He thought it was a mistake to suppose that with a machine without iron in the armature they got such a very large current on short-circuit. As a matter of fact, the current on short-circuit with an armature without iron in it was not, nor need not be, more than with machines with iron cores. In his own machines they always short-circuited the terminals with full steam on, and the current usually did not rise above three times, and he had never yet seen it more than five times the full working current. They had learned by experience that they must make machines to stand short-circuiting, and had had no difficulty in doing so without losing the good regulating quality which he thought, next to safety, was of prime importance to central-station engineers. The first thing to have after safety was a machine with the smallest possible fall of potential and self-induction. Just one word before he concluded on the subject of reducing speed. If the authors would consider that the light-load dynamo under most circumstances was running a large number of transformers, and was fairly heavily loaded, even with no lamps on, he thought that they would see that a reduction in the speed was not advisable, because the total transformer loss would increase more rapidly than the alternator loss would diminish This would be the case at least in stations where the day-load dynamo and engine were fairly proportioned to their load.

Mr. Statter said he had very little to say except that he must congratulate the authors on the paper. With regard to the Diagram No. 2, he would like the authors to tell him why they limited the money to be spent on the feeder to the copper. It seemed to him that they ought to be able to spend as much per annum on the losses in their feeders as they incurred by way of interest on the total sum expended in materials and in the labour for laying the same, plus an allowance for depreciation in getting the current from point to point. He supposed that in central-station work it was a very difficult matter to fix upon the size of the conductor, because they did not know what the requirements in the future would be. But if Thomson's law was used at all, then 10 per cent. (the authors' figures for interest and depreciation) of the total cost of the feeder and of laying it should be plotted, instead of 10 per cent. of the cost of the copper and insulation only, as plotted by the authors. In 1882 or 1883, Mr. J. E. H. Gordon was carrying out an installation at Paddington for which Messrs. Crompton supplied certain apparatus, and he (Mr. Statter) was then a pupil with that firm and it was he who informed the authors of the use of the term "hitcher-up." He was not quite sure who did the christening, whether it was Mr. Gordon or Mr. Kapp, but it was one of the two. He thought that the idea of augmentation was transmitted to Mr. Kapp, and was really due to the late Mr J. E. H Gordon alone.

Mr. Wordingham said he did not wish to take up much time, as he was afraid the authors of the paper were getting tired of being congratulated, but, if they would allow him, he would like to say that it was certainly one of the best papers they had had. Its terseness, clearness, and practical nature were very striking. The first point he wished to refer to was with regard to the fourth method of distribution described in the paper. He thought the authors were certainly right in saying that it was the most convenient and best way of distributing; at the same time, in case of a short on the mains, all the fuses might go, and it would be a terrible nuisance to get them back quickly, and there would be a very serious interruption in the supply, whereas if they had had

Digitized by Google

the transformers in sub-stations they could very rapidly get their fuses replaced. He thought the position the authors had taken up about the most economical size of feeder quite unassailable. The current density which had been worked out in that diagram was about what he believed to be the best density they could find. It was about 750 amperes per square inch, which agreed fairly well with his own practice; he generally used 600 amperes. With regard to the device for showing the potential at the end of a feeder, which the authors said was largely used in America, he believed that that was due to Dr. John Hopkinson's method being introduced, and patented by him many years ago. He thought that that might be of interest to mention, as they did like to get their ideas from America. The same consideration that occurred to Mr. Rider about the steam-pipe occurred to him also; he did not think it was really practicable to shut off the main steam range for any part of the day, unless they were sure to have ample time to have it on again. If they had a sudden demand, and the range was shut off, the result would be disastrous. He might say a word with regard to the reliability of the ejector condensers. At the Manchester station they had them on all their engines, and they had never had the slighest trouble with them, and they had given excellent results.

Mr. Nisbett said he would like to protest against Diagram No. 2, which in his opinion was entirely misleading, owing to the fact that the cost of laying the mains, armouring, making good the pavement, etc., had not been included. It was obvious that because these were standing costs, whatever size of mains they laid, they should not be left out, for when the main was worn out, the armouring was worn out, and the trench was also worn out, and therefore depreciation on these should be added to that on the cable. This allowance would make the economical current density very much higher than the authors supposed. Taking the same example as the authors had done—viz., an average current of 26 amperes—to the cost of the cable must be added that of the armouring and trenching; the economical section of copper would then be ·03in. instead of ·1in., so that at load times that cable would be working at a density of 2,500 amperes per square inch. The authors, on the other hand, had taken the cost of energy lost in the cables at 1½d. per unit, whereas they had also taken the energy lost in driving the pumping and other plant at something like ¾d. per unit, because they said the standing costs were not in such case chargeable. Of course the same reasoning applied equally to the losses in the mains, it being only the coal bill which was increased. If now they add to the interest and depreciation on the cost of the cable the amount due to the trenching, armouring, etc, and reduced the cost per B.T.U. lost in the mains to ¾d. instead of 1½d., it was at once obvious why Thomson's law was not more generally adopted, at any rate for high-tension mains, for the law showed that the economical section was such that if it were used the mains would be red hot at load time every evening. There were one or two points in connection with the system of distribution marked D (Diagram No. 1). He could not altogether see that it had many advantages over the system C. Mr. Wordingham had raised a point about the difficulty of getting at fuses in transformer pits. That was a very important one. The contacts on transformers were very apt to get loose. He considered the scheme with sub-stations far preferable. All the contacts could be seen and examined periodically with ease, and the facilities for switching transformers in and out as the load varies were better. Both systems, however, had their uses. Then the authors laid too much stress altogether on the amount of capacity current. They calmly talked about a capacity current of 10 amperes on a feeder. That would mean that the feeder would have to consist of 25 miles of $^{19}/_{18}$ cable. He thought that they had put down to the cables that which belonged to the transformers. He agreed with the authors as to the necessity for regulation on feeders, and the apparatus designed by them seemed to answer its purpose admirably. With regard to the remark as to the cost of pressure wires, these are not so great as the authors seemed to think, as a pair of pressure wires can be put into a high-pressure cable for about £35 per mile, which was not a very serious item. He did not agree with the authors as to the economy of injectors. He thought that they rather contradicted themselves as he had read it. Apparently they had overlooked the losses due to the condensation of steam and the necessary re-evaporation of the water; the pulsometer pump was an instance of that, and although a useful form, he did not think anyone would say it was a more economical form than a barrel pump. It seemed to him that a good pump of the ordinary type driven by an electric motor was far and away better than any injector.

Mr. Heaketh said he thought that engineers at last saw the futility of seeking for an absolutely uniform day load, and the authors were now attacking the question at the right end in seeking for high efficiencies at low load instead. Certainly any central-station engineer who settled down to solid work after hunting the phantom of a day load would find that those little economies were very difficult to obtain, even more difficult perhaps than the day load. With regard to the question of boiler efficiencies, the efficiency of a boiler increases as the duty was lowered. He obtained about 9·5lb. of water per pound of coal when evaporating 9,000lb. of water; but reducing the evaporation to 6,000lb. of water, he got 10½lb. of water per pound of fuel, showing a great advantage from not pressing boilers, or using rather large boilers for low duty. As to cutting off the steam range, he found that the losses in the steam-ring were getting very considerable, and tried the natural expedient of cutting it off during light-load time, but, unfortunately, the cost of repairing joints was double the cost of keeping the steam up. There was also a great deal of loss in the use of feed-water heaters. It was a very common practice to put a large feed-water heater in the main exhaust-pipe, and to expect that they were going to get the full advantage of the whole of the heat units in the exhaust steam. That was a very great fallacy. The same economy would be obtained by using the exhaust steam from their pumps to heat the feed water, and condensing the main exhaust. If they so used the exhaust of their steam-pumps, the losses in driving feed pumps by steam were not so great as they would at first appear. The steam taken by the centrifugal pump mentioned by the authors would not be 1 per cent. of the total steam taken by the engine, although its power might be 1 per cent., but the steam would be something between 5 and 10 per cent. The method of reducing engine losses by reducing the speed was rather drastic, and he would rather use an alternator without iron in the armature. They had one or two motors at Blackpool, and to alter the periodicity every day would cause such trouble that they would have no peace at all. One of the greatest requirements in central-station working was absolute confidence of the consumers in the supply, and if they were going to vary their speed every day, of course the consumers would never put up with it. As regards the low-tension distribution in scheme D, he said that they had experimented with short-circuits recently at Blackpool to see the effect, and found that the fuses acted immediately, and cut out the faulty section.

Mr. Lindley said that, on the question of the reduction of the speed, he thought that, apart from the difficulty which Mr. Rider had foreshadowed with the springs, there was the difficulty that they would have to stop the engine to alter them again before it could be put in parallel with the machines. He would like to suggest what might be done to meet that difficulty. It was not advisable to reduce the speed of the engine providing they could put up with having the alternator running at full speed. The whole thing really centred on how much they could reduce the power of a compound engine without seriously falling off in the economy. This in a suitable engine should be one-fifth of full load, and then there would be no necessity to reduce the speed of one of the smaller units in order to operate the day load with economy. He might suggest to Mr. Mordey, who had been kind enough to offer to teach them something about putting engines into feed-water tanks, that he, Mr. Mordey, might have put the steam-pipes in also, so that they would get a higher efficiency still.

Mr. Still, in reply, said that Mr. Cowan and he had been prepared to meet with a good deal of opposition, as there was no doubt they had laid themselves open to attack from various quarters. The way in which the paper had been received was a very agreeable surprise, and he wished to thank those present, both on his own and on Mr. Cowan's behalf, for the kind way in which they had spoken of it. He proposed to reply to the points raised on the first part of the paper, and Mr. Cowan would then deal with the second portion. He was glad to learn that Mr. Mordey had found the system of distribution shown at D in every way satisfactory; it certainly seemed to him very superior to the system of sub-stations with a heavy low-pressure network, which neither from the point of view of economy or of regulation made proper use of the many advantages of a high-tension supply. With regard to Mr. Wordingham's remark that in the case of a short-circuit all the fuses might blow, this was only applicable to the case in which all the secondaries of the transformers were connected in parallel by closing the switches marked S, which would most decidedly be the wrong thing to do. In reply to Mr. Statter, and notwithstanding Mr. Nisbett's great confidence in his own assertions on the subject of Thomson's law, it was quite evident that in working out the most economical cross-section for a feeder, the capital cost they had to consider was only that portion of the total capital outlay which depends upon the amount of copper in the feeder. Mr. Nisbett admitted that the laying of the mains, making good the pavement, etc., were standing costs and did not depend upon the size of the cable, and that was the assumption which had been made in the paper; but Mr. Nisbett still thought that the amount of those costs should determine the size of the feeder. Why, then, should he stop at the culverts and trenches and not include transformers and sub-stations, or even the cost of the generating station itself? The wearing out of the culverts or pipes and the cost of keeping them in order was a question of the choice of the system, not of the exact cross-section of the cable to be used. If the extra labour of drawing in a heavy cable was worth considering, it should undoubtedly be taken into account, as also should be the increased cost of the culverts, etc., if they had to be made larger in size as the cable increased in weight. The most convincing argument of all in support of their contention that these capital costs which were constant could not affect the economical side of the cable was one which every mathematician would appreciate at once. In order to obtain the minimum value of any quantity which was a function of another variable quantity he differentiated both sides of the question, and since the differential coefficient of a constant was zero there could be no trace of that constant left in the differential equation, and it was therefore quite impossible that it should influence the size of the feeder. Mr. Nisbett mentioned excessive temperature rise as a possible limit to the size of feeders worked out on Thomson's law, but in practice that was not found to be the case, and for that reason it had not been referred to in the paper. If a dangerously high temperature was likely to occur at times of full load, two or more cables would have to be laid side by side, or the cross-section of the single cable increased, according to which method proved to be the most economical. Mr. Nisbett also spoke of feeders as being buried in the ground, but this was bad practice; they should be always drawn into pipes or laid in culverts, where they were easily accessible and could be added to when

Digitized by Google

required. With regard to the 10 amperes of capacity current referred to in the paper, that was merely assumed in order to work out an example, but as a matter of fact a capacity current of eight to ten amperes, or even more, was by no means impossible or unheard of; and Mr. Nisbett seemed to forget the existence of rubber-insulated cables, which, with their thin dielectric of comparatively high specific inductive capacity, took far more capacity current than paper-insulated cables. The current due to the capacity of the cables was a totally different thing to the magnetising current of the transformers, and there could be no confusion between the two. Mr. Mordey, on the subject of capacity current, objected to its being spoken of as a quarter phase in advance of the E.M.F. This, however, was the usual way of expressing what was really the truth, and the question was, after all, only one of choice of terms. There were undoubtedly two ways of expressing one and the same thing, and it was, of course, quite correct to speak of the current as lagging three-quarter phase behind the E.M.F., but when dealing with the phase differences between two periodically varying quantities, there was no beginning and no end to be considered; and the displacement of one of those qualities with regard to the other could surely be expressed with equal accuracy either by stating the amount by which it was in advance of the other, or by the amount by which it lagged behind.

Mr. Cowan, in reply, said that Mr. Rider, Mr. Wordingham, and Mr. Nisbett had all criticised the suggestion that steam ought to be cut off the ring-main during the hours of light load, as they did not believe it was practical on account of the failure of joints likely to arise. If that was the case, why was it that cylinder-cover joints did not give similar trouble? He thought that if the joints were properly made and the steam-pipes properly suspended, such trouble ought not to occur. Of course, great care must be exercised in admitting steam to a comparatively cold range of pipes in the matter of draining, etc. It could not be done in a hurry. There seemed to be considerable doubt in the minds of many of the speakers as to the advisability of reducing the speed of the engine. Mr. Mordey and Mr. Lindley seemed to think that the object was to save losses in the alternator. That was not so; the saving effected was only in the engine; nothing was saved in the alternator. A good deal was made of the increased losses in the transformers which would, of course, arise with the lower frequency. That point had been, he submitted, effectually answered in the paper. When the time came when the day-load plant was loaded with a very large number of transformers, the only saving in the reduction of speed might be in wear and tear, and it might not be considered worth while to continue the practice. He did not think there would be any great difficulty in designing a governor which could be adapted to control the engine at two different speeds. The tension of the springs should not be altered, but the leverage at which the weights acted; and the alteration must, of course, be made by hand without stopping the engine. Mr. Lindley preferred an engine which gave nearly equal economy at all loads, from one-fifth to full load. But the question was not one of thermodynamic efficiency only, but brake horse-power compared with steam consumed. An engine which gave nearly equal economy at from $\frac{1}{5}$ i.h.p. to full load was the right kind of engine to instal for light load; but the saving due to reduction of speed was effected with that engine as well as with any other. On the question of the results of the reduction of frequency from the consumer's point of view, the only point raised was the effect upon motors. In reply to that, he would only say that he held the opinion, and always had held it, that motors were unfit for lighting circuits, especially alternating-current motors, with their large idle current. He prophesied that if motors became popular, the electric light would become unpopular. It was impossible to regulate properly with alternating-current motors on the circuits. Having come now to the proposed method of reducing the alternator losses—viz, by halving the induction—he was glad to have Mr. Mordey's support as to the saving being an undoubted fact. At the same time, Mr. Mordey had misunderstood Diagram No. 7, the curves on which were drawn to show that the losses in alternators varied nearly with the square of the induction. The plotted experiments were made with an iron-cored alternator, but experiments with Mr. Mordey's own alternator would follow the same curves—indeed they would proximate more nearly to the true parabolas drawn, because the hysteresis loss peculiar to an iron-cored alternator did not vary quite as the square of the induction. The objection to Mr. Rider's suggestion of putting an alternator down for light load which had no iron in the armature was chiefly its first cost. They thought it important to save the first cost and space occupied by a special light-load plant. Mr. Rider seemed to think that 3·4 h.p. was hardly worth saving (it was more than that); but even 3 h.p. or 4 h.p. for 16 hours a day for 365 days in the year cost an appreciable amount, and was certainly worth saving in a small station. Mr. Mordey said that it was possible to design his alternator to give on short-circuit no more current than an iron-cored. Quite so; but what then became of the characteristic? It was possible, also, to design an iron-cored alternator with as good a characteristic as Mr. Mordey's—at a price. Mr. Nisbett thought that they had overlooked the losses in an injector due to condensation of steam. He thought Mr. Nisbett had hardly done justice to the remarks made under that heading in the paper. They had given a great deal of consideration to the whole subject, and had come to the conclusion that nothing but careful and authoritative experiment could settle the point. They had looked up crowds of reference, but had been unable to find any reliable results of experiments. He would ask Mr. Nisbett to reconsider the question, bearing in mind that all the heat in the steam went back into the boiler. Mr. Still had replied very fully to the criticisms of Thomson's law, but there was one point. Mr. Nisbett contended that if $\frac{3}{4}$d. per unit was taken as the cost of energy consumed by the auxiliaries, that 1$\frac{1}{2}$d. ought not to be taken when considering the effect of the losses in the mains, but $\frac{3}{4}$d. The two problems were, however, entirely different. In the first instance the question to be settled was whether to drive the auxiliaries by the main engine. The main engine was running in any case, and therefore, for the purposes of comparison, its standing losses would not be taken as chargeable against the auxiliaries; whereas the standing losses of a separate plant must be—that was surely good logic. But in the case of the losses in the mains the problem was different; there was no alternative to consider, and all losses, as in meter shunt, transformers, mains, etc., should be charged at the full works cost, including fuel, oil, wages, etc., based upon the output registered by the station, not the consumers' meters.

Mr. Fawcus, in rising to propose a vote of thanks to Mr. Cowan and Mr. Still for their paper, said he would just make only one remark about the steam-pipes. He was rather surprised to hear Mr. Rider and Mr. Hesketh tell them that they could not keep their steam-pipes tight, and he pointed out that there were thousands of plants where the steam was shut off every day, and if electrical engineers could not do what steam engineers could, they had better learn how to. He then proposed a vote of thanks to Mr. Cowan and Mr. Still, which was carried unanimously.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

April 14, 8 p.m.—At the Institution, Great George-street, Westminster. Ordinary meeting. "The Thirlmere Works for the Water Supply of Manchester," by G. H. Hill (member). "The Vyrnwy Works for the Water Supply of Liverpool," by G. F. Deacon (member). At this meeting the monthly ballot for members will be taken.

April 15, 3.30 p.m.—At Great George-street. Special general meeting to consider alterations in the by-laws.

April 17, 8 p.m.—Students' meeting. "Recent Developments in Lighthouse Engineering," by N. G. Gedye (student).

Institution of Electrical Engineers.

April 16, 8 p.m.—At the Institution of Civil Engineers, 25, Great George-street, Westminster. Ordinary general meeting. Discussion on Dane Sinclair's paper on "Telephone Exchanges and their Working."

Northern Society of Electrical Engineers.

April 13, 8 p.m.—At the Palatine Hotel, Manchester. Ordinary general meeting. Lecture and demonstration of the new photography, with lantern views, by C. M. Dorman (member). After the lecture the members of the society will visit the Manchester Corporation battery station, on the invitation of Mr. C. H. Wordingham.

Institution of Junior Engineers.

April 17, 8 p.m.—At the Westminster Palace Hotel. Paper on "Dredgers," by W. J. Hunter.

Society of Arts.

April 13, 8 p.m.—At John-street, Adelphi, W.C. Cantor lecture on "Precious Stones," by Prof. H. Miers.

April 15, 8 p.m.—"Early English Organ Writers," by B. Horner.

Royal Meteorological Society.

April 15, 7.30 p.m.—At the Institution of Civil Engineers, Great George-street. "Mean Amount of Cloud Each Day, from 1841 to 1890," by William Ellis. F.R.S.; "Atmospheric Dust Observations," by E. D. Fridlander, B.Sc.; and "Analysis of the Greenwich Rainfall Records, with reference to the Declination of the Sun and Moon," by Major H. E. Rawson, R.E., F.R.Met.Soc.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

BOILERS.

The question as to what type of boiler is most suitable for generating steam for electric light stations is one that cannot be answered without a careful study of the subject. In this department, as in many others connected with the electric supply in towns, certain early stations are apt to be copied without due consideration of the altered climatical conditions. An article on the subject recently printed in the *Engineer*, and given elsewhere in our columns, assumes that this has been done. The writer compares the boiler practice in mill work with that in electric light stations, and concludes that Lancashire boilers should be more widely used. We endorse this opinion, but protest that the so-called craze for water-tube boilers was not the result of haphazard, but rather the outcome of careful study. The condition of steam generation and the demand for power in mill work cannot be compared to that in electric light stations. In the first case the load is fairly constant throughout the working day, the fluctuations rarely exceeding 25 per cent. of the average output. On the other hand, the demand for steam in an ordinary electric light station varies largely at different times in the day, and at light load the output is often under one-twenty-fifth of the full load. Now, when these changes can be approximately foreseen, the Lancashire boiler will meet the requirements of the town; and the fact that this type of boiler has been solely used in such stations as those at Bristol, Newcastle-on-Tyne, Blackpool, Walsall, Stafford, Manchester, and many other places, shows that the water-tube boiler has not been blindly adopted. The writer of the article will be surprised to hear that of the provincial stations an ample majority are equipped with the Lancashire type of boiler. In the electric light stations in London the water-tube boiler has carried all before it, and we would uphold this practice. The chief reason for this result has doubtless been its quick steaming properties. The electric light supply must necessarily be continuous, and the sudden demand when a fog arises in London could not be met with Lancashire boilers without considerable loss due to boilers standing under steam. There is no doubt but that the large water spaces in these boilers give an advantage when dealing with a sudden and temporary increase of load, but the same storage effect acts prejudicially when boilers have to be brought quickly up to the working pressure. Again, while for large and fairly even demands the Lancashire type has the advantage in the annual expenditure on repairs, it must not be forgotten that ground space in the Metropolis is extremely valuable, and that the water-tube boiler scores heavily in this respect, and also in ease of erection when the ground space and approaches are cramped. The efficiency of a boiler can, as is well known, be largely increased by a decrease in the rate of steam generation, which fact renders the comparison of different types of boilers a difficult matter. Thus, working a large number of boilers lightly would appear to be more advantageous than keeping a few boilers working at their full load.

Digitized by Google

The losses due to radiation from the boilers and their settings would, however, neutralise the apparent gain to a great extent. Although efficiency thus needs care in comparison, the item for annual repairs is always ascertainable, and from it useful lessons may be drawn in support of the country practice in boiler work for electricity stations. The gist of the whole matter lies in the load diagrams, which in London are very erratic. The promptitude with which these unexpected irregularities are met by the staffs of our London supply stations is worthy of every commendation, but the strain occasioned by the sudden demand could not be met by the ordinary mill practice.

Justice needs that both be heard."

THE SNOWDON RACK RAILWAY.

SIR,—Last Monday's lamentable accident on the Snowdon Railroad will, perhaps, invest with a melancholy interest the article you were good enough to publish under my name a week ago, though I fear the developments in rack lines therein anticipated will now be delayed for some time as a consequence of the runaway on Snowdon.

One can hardly attempt at present to suggest what may have been the real cause of the accident, especially in view of the Board of Trade enquiry, at which full particulars will doubtless be forthcoming. The so-called "official" account is certainly not clear or consistent: it speaks of the rack as being damaged, although both the carriages of the first train and the second train as a whole were pulled up by its means. Moreover, it is extremely difficult to believe that the first engine mounted the rack whilst still on the line and under control. The engine must have been travelling at too high a speed, probably beyond control, and then mounted the ordinary rails at a curve, thereby getting out of gear with the rack. Such an occurrence had not happened before, and is hardly likely to happen again.

I must not theorise, however; my chief object in writing is to point out that if the motive gear had been electrical, and therefore placed in the usual way under the passenger car framework or on the trucks, there would have been much less danger, even in case of a momentary runaway. For emergency stops on a heavy locomotive and train under such conditions, it is usual to employ an arrangement which puts on the rack brake automatically when a certain maximum speed is reached. I do not know whether this device came into play on Monday; it could hardly find an opportunity to do so if the locomotive left the rails before reaching the maximum speed permissible. That the cars should have attained a high speed and yet kept on the line shows, I think, that their construction was such as to allow them to run safely where the engine could not.

If any moral may safely be drawn—pending more details of what actually took place—it would seem to be the following: with railways of this character, motorcars as employed on all electric lines have great constructional advantages for ease of braking and controlling generally in regard to the somewhat remote possibility of excessive speed, as well as in ordinary working.—Yours, etc.,

London, April 8, 1896. FRANK B. LEA.

THE INSTITUTION BALANCE-SHEET.

SIR,—I have read your article of the 3rd inst. on the "Institution Balance-Sheet" with mingled astonishment and pain.

With the misstatements of fact I will not deal, as they will in due time be corrected by a perusal of the *Journal*, but there is a suggestion put to your readers—evidently a reflection of your own opinion—which I cannot allow to pass without protest. The said suggestion appears in this form: "We should much like to know if the real juice was not the wish to pass a vote of censure on the honorary treasurer?"

In the first place, there was no wish to pass a vote of censure on anyone, as was evidenced by my repeated offer to adjourn the debate or to withdraw the amendment.

In the second place, I am not aware that the honorary treasurer was in any way responsible for the form of the balance sheet or for its accuracy.

In the third place, the honorary treasurer is a gentleman with whom I am, and have been for several years past, on terms of friendly intercourse.

Of course, there have been differences of opinion; it was impossible for it to have been otherwise, considering the wide range of subjects which has come under review, but in this latter half of the nineteenth century it would be childish to make such differences of opinion a ground for the abrogation of personal esteem or for the total disregard on my part of those sentiments of admiration and gratitude towards the honorary treasurer of the Institution which I have long felt, and which I endeavoured feebly (and it now appears ineffectually) to express to the members present in the course of my address on the balance-sheet.

It may interest you and your readers to learn that, so far from the time having been wasted which was accorded to the discussion of fundamental matters at the annual meeting on December 12, it has resulted in the drafting of numerous amendments to the articles of association—which amendments, with the concurrence of my friends, I took the liberty of bringing under the notice of the President in preference to calling a general meeting for their consideration. The result is that the said amendments have been submitted to a committee of the Council which included the honorary treasurer, and their report which is now before the Council is, I have been informed, generally in accord with the spirit of the amendments submitted.

I am sure, Sir, that you are actuated by motives which have no other object than the support of the Institution so far as it endeavours to fulfil the duties for which it was created, and I respectfully submit to you the suggestion that there may be other members or associates who are or may be actuated by similar or at least not less honourable motives.—Yours, etc.,

JOHN S. RAWORTH.

[We cannot say that Mr. Raworth's letter alters our impression of the true state of affairs. He admits, in the first place, that the amendment was a vote of censure, and that he called for a division because the waste of time was objected to by the President. Secondly, we can hardly imagine what Mr. Raworth's ideas of the duties of the honorary treasurer are. The gentleman in question took a lively interest in the remarks of Mr. Raworth, and showed his connection with the balance sheet by one or two interruptions. Again, if the Council so readily acted on the suggestions brought forward on December 12 without a motion having been put, Mr. Raworth might at least have trusted the present small matter in their hands. We repeat that the whole of the "juice" spoken or printed on the subject of the amendment could have been done ample justice to in the course of a five-minutes' speech.—ED. *E. E.*]

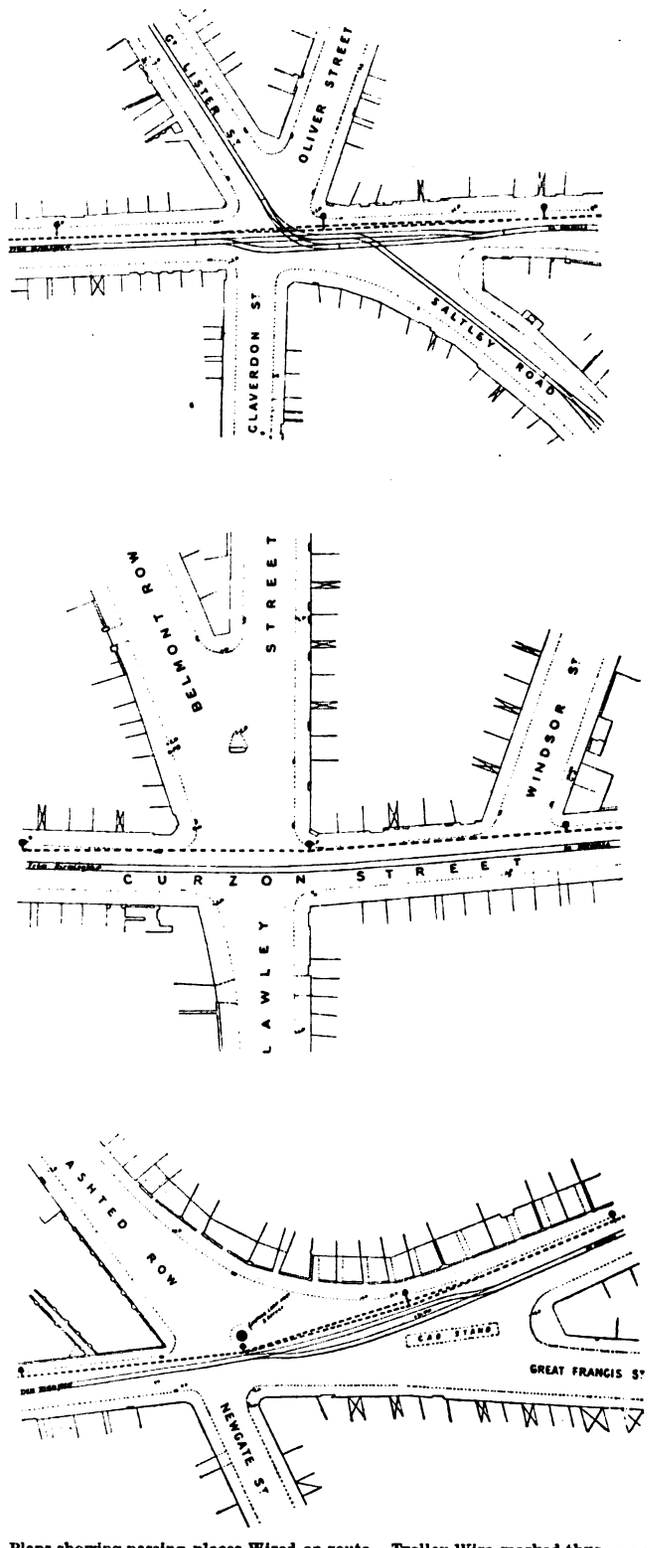
BIRMINGHAM ELECTRIC TRAMWAYS.

In our issue of August 15, 1890, will be found a description of the Bristol-road electric tramway, which forms a portion of the Birmingham Tramways Company's system—in fact, that portion which is worked electrically. The engineers, as will be seen from our description, were Messrs. E. Pritchard, M.I.C.E., and Joseph Kincaid, M.I.C.E, who designed the permanent way outside the city boundary and also the depôt and the electric installation. The recent meeting of municipal engineers at King's Heath had as part of its programme a visit to Bournbrook, the depôt for this Bristol-road section of the tramway. This visit gave us another opportunity of inspecting a line

Digitized by Google

which has been worked on the accumulator system since its start to the present day. So far as the works themselves are concerned there is very little change, and so far as the system is concerned there is also very little change except that various types of accumulators have been tried, and it has been found that, no matter what type of accumulator is used, the expenses of the line are so great that profits vanish ; in fact, if an examination be made of the balance-sheets of the Birmingham Central Tramways Company during the past few years, it will be seen that while the steam department, the horse department, and cable department all had a balance to revenue account, the electric department, with the exception of one year, has had a balance on the wrong side, and even in the case where the balance seems on the right side, that probably arises from the way in which the accounts are made, in that the expenses do not include the Corporation charges. However, we have dealt with these balance-sheets periodically as they were issued, and it is needless for us to consider them again. We may, however, venture to give a few details regarding the line so far as we can obtain information of the working by means of the accumulators at the present time. The accumulators now in use are of the Chloride Electrical Storage Syndicate's manufacture, which have been installed for about 18 months. The syndicate's contract with the tramway company is based on the car mileage run, with a stipulation to the effect that 17 batteries shall be maintained in an efficient state. We may add here that the length of line worked is 3 miles 153 yards double track, and the number of cars running over it at any one time varies with the time of day, sometimes the number being five, and at others nine, while three are always kept in reserve. Various experiments with different types of batteries have shown that each line wants to be treated on its own merits, having regard to the weight of the cars, etc., and in order to calculate the best efficiency and the longest life for each kind of car the number of cells contained in the batteries has been varied. Batteries weighing from $1\frac{3}{4}$ to $2\frac{3}{4}$ tons, on cars weighing—without batteries, but with passengers—about 10 tons, have been tried. We understand that the 17 batteries of 72 cells each which are now at the depôt are of the R Chloride type, and each battery will run for about six hours when new. The battery is not considered inefficient until it refuses to do less than two hours' run without recharging. So far as the life of the plates is concerned, this type only having been installed for about 18 months, and having regard to the different patterns which have been experimented with, sufficient data is not forthcoming to justify any definite statement. As regards running with accumulators, the Chloride Company hold that it is the proper course to adopt where there is not a sufficiently frequent service to justify the instalment of an overhead-wire system.

Previous to this, Epstein and also E.P.S. accumulators were given a trial. Mr. Epstein has more than once given full details as to the working of the accumulators which bear his name, the gist of which we may again venture to reproduce. It was about the beginning of 1892 when they were first installed, and as the plates of this type are composed of a single lead casting in the form of ridges, supported by a web, and, moreover, contain no straps or built-up parts, they are claimed to be particularly suitable for withstanding the shaking and rough usage incidental to tramway work. The history of the batteries in working at Birmingham was carefully recorded by the Epstein Company, and, as a result, it was found that 12 sets of 92 cells made an average car mileage of considerably over 15,000 miles without requiring renewal. The cells were supplied under a maintenance contract calculated at $1\frac{1}{2}$d. per car mile. With a run of 15,000 miles this gives something more than £93, and as the number of cells per car was subsequently reduced from 92 to 72 it amounts to just under £1. 6s. per cell. Now, as the cost of such a cell when the trade discount is deducted would be about £2. 8s. for the two plates, the ebonite casing, and all accessories—while so far as renewals are concerned there is practically only one plate to consider—it will be seen that this arrangement was one that should have proved profitable to the contractor, and the rate mentioned of $1\frac{1}{2}$d. per car mile run might well be reduced. Using the Epstein cells, the cars were run with great regularity under circumstances of great difficulty owing to the severe winter of 1892-93 Indeed, so far as concerns keeping their times the cars showed a decided superiority to those that were running on other systems in Birmingham at the same period.



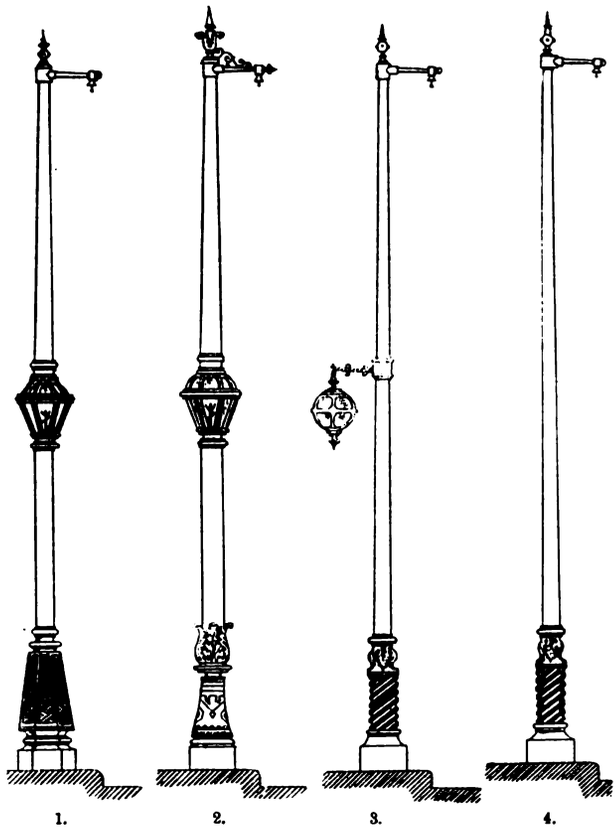
Plans showing passing places Wired on route. Trolley Wire marked thus - - - -
• L P signifies existing Lamp-posts.

For reasons, however, which doubtless seemed good to them, the Board of the tramway company largely transferred their orders to the Electrical Power Storage Company, but gave their accumulators up after a comparatively short time, and tried the Chloride Syndicate. The latter company, as we have mentioned above, instead of selling the accumulators right out, entered into an agreement on the basis of the car mileage worked, and the cars are still being run on those terms. With the Epstein cells, we may add, a total car mileage of 188,000 was run at a cost of

Digitized by Google

about 1s. 3d. to 1s. 2d. per car mile, a rate which Mr. Epstein thinks, under present conditions, might be somewhat reduced. As regards the E.P.S. cells there is no information available. The present contractors consider the conditions of running on the Bristol-road line are very much against the success of the accumulators from a financial point of view, the cars being very heavy and inefficient. With better cars and motors, it is claimed the work could be done more economically. Then, again, the Corporation, for the three odd miles of double track, exact a rental of £2,000, whilst the cable line has to pay about £1,000 for double the mileage. The actual cost for batteries works out at less than 10 per cent. of the total cost per mile run.

The Birmingham Central Tramways Company, Limited, practically have the monopoly of the tramway and omnibus services through the city and suburbs of Birmingham. The former services extend over some 43 miles of line, and although horse and steam traction at present predominate over this extensive system, there are also two lines which have been satisfactorily worked for some years past by means of cables—besides the line



Submitted Designs for Poles.

worked electrically which we have spoken of at some length above. The time, however, seems within reasonable distance when, besides these several modes of traction, the overhead conductor system of electric propulsion will also be represented at Birmingham. Some time ago the tramways company decided to equip a portion of their lines for working on the overhead system, and in order to more readily obtain the consent of the City Council—which now, by-the-bye, has been obtained—to the proposed scheme, Mr. Alfred Dickinson, A.M.I.C.E., engineer to the company, collected a mass of information in the shape of letters *re* the South Staffordshire electric tramways. The object of the information so collected was to demonstrate the fact that although strenuous opposition was offered to the adoption of an overhead conductor system of electric traction on the South Staffordshire lines, objection to the service no longer exists to any great extent. A glance through the letters in answer to Mr. Dickinson's enquiries from some of the principal residents in the Walsall and Wednesbury districts shows us that the general census of opinion obtained was entirely in favour of the overhead system; their purpose was therefore well served. These letters, together with a few illustrations and drawings—some of which we reproduce herewith—were placed before the Public Works Committee, the better to guide them in making their report to the Council. The line proposed to be equipped is that running between Birmingham and Nechells, a distance of 2 miles 1 furlong 117 yards. It is at present worked by horses, though the gradients are by no means inconsiderable, the fall at the Birmingham end being as much as 1 in 16. The permanent way consists of a single track of rails, with cross-overs or passing places at intervals, and is in such excellent condition that it is not proposed to relay the metals, but simply to bond them, that they may be utilised as a return. The accompanying drawings show at a glance the proposed method of wiring the principal passing places; it will be seen that the supports necessary for the trolley wire are very few. In the proposed method of running the trolley wire, etc., the engineers, Messrs. Alfred Dickinson and Co., have aimed at an improvement on the South Staffordshire system. The trolley-wire poles, carrying gas-lamps, will be placed in the positions occupied by existing lamp-posts, and will therefore serve a double purpose. We reproduce several submitted designs of these proposed combination poles, but the one most likely to be finally approved is, we understand, an amendment on the No. 3 design, which, instead of the one lamp as depicted, will carry a couple, one branching out on either side. Moreover, the lamps, instead of being globular in form, will be of similar design to those at present in use. It is intended to give the trolley arms great radial play so as to reduce the length of the brackets supporting the trolley wire to a minimum. The actual distance between the trolley wire and pole will be reduced by this means to an insignificant 18in., so that the brackets will hardly be noticeable. The trolley wire itself will be of the same gauge as that on the South Staffordshire line—namely, 312·5 mils, and a feeder will be connected to it at a point about 1¾ miles distant from the depôt. It is proposed to use the Etna type of insulator throughout. Lines worked by steam cars intersect the Nechells route, so that in case of necessity either horse or steam cars could be substituted for the electric ones, the gauges being similar. With regard to the necessary plant for working the line, it is proposed to instal at the company's Nechells depôt—where ample accommodation exists without erecting new buildings—a couple of 100-i.h.p. under-type engines, driving by means of ropes a similar number of 100-kilowatt dynamos, working at 500 volts pressure. Either of the units composing this duplicate set would be capable of comfortably working the line, so that one set of machinery would always be held in reserve. An attempt is to be made to convert existing horse cars for service on the line, and to this end 10 cars suitable for conversion are to be taken in hand and equipped with motors, etc. Offers have already been obtained by the tramways company from firms willing to instal the necessary plant, etc., and to work the line for six months, after which period the tramways company to have the option of taking over the plant at a price previously agreed upon. The whole matter is likely to be settled and the work commenced very shortly. The scheme, however, must be regarded in the light of an experiment, and as such its progress will be watched with interest, expecially in that successful issue would probably lead to the conversion of many more miles of the Birmingham tramways to that of the electrical system. We therefore heartily wish success to this—Mr. Alfred Dickinson's—proposed conversion scheme.

CAN AN ELECTRIC CIRCUIT BE OPENED WITHOUT AN ARC? *

BY A. J. WURTS.

The opening of an electric circuit is ordinarily accompanied by an arc which causes more or less damage to the switch terminals. The extent of this damage is in general dependent on the amount of current flowing and on certain characteristics of the circuit and generating apparatus.

Up to very recent times electric circuits have been handled

* From the *Electrical Engineer* (New York).

Digitized by Google

with switches constructed without special reference to arcing, the deteriorating action of the arc not being sufficient to warrant special constructions. With modern lighting and power-transmission circuits, however, the problem has assumed quite different proportions, so that not only are ordinary switches rapidly destroyed in the handling of these circuits, but an element of danger is also introduced To-day electric arcs 6ft. long are not uncommon.

While experimenting some time ago with static discharges I had occasion to pass a small discharge across a $\frac{1}{32}$in. gap between electrodes which were placed in a heavy glass tube filled with oil and securely corked at either end. Much to my surprise, at the time when the discharge occurred, the glass tube was broken into small fragments; it did not burst as by an explosion, the tube simply fell to pieces. The experiment was repeated a number of times with the same result. I subsequently analysed the experiment as follows:

An electric arc requires space. The glass tube was filled with an incompressible fluid possessing considerable inertia. An arc which might form within this fluid would be obliged to displace the fluid, which, in turn, being incompressible, would force out the walls of the containing vessel; the latter being brittle were broken into fragments. The force which broke the vessel was the E.M.F. which forced the arc across the spark gap. The elastic corks could not play the part of cushions and thereby save the tube because the displacement of the oil was sudden—the oil was not pushed away by the arc, but knocked away, as with a hammer—and because the inertia of the oil between the arc and the corks was greater than that between the arc and the walls of the tube—in other words, the force became active in the direction of least inertia. Reasoning further, it seemed that if the vessel had been relatively stronger than the E.M.F. the arc could not have formed—in other words, it seemed as though the elements were at hand for the construction of a switch capable of opening an electric circuit without an arc.

Following out these ideas, I constructed an ordinary electric switch of about 100 amperes capacity, which was suitably located in a sealed cast-iron vessel filled with oil. On placing this switch in a 500 volt direct-current circuit, I opened and closed the switch some eight or ten times on 30 amperes, and upon removing the stopper from the cast-iron vessel was surprised to see the oil spurt. On examining the oil I found it had been considerably carbonised. The accumulation of pressure and the carbonisation of the oil indicated the formation of an arc at the switch terminals, which for a time puzzled me considerably, as the formation of an arc had not entered into my calculations. On repeating the experiment I neglected to replace the stopper, with the result that when the switch was opened a column of oil was forced into the air about 6ft. high. Testing again with the vessel closed I detected a slight gurgling sound when the switch was opened.

Being still puzzled, I determined to see what was going on within the vessel and had a heavy glass front constructed. Repeating the experiments, I noticed that on opening the circuit an arc was formed about the size of a pea. The same arc in air would have been about 3in. long. After about a dozen breaks, however, the glass front was shattered, as though struck by a hammer. On further considering these results, it seemed to me that either the vessel had not been entirely filled with the oil or that the vessel was sufficiently elastic to allow the formation of the small arc noticed. It is not unlikely that both of these conjectures were true. However, the arc which actually formed was so insignificant that I felt encouraged and proceeded with my experiments, hoping to eventually produce results of practical value.

My first step was to overcome the pressure which accumulated, due to the formation of gases by the arc in the oil. I placed in connection with the containing vessel a small reservoir, having a direct pinhole communication with the main vessel, also a valve connection allowing oil to pass from the reservoir into the main vessel by gravity. The pinhole communication was placed in a dome directly over the switch terminals, so that the gases which formed would rise to the top of the dome and pass out into the reservoir, which latter was only partially filled with oil. The pressure being thereby released in the switch chamber, sufficient oil would flow through the valve communication from the reservoir to occupy the space which had been previously occupied by the gas. This plan proving satisfactory, I proceeded to determine the life of the switch as compared with a similar switch used for the same purpose in the open air. After making about 3,000 breaks I found that the oil had carbonised to such an extent that with the switch open there was a current leakage of several amperes. Various oils were subsequently tried, some of which proved better than others. Of these paraffin oil gave the best results.

I next tried glycerine and with it made 40,000 breaks. At the end of this test the switch terminals were found to be slightly scarred, the glycerine was black from carbonisation, but the current leakage was only a small fraction of an ampere on open circuit.

Having arrived at this point, I began to experience difficulty with the containing vessel, which now leaked badly in spite of the best fittings I could procure. To overcome this difficulty, I determined to increase the density of the liquid. It seemed to me that not only would a more dense liquid be less easily forced through the joints, which necessarily enter into the construction of the apparatus, but that it would also more effectually resist the formation of the arc. Satisfactory tests were made with a mixture of precipitated silica and glycerine.

Aside from the above results, the question "Can an electric circuit be opened without an arc?" is exceedingly interesting from theoretical as well as practical standpoints. In connection with electrical engineering problems of the day, it is one of no small importance.

TELEPHONE EXCHANGES AND THEIR WORKING.*

BY DANE SINCLAIR, MEMBER.

(Concluded from page 383.)

I have before now been accused of something like inconsistency in advising in favour of this system in some places and against it in others. In deciding upon any particular case the local circumstances have to be take into consideration, and after a careful study of the subject the decision I have arrived at is that, given a town where all, or nearly all, the subscribers' lines terminate in one exchange, there is no doubt that the call wire gives the most perfect service. For this reason we have introduced the call wire into Glasgow and nearly all the towns in Scotland. We are also introducing it into Manchester. It would, however, be absolutely unworkable in London. The full explanation of this would take more time than can be given to it in a paper of this kind; but, broadly, it may be said that in a great city like London, where there are a number of exchanges, and consequently the subscribers' lines terminate at a number of different centres, the call wire becomes unsuitable. Let us take an instance. Suppose a subscriber on our King's Cross exchange, whose office has been fitted with the call wire, wishes to communicate with a subscriber on Lime-street exchange, in the City, he presses his call-wire key and gives the listening operator the number of the subscriber he requires. The operator has then to do one of two things: she has either to cut herself off from the local call wire, in which case the main feature of the call wire—viz, continuous listening—is sacrificed, or to connect her telephone, as well as the call wire with its 50 subscribers, on to a call wire to the City. Other operators in the same exchange may have been asked by their subscribers for subscribers in the City, and may also have connected their call wires to the same City wire. In the event of a connection having to be made through two or three exchanges this trouble would be increased, and it would often be found that operating would be rendered impossible, owing to the large number of subscribers connected together all clamouring for their instructions to be taken first. The effect would be somewhat similar to that of a crowd of people attempting to rush out of a public building, on an alarm of fire, through a doorway too small to accommodate them; they simply get jammed in the doorway, with the unhappy result that they perish in the attempt. In the same way, the subscriber at King's Cross might stand at his instrument and perish before he succeeded in getting through to the subscriber in the City. With this explanation it will, I am sure, be apparent to anyone who thoroughly studies the matter how it is that the call wire may be successful at one centre where all, or nearly all, the subscribers' lines are grouped in one exchange, and be a complete

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

failure if introduced into an exchange system like that of London.

All things being considered, we find that the call wire gives more satisfaction than the indicator system, and it is perhaps to be regretted that it cannot be introduced under all circumstances. We had the indicator system with multiple boards at work for many years at Glasgow, and we changed to the call-wire system. Nine months after the introduction of the new system the subscribers were asked whether they preferred the call-wire or the indicator system previously in use, with the result that 95 per cent. of the subscribers were in favour of the new system; and it was this result that decided the question in favour of its introduction into Manchester. The call wire has been in use almost since the introduction of telephone exchanges, and here again I find that our friends on the other side of the Atlantic at a very early date saw the advantages to be derived from it, with both the make-and-break and the branching system. It is the latter system which is being introduced at Manchester. It so happens that at Manchester 90 per cent. of our subscribers have their lines terminating in the central exchange, and, consequently, it is a highly suitable place for the introduction of the call-wire system. We are now installing it there in connection with a new exchange which is being fitted with flat boards. The Manchester board is illustrated in the drawing Fig. 7. It will be seen that it differs somewhat in detail from that with self-restoring indicators which has been already described. The board will accommodate 7,200 subscribers' lines, and is now being fitted complete for 4,800, with the necessary trunk and junction wires in addition. The design of the framework has been so modified as to allow the operators to get nearer to the line jacks, which gives greater facilities for operating.

I may now refer to a few load curves (Figs. 8 and 9) I have prepared showing the number of calls passing through our busiest exchanges. At the top of these we find Liverpool, where the average number of calls per subscriber per day amounts to 18·6. The pressure of the work will, however, be better understood by noticing that at certain hours of the day the number of calls is very high.

An important part of an exchange system in a place like London is the proper arrangement and working of the junction wires between the different exchanges. I have found that the best way to arrange these is to have, in addition to the direct wires, a central junction-wire exchange, between which and every other exchange two or more wires are provided. It will be readily understood that in a system like that of London, where there are 37 exchanges, it would be impracticable to run from each new exchange opened in the suburbs direct wires to all the others. Therefore the central junction exchange becomes a necessity. It is obvious, however, that such a central exchange must introduce extra operating, and consequent delay, into the service, and, therefore, where we have as many as 60 or 70 messages per day between any two exchanges, we provide two direct junction wires. Beyond this, an additional junction wire is provided for each 40 messages per day. Taking the average duration of each call as three minutes, it will easily be seen that, to meet the maximum pressure at the busiest time of the day, so many junction wires have to be provided that the average time each is in use amounts to only two hours out of the 24.

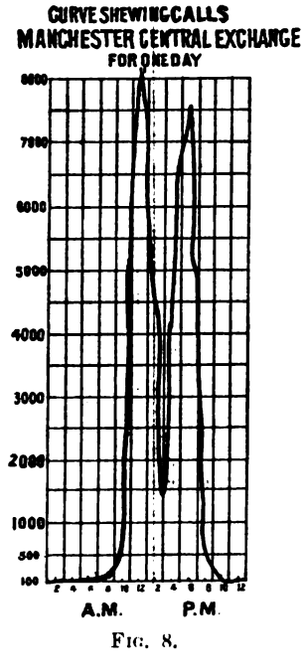

Fig. 8.

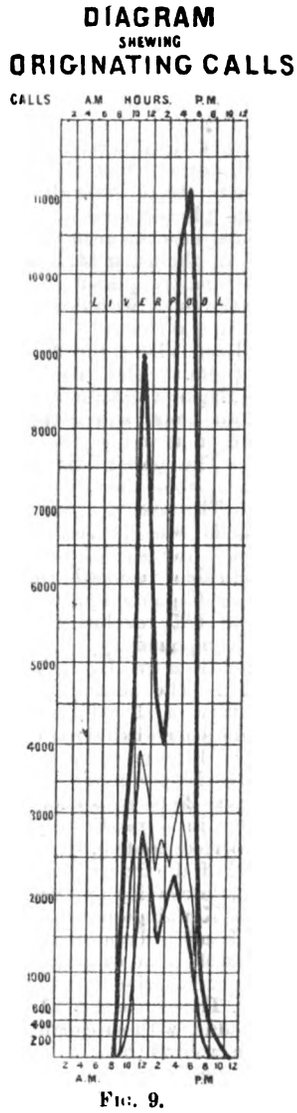

Fig. 9.

ELECTRIC TRACTION FOR TRAMWAYS.

The following is a copy of the report of the deputation appointed by the Belfast Corporation to visit various cities and towns where tramway traction by electricity is in practice, and report for the information of the Council:

The deputation inspected the various systems of mechanical traction as applied to tramways in the cities mentioned below, and they have much pleasure in recording the great courtesy and hospitality shown to them everywhere, and the marked willingness to impart information by the authorities and officials and by the officers of the different companies.

Dublin, Kingstown, and Bray.—This line is not yet opened for traffic, but some members of the deputation, also Sir Daniel Dixon and Sir William M'Cammond, were afforded an opportunity of inspecting it. A considerable portion of the line was formerly an ordinary horse one, but has been laid and arranged for overhead electrical traction. The experimental trip was very satisfactory. In this case the electricity is sent out at a

Digitized by Google

high voltage and afterwards reduced by transformers at sub-stations.

Bristol.—The Bristol, St. George, and Kingswood tramways were opened in October last. The line commences at the western end of Old Market-street, where it joins two lines for horse cars, and extends for about four miles to Kingswood, the gradients being fairly easy for the most part, but for some portions have an incline of 1 in 15. The gauge of the line is the English railway gauge of 4ft. 8½in., same as the Belfast street tramways. In most of the route there is a double tramway track. The rails are of the ordinary flange type, weighing about 76lb. per yard. Two overhead copper trolley wires, 0 32in. in diameter, extend the whole length of the line and about 20ft. above street level. The wires supply the current to cars running in opposite directions. An armoured feeder is laid along the whole length of the line under the adjacent footway, immediately behind the kerbstone. The return current to the dynamo is obtained from the trolley wire through the car and along the rails, which are specially coupled together with copper attachments. In addition to the feeder, there is a three-strand insulated and armoured conductor laid the whole length of the line for telephonic and testing purposes. The trolley wires are supported at every 40 yards by ornamental cast-iron columns, with transverse arms, the trolley wires being suspended at the extremities of the arm. The public enter and leave the cars (as is generally the case on most lines) at special stopping places, marked upon the columns. The columns are sunk into the ground about 6ft., and surrounded with concrete. In the wider streets these columns, protected by cast-iron fenders, are placed in the centre way (5ft. 6in. in width) between the lines, with double projecting arms. Where the streets are not sufficiently wide for this arrangement, the columns are placed along the footways in the position of ordinary lamp-posts. The maximum speed on this and other lines in England sanctioned by the Board of Trade is eight miles an hour, and there is no difficulty in maintaining that rate, nor would there be of greatly exceeding it, if desired. The power station in Beaconsfield-road is about equidistant from the extreme ends of the electrical tramway lines. The greater part of the ground on which the station stands was previously occupied by the company's stables and car sheds, the buildings of which were, so far as practicable, utilised therefor. There are three dynamos, each yielding an output of 200 amperes, at 500 volts, when working at 650 revolutions per minute. The driving engines are of compound type, 135 h.p. at 380 revolutions. Steam is supplied from two Lancashire boilers, with a working pressure of 140lb. The accumulators at the central station consist of a battery of 55 cells, each cell having a capacity of 546 ampere-hours when discharged in six hours. The cars are lighted by electrical incandescent lamps from the main circuit. Each car is fitted with two motors, controllers, and other appliances, and will seat 20 persons inside and 24 on the roof. The cars were driven in a satisfactory manner, and under what appeared to be perfect control, the electric controller on the car regulating at will of the driver the speed or stoppage of the cars in ascending and descending gradients.

London.—The Kennington and Streatham Cable Tramway (worked by the London Tramways Company) commences near Kennington Church, and extends in a southerly direction to Streatham, the system being about 3½ miles in length, on double lines throughout. The centre slot is 1in. wide, the cable being laid in a concrete conduit with supporting trolleys about every 60ft. At each of these trolleys there is a small opening with covered plates to give access for repairs and oiling. The rope is of steel wire, working at each terminus over a wheel of about 10ft. diameter. The power station is situated about 2½ miles south of Kennington Church, and is driven by two powerful compound engines, the steam being supplied by a series of Babcock and Wilcox boilers. Coke is the fuel used. An elaborate system of underground subways is required to conduct the driving ropes to their working position under the tramway line. The cars are of the usual type, and are run not only over the cable system, but over other lines of the London Tramway Company worked by horse traction. The horses bring the cars to the Kennington Church terminus, whence they are drawn by separate driving or "dummy" cars, of which about 40 are in use. The grip on the cable seems to be made gently at first, to avoid shock, necessarily causing a slipping and friction on the cable. The maximum speed allowed by the Board of Trade is eight miles an hour, and the average running is about six miles an hour.

Havre.—The electrical tramways in Havre are about eight miles in length, running through the central as well as the suburban portions of the town. The lines are for the most part double, although in some of the narrower streets, and in the suburban line to St. Addresse, a single line is adopted. In the wider streets there are placed central iron columns with projecting arms in a similar manner to those at Bristol. For the greater portion of the lines iron columns (without arms) are placed opposite each other in the footways with connecting cross wires, from which are suspended the overhead trolley wire, and in a few places where it is inconvenient to place columns the cross wires are stretched from building to building and attached thereto by ornamental rosettes. The deputation were informed that leave to make these attachments to buildings was easily obtained from the owners and occupiers of property. The poles for supporting the overhead trolley wire are placed from 131ft. to 164ft. apart. The main feeder is laid at the side of the line in earthenware pipes. Two wires are placed over the trolley wire in some portions of the line, which serve not only for telephonic communication, but also to prevent the contact of any overhead telephone wires accidentally falling upon the trolley wire. The general arrangements as to motors, controllers, and trolley are similar to those at Bristol. There are about 40 motorcars at present in use. The gradients through a considerable portion of the town are easy, but in the higher districts they reach an inclination of about 1 in 17, and do not cause any inconvenience in traction. The power for working the line is supplied by a company distinct from the tramway company, and which also supplies the lighting for the city and harbour. The greatest distance of any portion of the tramway lines from the power station is about 2½ miles. The maximum given from the dynamo is 500 volts. They have no accumulators in the power station.

Paris.—There are three different methods of mechanical traction for tramways here—(1) cars worked by compressed air; (2) the Serpollet steam trams; (3) electric cars run by accumulators. Each of these systems appear to be more or less cumbrous and unsightly, especially in the case of the compressed-air car, which weighs no less than 22 tons, exclusive of the trailer car. The compressed air and accumulator cars are charged at each terminus, the former being worked at an initial pressure of 50 atmospheres, with reducing valves to diminish the pressure at will.

Brussels.—The Brussels tramways were installed by the Union Electrical Company of Berlin. The lines supplied electrically are those from north to south by the Circular Boulevard and the branch lines from Brussels to Uccle. The cars are driven from two trolley wires, divided into sections of about 1,640ft., each section being connected at its extremities to the feeder by cables rising inside the columns. The cable is placed in the soil without any other protection than a layer of bricks laid dry in order to denote its presence during future works along the line. These cables are supplied with interrupters, which permit any one section to become out of circuit in case of necessity. All along the boulevards the trolley wires are suspended to ornamental brackets, supported by tubular columns. In the streets the wire is carried by steel cross wires fixed to the façade of adjacent buildings. In order to facilitate the return of the current, the rails are bound at each joint by two lengths of copper wire, fixed to the rail by means of rivets in mild steel. Strips of creosoted wood are placed over the trolley wires to protect them from the fall of overhead telephone wires. Each car is lighted by five incandescent lamps of 100 volts, obtained immediately between the trolley and the rails. The length of the boulevard line is about three miles (double width), and of the line to Uccle two and a half miles (mostly single line). The minimum radius of the curves is about 82ft., with a gradient of 1 in 15. The rolling-stock embraces 26 covered cars, each containing seats for 16 persons and room for 20 persons standing at the ends. Each car carries two motors. The weight of the car is 6·3 tons, and nearly 9 tons when full. The rate of speed averages 7½ miles an hour. The machinery in the power station comprises five compound non-condensing engines and three Babcock and Wilcox boilers. The five dynamos are each of 100 kilowatts (500 volts, 200 amperes) of normal duty. The switchboard contains automatic circuit-breakers to break the circuit when the load on the dynamos exceeds the maximum. There are no accumulators at the power station. The service of the cars occurs at very close intervals. Another electrical tramway from the city to the Petite Espinette is vested in another company. The gauge of this tramway is 3ft. 2in. The rails weigh 46·3lb. per metre, with plate riveted on rail to form the groove, bringing the weight up to 68·3lb. per metre. The service on this line is every 10 minutes in summer and 15 in winter. There is one curve on this line of 115ft. radius on a sharp incline, but there is no difficulty in traversing it. The power station is practically on the same lines as that of the last-mentioned line. The most distant part of this tramway is about 8½ miles from the power station. In several portions of the line the wires are carried by means of transverse wires, attached to the buildings by means of ornamental rosettes, but in the more distant portions of the line, which traverse what may be termed a country road, these cross wires are at present attached to unsightly wooden poles at the sides of the road, but are now being replaced by light ornamental iron ones.

Hanover.—The system adopted here is that of the overhead wires, except in the more central portions of the city, where the cars cease taking power from the trolley line, and work from accumulators placed under the seats. These accumulators are charged from the trolley wire whilst the cars are running with that method of contact. Although there are only eight such

Digitized by Google

cars running now, there will be 60 in three months, as the present horse tramways are to be supplanted by them. The accumulators give an extra load to the cars of about 1¼ tons. In place of the ordinary trolley attachment the Siemens rectangle trolley frame is used, for which is claimed, amongst other advantages, the reduction of the necessity for cross wires to stay the trolley wire going round a curve. The columns and brackets for supporting the trolley wires in Hanover are richly decorated, but are unnecessarily heavy in design, and too close together. The cars have one motor, and the usual controller at each end.

Hamburg.—The tramways of this city are electrical, on the overhead system, with a street mileage of 49·7 miles, containing about 87 miles of tramways track. There are about 300 electric cars at present running, and there will be shortly about 400. Each car without passengers weighs about six tons, and contains only one motor. The steepest gradient is 1 in 20. Electric cars traverse all the principal streets of the city, some of which are comparatively narrow. Cross wires with rosettes are freely used, and where difficulty occurs in placing the latter long lengths of the trolley wires are successfully kept in position by single-wire slanting stays. There appears to have been no difficulty in obtaining the consent of the owners to the placing of the rosettes on the adjacent buildings. The electricity to run the tramways is supplied from two powerful installations vested in the municipality in separate portions of the city. These stations also supply the power for public electric lighting. One of these stations, in the neighbourhood of the Binnen-Alster, contains powerful vertical triple-expansion engines driving directly on the dynamos, with accumulators capable of storing 12,000 ampere-hours at 110 volts. These accumulators provide the supply from midnight to 1 p.m. next day. The newer station in another district of the city contains three triple-expansion engines of marine type of 1,000 h.p. each. There are five boilers to supply these engines, and five more are being erected. The feeder to supply the trolley wire is placed in the carriageway near the footway. The switch arrangements on the ground floor of the engine-house regulate the supply to the tramways, and those on the upper floor for public lighting. Current for lighting purposes is also supplied, being produced at high tension (2,500 volts, with alternators) in this station and transformed to low tension by district or house transformers. The current from the Binnen-Alster station is sent out for lighting purposes only on low tension (240 volts).

Berlin.—About 12½ miles of electric tramways are about to be constructed in Berlin, for the most part overhead, the rest being on the conduit system. The drainage of the conduit will be into the sewers, which are considerably above the level of the River Spree. A power station, belonging to a separate company, will supply power for the tramways. The underground conduit will be 2ft. deep. It has been arranged by the municipal authorities that at least 10 per cent. of the tramways will be on the underground system.

Dresden.—Besides the electrical overhead tramways in Dresden, a tramway has been running for two years by gas traction. The charging of the cars with gas takes place at one of the termini, and occupies about two minutes, the gas being equal to seven atmospheres. This charge lasts for about one hour, at the end of which there are still two atmospheres' pressures, assuming the cars to have gone at the rate of about eight miles per hour. The actual speed of the cars, however, appeared to be at the rate of about six miles per hour. The cars each weigh about 3·8 tons (without passengers), and they are eight in number. The objectionable features of these cars seem to be: (1) unsteadiness of motion; (2) knocking heard from the engine when car is stopped; (3) smell of the exhaust from the gas-engine; (4) the waste of running engine during stoppages.

Vienna.—A small electric railway (the second ever made in Europe), about three miles in length, is working in one of the suburbs of the city; but up to the present overhead wires have not been introduced within the central portion of the city bounded by the "Ringstrasse." There is, however, a new length of electrical tramway commenced outside this portion. In the suburbs two electric accumulator cars ran for some time alternately with steam trams, but are now off. It is expected, however, that they will be placed on again shortly with improved accumulators.

Budapest.—The electric tramways in this city are, with one exception, entirely on the conduit system. The invert of the conduit is about 22½in. from the surface of the rails. The bed or under side of the conduit is about 4in. deeper. Access can be had to the conduit about every 109·3 yards for the purpose of snow cleansing. The conduit or channel is solidly constructed. At intervals of about 4ft. there are placed cast-iron frames, each weighing about 1¼cwt., having in the centre a hollow of the exact shape of the conduit, which is built up in concrete from frame to frame. To these frames are fastened two girder rails, the distance apart being 1½in., forming the slot through which the collector works. The width of the slot, however, increases with wear, and in some places is as much as 1⅞in. wide. In the older portions of the line contact is made with two lengths of angle iron fixed to insulators, one on each side of the iron frame; but a new and improved insulator and contact iron has been adopted for the new portions. One length of iron conveys the electrical energy from the works, and the other forms the return current. Every insulator in the conduit can be examined from the surface by the opening of a small plate. There appears to be little or no difficulty in draining the conduit in Budapest, as the lowest streets are a very considerable distance above the level of the Danube. The power station for driving the tramway system and for lighting the city is furnished with compound condensing engines, driving the dynamos direct. The station contains four engines of 200 h.p. each and three new engines of 600 h.p. each. The tramway supply is sent out at 300 volts. The supply for two district lighting stations is sent out at 3,000 volts, with transformers giving out 110 volts. The boilers for supplying the engines each have 2,906 square feet heating surface. There were 100 cars running last year, but the number has been increased to 150. A new electrical tramway in tunnel is approaching completion from the central portion of the city to the exhibition, to be opened this year. The contact in this case is obtained from an overhead iron rail in the tunnel. A suburban electrical tramway on the overhead system is worked on the route leading to the city cemetery.

Birmingham.—In Birmingham, besides the horse cars, there are steam tramways worked by accumulators. The permanent way is vested in the Birmingham Corporation, and repaired by them at the companies' expense. The gauge throughout is 3ft. 6in., and part of the line originally made to the English railway gauge was converted to this narrow width. The steam tramways have a five minutes' service, the cable trams about a two and a half minutes' service, and the accumulator cars have about a fifteen minutes' service.

General.—After a minute examination of the various systems of mechanical traction obtaining in the cities they have visited, and a careful study of their adaptability to the particular physical and other conditions relating to Belfast, your deputation have come to the conclusion that electrical traction, under certain conditions, is best suited to the wants of the public and requirements of the city. They believe that any unprejudiced person, after having visited the leading European cities, could come to no other conclusion. The objectionable features in connection with steam or gas as a motive power are too great to allow of their being recommended in any known form. The difficulties that would be encountered in introducing an underground conduit system to the lower portions of Belfast, having regard to the position of sewers, covered river courses, gas and water mains, the relation of street surfaces to high-tide level, and the necessarily wide groove required in the rails, are so great that the deputation cannot recommend its adoption. The most extensive conduit system is at Budapest, and the engineer there stated that, whilst it generally worked satisfactorily, there had been interruptions of the traffic owing to the flooding of the conduits, although there was no difficulty from an engineering point of view in regard to drainage. Although your deputation feel that very fair results have been evidenced in connection with the running of cable tramways where traffic is heavy, their mechanical features are such as to render necessary extreme accuracy in time of the tramway service problematical, and they, therefore, could not recommend their adoption. After having carefully weighed the question as to certain central portions of the city being dealt with by means of accumulator cars, they have arrived at the conclusion that to introduce such a system as separately working the central portions of the city, or even as in Hanover, working the cars interchangeably by accumulators and the trolley wire, would not give public satisfaction. Having regard, therefore, to the fact that all practical objections to the overhead system have been surmounted, and that any exceptions thereto from an æsthetical point of view have been reduced to an almost infinitesimal quantity in the best examples of the overhead system, the deputation feel perfectly confident that they are doing the right thing in recommending that system, with certain stipulations, as the best and most suited to the public interest. They recommended also that any proposition made for the conversion of the Belfast tramways on these lines should be subject to the following conditions: (1) All columns, feeders, pipes, wires, brackets, and rosettes shall be in such positions and of such pattern, material, and strength as may be approved of by the Corporation or the city surveyor, and such of them as require shall be painted at least once in every year with good oil paint of colours likewise approved of. (2) No column, bracket, or electrical plant shall be used for the display of advertisements without the consent of the Corporation. (3) Where centre columns are erected they shall be protected with raised fenders to be approved of by the Corporation or their surveyor, and the width of the centre way between the two tramway tracks shall be carefully considered. (4) If any column, bracket, or overhead wire after it has been erected shall, in the opinion of the Corporation or their surveyor, be an obstruction to the traffic, the company shall remove it or alter the

Digitized by Google

position thereof in such manner as the Corporation or their surveyor shall approve. (5) The company shall, in executing any work, take such precautions and do such acts as the Corporation may require for preventing injury to any sewer, pipe, electric wire, or conduit, gas-pipe, lamp-post, or other property belonging to the Corporation or other public authority. (6) Existing paving stones, concrete foundations for same, macadam and its stone or other foundation, where used by the company, shall be paid for by the company to the Corporation, the value thereof being assessed by their surveyor. (7) The centre way, tramway tracks, and 2ft. on each side of same shall be kept in repair by the company, same as the present tramways. (8) All manholes and ventilating shafts and their covers on the site of the new tramway paving shall be altered by the company, or at their cost, so that the covers may be outside the tramway paving, in order to keep the tramway track open at all times, the shafts being altered to suit the new arrangements, and any interference with sewers, drains, gas-pipes, water-pipes, electric mains, and other subterranean works, whether vested in the Corporation or not, that may be disturbed or altered by reason of the alteration or reconstruction of the tramways, shall be executed by the company to the satisfaction of the surveyor, or, failing the work being done to his satisfaction, the city surveyor, after giving one week's notice to the company in writing, may, on behalf of the Corporation, execute such works as are necessary by reason of such interference, and the cost thereof shall be chargeable to and paid by the company. (9) Special arrangements, approved of by the Corporation or their surveyor, shall be made to carry the wires, feeders, and other appliances along the various bridges over the River Lagan, its tributaries, and the various railways. (10) Any officer of the Corporation or member of the fire brigade may at any time, if deemed by him necessary for the public safety, or in case of fire, remove any overhead wire. (11) The Corporation shall be empowered to purchase the electric plant of the company at the end of the present term of 14 years at its then value without any allowance for compulsory purchase, goodwill, or other consideration. (12) The tramway company shall pay the cost of altering the fire-escapes rendered desirable on account of the introduction of overhead wires and stays in connection with the electrical lines. (13) The tramway company shall afford facilities and allow the Corporation to use their poles for lighting purposes, and make their poles suitable for that purpose if desired. The deputation could not fail to observe in the various cities they visited that along what may be termed the suburban electrical tramway routes there is in nearly every case a rapid development of residential and other property, and a consequent enhancement of the value of the adjacent lands. They also remarked the facility with which trailer cars are attached to the motorcars to accommodate additional passengers when required, but more than one such car should not be permitted to be so attached. The deputation were continually struck with the fact that electrical traction can be worked by comparatively unskilled labour, with the greatest precision and delicacy of movement, and under the most perfect control. The deputation were satisfied of this by practical demonstrations, and the facility by which steep gradients can be mounted and descended. In Havre and Brussels they were driven at great speed, and, whilst doing so, the cars were quickly stopped, and even reversed without inconvenience. Their strong impression is that the travelling public are perfectly satisfied and even delighted with this mode of transit. This is evidenced in a marked manner by the quickness of the service and the manner in which the cars are filled.

INSTITUTION OF CIVIL ENGINEERS

PROPOSED ALTERATION OF BY-LAWS.

In accordance with the resolution passed at the special general meeting held on February 6, a petition was duly presented to her Majesty for a supplemental charter to enable the votes of members not actually present at meetings to be taken into account in the election of the council, and to authorise the enlargement of the council, and the appointment of four past-presidents as extra members of the council. The charter has now been granted, and this will necessitate an immediate alteration of certain sections of the by-laws, which will have to be sanctioned at a special general meeting of corporate members. This meeting has been called for Wednesday, April 15, at 3 30 p.m., when the new by-laws given below will be discussed. In addition to the above matters, it is proposed to consider the advisability of commencing the session one week earlier and terminating it on the last Tuesday in April, and, if such alteration be approved at the general meeting, to modify the by-laws accordingly. The alterations to the existing by-laws are as follows:

Section VI shall be intituled "Constitution of Council," in lieu of the present title.

The following shall be substituted for Regulation 1, and the first clause of Regulation 2 and Regulation 4 of Section VI.: (1) The number of the council shall be such as the council in any year may fix for the ensuing year, provided that such number shall not be less than 23 or more than 31 inclusive in both cases of the president and vice-presidents, but exclusive of such of the past-presidents, if any, as may be appointed by the council. The president, the four vice-presidents, and other members of the council (exclusive of past-presidents, to be appointed by the council) shall be elected annually, and the council, when elected for the year, may appoint any number of past-presidents, not exceeding four, to be members of the council for the same year. (2) At an ordinary meeting at least four weeks before the annual general meeting the council shall present a list of persons whom they nominate as suitable for the offices of president, vice-presidents, and other members of the council for the ensuing year, exclusive of past-presidents to be appointed by the council when elected. The list shall include the names of not less than seven corporate members who have not served on the council during the current or the preceding year, and the number of names in all shall be at least two in excess of the number of the council to be elected. The list so presented shall be the balloting list for the annual election on the last Tuesday in May, unless that Tuesday shall be Whitsun Tuesday, in which case the annual election shall take place on the first Tuesday in June. (4) At the ordinary meeting next before the annual general meeting the members shall choose two or more persons as scrutineers for the purposes of the ballot. The balloting list shall immediately after the ordinary meeting at which it has been presented by the council be issued to all members in the United Kingdom, and to any other member residing elsewhere, who may, in writing, request to have the list forwarded to him, and shall be returned to the secretary, at least three days before the annual general meeting in a closed envelope. The scrutineers shall open the envelopes and count the votes and report the result at the annual general meeting. Any balloting list on which a member has voted for a number either more or less than one person as president, four persons as vice-presidents, and the prescribed number of persons as other elected members of council, shall be rejected by the scrutineers.

That the following consequential alterations be made in the by-laws and regulations—that is to say: In Section II., Regulation 8, the words "and other members of the council to be elected or nominated under the by-laws," shall be substituted for the words "and 15 other members of council, being 20 persons."

Section IX. shall be intituled "Proceedings of Council," in lieu of the present title, and Regulation 1 of the same section shall be erased.

That the following further alteration be made in the by-laws: In Section III., Regulation 11, the words "In case the expulsion of any member, associate, or honorary member shall be judged expedient," shall be omitted and the following words shall be substituted: "The council shall have the right, by a majority of two-thirds of those present at a meeting of the council, to expel from the institution any member or associate who may be convicted, by a competent tribunal, of felony, embezzlement, larceny, or misdemeanour, or other offence which, in the opinion of the council, renders him unfit to be a member; and in case the expulsion of any member or associate shall be judged expedient on any ground whatever."

COMPANIES' MEETINGS AND REPORTS.

WILLANS AND ROBINSON, LIMITED.

The fourth half-yearly meeting of this Company was held at the Cannon-street Hotel on Wednesday, April 8, the chair being taken by Mr. Mark Robinson, M.I.C.E. There were also present Sir Gilbert A. Clayton-East, Bart; Captain H. Riall Sankey, R.E. (retired), M.I.C.E., etc.

The report and balance-sheet, which were published in our issue of April 3, were taken as read.

The **Chairman**, in moving the adoption of the report, said: Gentlemen, again the directors are able to address you in terms of congratulation. When the report was written we could only say that in less than three months the orders had reached 22,200 h.p.; we can now say that in three months they actually reached 24,400, or some 28 per cent. more than in the whole 12 months of 1893, itself the record year up to that time. Omitting the Thames Ditton freehold, which follows a practically uniform rule, the value of our plant and machinery and patents at the beginning of 1895, plus the additions to them during that year, was £60 600, and from this sum we wrote off no less than £6,703, or between 11 and 12 per cent. on the total. Yet our plant and machinery are kept in first class condition out of revenue. It has been the steady object of the directors for some years past to promote a demand for the Willans engine in much larger sizes, so soon, that is as we may be in a position to supply them. We are glad to say that among the recent orders is one for four engines of 1,100 h.p. each, to be made, of course, at Rugby. We have an engine of 750 h.p. on order for electric lighting, for one of our municipal bodies, and two of 600 h.p. each for another. An engine of 750 h.p. and another of 700 h.p. are on order for driving mills on the Continent, while nearly 40 engines are on order of sizes from 300 h.p. up to 500 h.p. In fact, the average size of the engines ordered in the first quarter of 1896 was not less than 263 h.p. The development of the really large engine waits, of course, the completion of the new works. We had hoped to be almost commencing work at Rugby by now; we shall not do so until the year is far gone. We have had to modify

Digitized by Google

the plans, in the sense of enlarging them, while the work was in progress, and to commence additional shops. Of the cost of the new works, and of the plant required for them, it is still early to speak with exactness. If no substantial additions become necessary we may expect the cost of land, buildings, fencing, tramways, drains, levelling, etc., to be about £50,000, in addition to £9,800 which had been spent up to the end of 1895. The plant required for the buildings as now planned, including, of course, not only machine tools, but such plant as engines and boilers, electric lighting and power plant, shafting and pulleys, cranes and overhead travellers rolling-stock and fire appliances, will probably cost us fully £30,000 beyond what had been spent up to December last, and including an allowance for various things which it is not desired to order until we are actually at work at Rugby. The two sums added together make £80,000 still to be spent, but it is evidently necessary to allow a margin beyond this. The existing company paid the old company £148,500 for its business, and the present paid-up capital, £225,000, exceeds this sum by £76 500. We have to account for not only £76,500, but also for £13,269, which is the amount we have reserved out of our earnings during the two years to cover the assumed depreciation of our premises, plant, and patents, but which, nevertheless, has remained in the business, and has been at our disposal to spend. We have also to account for £1,130 which we have received under the system of workmen's bonds We have to account, therefore, in all, for £90,899. Of this £33,476 was absorbed, as was intended, in paying off the mortgage debt, the debenture debt, and a banker's loan, transferred from the old company, and a half-year's dividend to the old shareholders. The present balance-sheet shows that at the end of December we had in hand, in cash or investments (not including the reserve fund investments), the sum of £15,823 over and above £11,832 profit carried forward for distribution to shareholders or to reserve. We also spent during the two years £29,235 upon additions to premises, plant, and patents. The three amounts together come to £79,543, which leaves us out of the total of £90,899 a balance of £12,365, which, subject to some minor corrections, is the increased amount which has been absorbed into the floating capital of the business during the two years of fast-growing work. It need not be said that as between the floating capital which with difficulty sufficed us in December, 1893, and that likely to be required by the business we may expect to develop within the next two years at Rugby, a greater difference than £12,000 will be necessary. We have to provide not only for a great increase in the engine business, but we hope for a wholly new as well as large business in Niclausse boilers. The directors feel that any loss of interest caused by borrowing a few thousand pounds more than may be immediately required, is unimportant in comparison with the advantage which attaches to the command of ample funds. The directors are not at present disposed to recommend an issue of more than £75,000 to form part of an issue which may be increased later to £100,000, subject to an undertaking, to form one of the conditions of the issue, that the total issue shall at no time exceed one-third of the paid-up capital, whatever the latter may be, and shall never, of course, exceed £100,000 The authority to borrow up to £112,500 in all, proposed in the resolution, is necessary in order to give power to the directors to obtain small loans (as from the Company's bankers) in the ordinary course of business. There is one point upon which the directors are very willing to pledge themselves—namely, that no money shall be borrowed without the institution of a sinking fund for its complete repayment within the agreed term of years. Allusion has been made to the Niclausse boiler. The delay in making it upon a large scale is not wholly an evil: it has enabled us to test it by extended use in various places before pressing it upon public acceptance. It has borne all tests most admirably. One electric lighting company which lately had two boilers from us has ordered three more, and quite enough are on order elsewhere to afford a most thorough trial. Arrangements have been made with the Admiralty for the manufacture of a set of Niclausse boilers for H.M S "Seagull," under royalty, by Messrs. Humphrys, Tennant, and Co., and the same eminent firm are also making other Niclausse boilers under license from us. So far as we can foresee, this business promises very well indeed.

Mr. Willcox seconded the motion, and the report was unanimously adopted.

The **Chairman** proposed that a dividend at the rate of 6 per cent. per annum on the preference shares and 7 per cent. per annum on the ordinary shares be declared.

Mr. G. W. Ande son seconded, and the motion was carried.

Sir Gilbert Clayton-East moved, "That the directors be, and they are hereby, authorised to borrow for the purposes of the Company, any sum or sums of money not exceeding £112,500 to bear interest at such rate, to be secured in such manner, and to be issued on such terms, as the directors may determine."

This was seconded by **Mr. Anderson**, and carried.

The auditors were elected, and a vote of thanks to the chairman having been passed, the meeting terminated.

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

The annual general meeting of the shareholders of this Company has been held at Pontypool, Mr. W. Pegler presiding. The directors' report stated that since the last report the Company had obtained a provisional order giving them an extended lease of their undertaking for a period of 42 years, but had to consent to clauses being inserted therein giving the local authority liberty to purchase the undertaking at the end of each seven years of the term, the purchase-money to be ascertained by two valuers, who, in arriving at the valuation, are to take into consideration the amount of the capital expended by the undertakers, and, in addition, in respect of the goodwill, a sum equal to the total net profits of the undertaking for the five years immediately preceding their purchase. Since the last report several new customers had been added to the Company's mains, there being 54 different connections attached to the Company's system, and there are others now being made, and the directors consider that the prospects of the Company are very promising. From the accompanying accounts it appears that the working of the station for the year ending December 31, after having carried a sum of £67. 10s. to the renewal account, has resulted in a net profit, which, with the balance carried forward from last year, amounts to £230. 4s. 3d. Of this the directors recommend that a sum of £50 be carried to the reserve fund, and that a dividend of £3 per cent. should be declared on the share capital of the Company, and that the remainder be carried forward to next year's account.

The report was adopted, on the proposition of **Mr. Pitten**, and a dividend at the rate of 3 per cent. per annum was declared.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadrath, Prague.

Luttre (Belgium). - Tenders will be received until April 15 for the construction of an electric generating station at the Luttre Railway Station. Particulars are obtainable at the Bourse, Brussels.

Elberfeld.—Tenders are wanted by April 20 for the supply of four engines and dynamos and 174 lampe, conductors, etc., for the Prussian State Railways. Address, die Königliche Eisenbahn-Direktion, Elberfeld, Germany.

Bucharest.—The Postal and Telegraphic Administration of the Roumanian Government desires tenders by April 18 for the supply of 60,000 porcelain insulators (three sizes) and 10,000 porcelain shackles, for the State telegraphs.

Harrogate.—The Corporation want tenders by April 13 for steel roofs, girders, etc., for the electricity generating station on the Corporation farm, near Harrogate. Particulars may be obtained from Mr. Samuel Stead, borough surveyor.

Vienna.—Tenders are wanted by April 15 for the supply of fastenings and tubes for an extension of the Vienna telephonic system. Particulars can be obtained from the Austrian Administration of Posts and Telegraphs, Section 13, Vienna.

Bedford.—Tenders are wanted for the supply of vulcanised rubber cables for the Corporation's electric lighting. Particulars can be obtained on application to the town clerk's office, Town Hall, Bedford, and tenders must be sent in by the 21st inst.

Chateau Chinon (France).—Tenders are wanted by April 19 for engineering and electrical work in connection with waterworks at Château Chinon, in the department of the Nièvre. The estimate is 43,750fr. (about £1,750), and particulars are obtainable at the Mairie, Château Chinon.

Blackpool.—Tenders are wanted by April 11 for all work necessary for the provision of foundations for one engine and a condenser at the Corporation's electricity works. Particulars may be obtained at the office of Mr. John Hesketh, borough electrical engineer, West Caroline-street, Blackpool.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of articles and material necessary for the upkeep of their electric lighting. Tenders must be sent to the chief engineer, at the company's stores at Santa Apolonia Station, Lisbon, by May 6, and particulars can be obtained there, or at the company's Paris offices, Rue de Châteaudun 28.

Bedford.—Tenders are wanted by the Bedford Urban Sanitary Authority for the construction in various positions in the borough of five underground sub-stations. Plans and specification may be seen at the Engineer's Office, Electricity Works, Bedford, and sealed tenders, endorsed "Sub-Stations," must be delivered at the office of Mr. T. S Porter, clerk, Town Hall, by 21st inst.

Arlon (Belgium).—Tenders are wanted by April 13 for the reconstruction of the locomotive, wagon, and electric lighting shops at the railway station. Particulars at le bureau des Chefs de Service, Arlon, rue de la Station, 36. Also by April 16 for the construction of a reservoir and alterations in the water supply and electric lighting at the Marbehan Station. Address as before.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Edinburgh —Tenders are required by April 11 for the wiring of the police cells, Police-chambers, for the Lord Provost and Magistrates and Council. Specification, forms of tender, and plans of the building can be obtained at the office of the resident electrical engineer, 5, Dewar-place, Edinburgh, on deposit of £2. 2s., which deposit will be returned on receipt of a bona fide tender. Tenders must be sent to Mr. Thomas Hunter, W.S., town clerk, by 10 a.m. on 11th inst.

Digitized by Google

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, 13, Comeragh-road, West Kensington, W., where applicants can obtain a memorandum explaining the local conditions. The tenders will be opened and considered by the Municipality of Lima, which reserves to itself the right of selecting that which is most approved or rejecting all if it thinks fit.

Rathmines and Rathgar.—The Town Commissioners want tenders by April 20 for the electric lighting of the new town hall (about 250 lights, with engine and dynamo), and also for telephones and electric bells Plans and specifications can be seen at the office of the secretary to the Commissioners, Town Hall, Rathmines, Ireland, or copies will be supplied on payment of 10s., and tenders, in sealed covers, endorsed "Tenders for Electric Lighting," must be sent to the above address by April 20 at 10 a.m

Derby.—The Electric Lighting Committee invite tenders for the supply and laying of low-tension cables and junction boxes in the borough. Plans may be seen on application to Mr. J. E. Stewart, engineer, Electric Lighting Station, Derby, from whom a printed form of specification, form of tender, and schedule of prices may be obtained on deposit of £2. 2s. (to be returned on receipt of a bona fide tender). Tenders on the prescribed form must be delivered with the specification attached. enclosed in a sealed envelope, endorsed "Electric Lighting -Tender for Cable," addressed to Mr. H. F. Gadsby, town clerk, Town Hall, Derby, by 12 noon on April 13.

Antrim.--The Commissioners for the Control of Lunatic Asylums will receive sealed tenders up to 10 a m. on May 1 for the supply and erection of an electrical installation at County Antrim Lunatic Asylum. The tender should be sent in a sealed envelope, endorsed outside "Tender for Electric Lighting, County Antrim Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin. and should be accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tenders, and copy of specification, which has been prepared by Mr. J. H. Greenhill, M I E E., will be issued on application to the office of the Board of Control of Lunatic Asylums, Dublin, on deposit of £3, which will be returned to all persons who have sent in bona fide tenders. Plans can be seen at the office of the architect, Mr. John Lanyon, Northern Bank-chambers, Royal-avenue, Belfast.

London —The Shoreditch Vestry require tenders for: (Section A) high-speed engines, electric generators, switchboards, instruments, and street lamps; (Section C) motor transformers and starting switches; (Section D) accumulator battery and stands. All to be delivered and erected complete at the Vestry's electric generating station, Coronet-street, Shoreditch or in sub stations within the parish. Specifications, with forms of tender, can be obtained from Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of £3. 3s., which sum will be returned on receipt of a bona fide tender. Contractors are at liberty to tender for any one of the separate sections or for the whole of the contract, but the Vestry will not consider any tender for a portion only of any of the separate sections. Contractors whose tenders are accepted shall enter into a formal agreement, under seal, with sufficient sureties, for the fulfilment of their respective contracts. Trade union rate of wages and hours to be observed. Sealed tenders, endorsed "Tenders for Contract No. 4," to be sent by 4 p.m. on April 14 to Mr. H. Mansfield Robinson, vestry clerk, Town Hall, Old-street, E.C.

RESULTS OF TENDERS.

St. Pancras (London).—The Vestry have accepted the tender of Messrs. Crompton and Co., Queen Victoria-street, E.C., at £6,456. 17s. 10d., for spare plant at the King's-road electric lighting station.

Halle-a.-S. (Germany).—The lowest tender for the supply of telegraph poles to the Prussian State Railways on March 24 was that of the Berliner Holz-Comptoir, Charlottenburg, at 2·40 marks, 3·15 marks, and 4·20 marks per pole for lengths of 7 metres, 8·5 metres and 10 metres respectively delivered at Crampe or Driesen.

Berlin.—The lowest tender for the supply of 5,000 porcelain insulators to the Prussian State Railways at Berlin on March 25 was that of the Gebr. Rheinstrom at 34½pfg. each, the prices offered varying according to pattern and place of delivery. The lowest tender for 15,400 kilogrammes of 4mm. galvanised iron wire was that of the Westfa. Draht-Industrie, Hamm-i-W., at 13·95 marks per 100 kilogrammes.

BUSINESS NOTES.

Great Northern Telegraph Company.—For the month of March the receipts were £22,400

Western and Brazilian Telegraph Company.—The gross receipts for the week ending April 3 were £2,180.

Bedford.—The Post Office have now completed their local telephone line from London through St Albans and Luton to Bedford.

Parliamentary.—In the House of Lords on March 31 Royal assent was given to the Electric Lighting Provisional Order (Notting Hill, etc.) Act.

Rouen (France).—The National and Colonial Exhibition will be opened on the 16th of next month, and will contain a section devoted to electric lighting.

Bury St. Edmunds.—The Electric Lighting Committee will recommend the Town Council to adopt an alternating-current system with plant similar to that at Bedford.

Dundee.—A sub-committee of the Town Council having considered the charges made for electric lighting, have reported that they see no cause to alter the charges in the meantime.

Hawick (Roxburgh) —The District Committee have decided to extend telegraphic facilities to Roberton, provided satisfactory arrangements can be made with the Post Office authorities.

Paddington (London).—The Vestry have decided to take steps to obtain a reduction of the price of current per Board of Trade unit from the Metropolitan Electric Supply Company, and with power to act.

Monmouth.—The Town Council have passed formal resolutions accepting the electric lighting scheme as approved by the Board of Trade and requesting an extension of the time granted by the provisional order.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending April 5 amounted to £1,256. as compared with £1,024 in the corresponding week of the previous year, being an increase of £232.

Ludlow (Shropshire).—It was decided at the Council meeting that if the Telephone Company did not make the agreement required of them within 14 days all the wires be removed. It was stated that the company disputed the right of the Corporation as to the wires.

Eccles.—At a meeting of the Electric Lighting Committee a letter was read from the Board of Trade, forwarding their approval of the proposed scheme of electric lighting for the borough, for which an application for borrowing powers had been made to the Local Government Board.

Gunnersbury (Middlesex).—The terms on which the Ealing District Council are prepared to supply current to Gunnersbury require that a yearly consumption to the value of £50 should be guaranteed, as well as the payment of interest and depreciation on the cost of the necessary extension.

Henry Pooley and Son, Limited.—This Company has been registered, with a capital of £100,000, for the acquisition, as a going concern, of the business carried on under the style or firm of Henry Pooley and Son, at the Albion Foundry, Liverpool, and to carry on thereat the businesses of producers and suppliers of electricity, etc.

City and South London Railway.—The returns for the week ended April 5 were £815, compared with £935 for the corresponding period of last year, being a decrease of £120. The total receipts for the half-year terminating as above were £13 471, compared with £13,583 in the same period of the preceding year, being a decrease of £112.

Coupon Payment.—The Submarine Cables Trust gives notice that on and after April 15 the sum of £2, on account of the coupon due April 15, 1896, will be paid by Messrs, Glyn, Mills, and Co., of 67, Lombard-street, between the hours of 10 a.m. and 2 p m. The coupons should be left with the bankers for examination four clear days before payment.

London Tramways —It is stated that a scheme is on foot by which a syndicate of tramway experts and financiers are to acquire and consolidate all the tramways in London, and work them under a lease from the County Council. Should the scheme be carried out, it is intended to substitute some form of mechanical traction for horse traction on all the lines.

Monifieth.—A meeting of ratepayers has been held to consider the question of providing some light for the burgh. Mr. R. S. Barrie, convener of the Lighting Committee, referred to electric lighting, and stated that an installation could be established for £3 500, and light supplied at something like 5s. 3d. per 1,000ft of gas. The subject was adjourned.

Sheffield.—The Sheffield Electric Light Company at the annual meeting decided to issue 3,375 additional shares at 10s. premium. These have been allotted amongst existing shareholders, and it was found that all had been taken up as allotted with the exception of 230. There were applications for 6,000 shares in excess of those at the disposal of the directors.

Eastern Extension, Australasia, and China Telegraph Company, Limited.—In pursuance of the conditions upon which the issue of 5 per cent. Australian Government Subsidy Debentures was made, the numbers of debentures drawn by lot on April 1 will be paid off at par on July 1 next at Messrs. Barclay, Bevan, and Co., 54, Lombard-street, E C , after which date interest on them will cease.

Tighnabruaich (Argyll).—This little watering-place is the first of the Clyde resorts to have the electric light introduced in it. The installation has cost about £500. Altogether some 30 lamps have been erected, six of which are on the pier. The generating plant is situated at the offices of the mansion-house of Mr. Samuel Miller, of Glasgow, who is the laird of the property on which the village is built, and to whose initiative and enterprise the introduction of the light is due.

Personal.—Mr. Wm. H. Booth has resigned his appointment as managing engineer for Messrs. Le Grand and Sutcliff, artesian engineers, and has taken offices at 17, Shaftesbury-avenue, Piccadilly circus, where he will carry on business in steam engineering, water supply, and electrical transmission of power, etc. Mr. Booth has carried out many successful water supply undertakings for railways, breweries, manufactories, and electrical stations, notably for the London Electric Supply Corporation, Deptford.

Digitized by Google

Whitehaven.—At the monthly meeting of the Harbour Commissioners the Electric Lighting Committee reported that they had discussed the letter from Mr. T. Brown, the town clerk, with respect to the agreement for the electric lighting of the harbour, and at an adjourned meeting of the committee it was recommended that the Board adhere to the existing agreement. The minutes were adopted.

Belfast.—At a monthly meeting of the Council the minutes of the Electrical Traction Committee were passed. These minutes contained the following resolution, which was passed: "That we are of opinion that a system of electrical traction would be of advantage to the city if a satisfactory arrangement can be come to with the tramways company, and that a committee, to be now named be appointed to meet the directors of the tramways company and report to the Council in committee"

Rathmines.—At a meeting of the Township Commissioners, the chairman read a letter from Mr. Deverill asking for an interview on behalf of the promoters of the Rathmines Dundrum, and Blackrock tramway. The committee, continued the chairman, had given all the tramway proposals the most careful consideration, and had not been able to come to any definite conclusion. He found under the Tramways Act that the proper way to deal with these matters was to call a meeting of the whole Board as a grand jury. That should be done by public advertisement. A meeting would accordingly be called, when they could receive all the deputations that desired to be heard.

St. Mary Woolnoth (London).—In the Court of Chancery on April 1, before Mr. Justice Kekewich, was heard the case of Brooke *v* the City and South London Railway Company. This was a motion by the plaintiffs, the rector and churchwardens of St Mary Woolnoth, the well known City church, for an injunction to restrain the defendant company from proceeding on their notice to treat for taking the church for the purposes of their railway. The defendants having filed an affidavit which the plaintiffs desired time to answer, his lordship directed the motion to stand over to the first motion day next sittings. Mr. Warrington, Q.C., and Mr. R. F. Norton appeared for the plaintiffs; and Mr. Cripps, Q.C., and Mr. Ingle Joyce for the defendants.

Glasgow.—The deputation from the Corporation which visited Brighton, Portsmouth, and Edinburgh to make enquiries with a view to the improvement of the street electric lighting reported that they are unanimously of opinion that, for the purpose of giving the most effective illumination and diffusing the light over the largest area without shadow, the overhanging lamp which has been adopted at Brighton is the best. The lamps in Brighton are partly 12-ampere Crompton lamps and partly Brockie-Pell lamps, run at seven amperes each, and they are suspended from an arm extending 6ft. from the pillar into the roadway at a height of 26ft. from the ground. The cost per light per annum for the Crompton lamp is £33, and for the Brockie-Pell lamp £28.

Edinburgh.—The Catholic Apostolic Church in London-street has now been fitted with a complete installation of electric lighting. The installation consists of about 160 lamps of 8 c.p. and 16 c.p. In the sanctuary hidden lights have been introduced into the dome of the baldacchino to give light to the altar and bring into prominence the colours of the marbles, while behind the baldacchino lights are hung to counteract the shadow thrown by it on the circular wall of the apse. The idea of lighting such a large building by lights invisible to the congregation is somewhat bold and novel, but the result has been a complete success. The whole installation has been carried by Messrs. Anderson and Munro, of Edinburgh and Glasgow. The Lighting Committee have resolved to light Candlemaker-row with electricity.

Tunbridge Wells.—At the meeting of the Town Council attention was called to the fact that on one evening recently the street electric lamps had all suddenly gone out, and Councillor Jenkinson asked if it would not be wise to have the gas lamps lighted to meet such a contingency. Councillor Wood assured the Council that the mishap alluded to was exceptional, and it was hoped that no future inconvenience would be experienced as the plant and appliances were more in working order. Councillor Wood moved the adoption of the report of the Lighting Committee, and reported progress with regard to the new system of lighting by electricity, and said it was proposed to extend the lighting improvements to the western suburbs of the borough beyond the Common. After a few suggestions as to the position of lamps, etc., the report was adopted.

Manchester.—At the meeting of the City Council the adoption of the minutes of the Gas Committee was moved by Mr. Alderman Gibson, seconded by Mr. Alderman Higginbottom, and agreed to. They included a recommendation that £1,600 be paid to the Westinghouse Company, Limited, in full discharge of all claims for royalty, present and future, in connection with the three wire and five-wire systems in use in connection with the electric installation in Manchester. Of the five-wire system, it was explained, Manchester was one of the largest users, and the system had proved exceedingly successful and had resulted in the making of large profits. The opinion was expressed that the arrangement with the company—made subject to the condition that the Corporation should not oppose the application for an extension of the life of the company's patents—would be advantageous to the Corporation.

Cardiff.—A special meeting of the Electrical and Lighting Committee has been held to appoint a fitter and engine drivers for the central station of the electric lighting works. Mr. Illtyd Thomas asked if the committee were not acting in antagonism to the advice of Mr. J. H. Hallett, who was of opinion that the engineer at the works should have control of these appointments. They were adopting a principle in this instance which was unbusinesslike and undesirable. Mr. S. A. Brain also thought the officials and not the members of the Corporation should deal with the positions they were now about to fill. The Chairman explained that those appointed would be subject to the engineer, who would deal with them in the event of neglect of duty or incompetency. The committee then proceeded to appoint a fitter, and the majority of the votes being recorded for Mr. W. S. Melhuish, 2, Pembroke-road, Cardiff, he received the appointment. The following were appointed as engine drivers: Messrs. Dan O'Connell, Morgan Hopkins, and Charles Collier, Cardiff.

Bolton.—Judging from the tone of the remarks made at the last meeting of the Council, Mr. Rider appears to be leaving with the good wishes of the whole of the members Councillor Proctor viewed with considerable alarm the fact that the Gas Committee were changing their electrical engineer at this particular juncture, and he felt it must be a source of regret to every member of the Council that a gentleman who had served the Corporation so faithfully and well was about to leave them. It was well known that Mr. Rider designed and carried out the electrical works, and that they were a credit alike to the engineer and to the Corporation. Some of the councillors seemed to think that if Mr. Rider had waited a little while he would have got a substantial advance in his salary, and they regretted that he should have resigned because his application was not then granted. On the other hand, it was said that when they had a good man they should have kept him; and some very pertinent questions were asked as to why the committee in advertising for a successor should have offered the very same salary they refused to Mr. Rider.

Bradford.—The *Bradford Observer* says complaints are occasionally to be heard from electric light users in Bradford with regard to the durability of their lamps and fittings since the introduction of the higher-pressure supply (230 volts instead of 115, as formerly); but they seem rarely to get as far as the engineer's department at the Town Hall, and when they do the explanation is found in unsatisfactory workmanship in the interior fittings, for which, of course, the Corporation is not responsible. There is now in the market an ample supply of lamps for the 230-volt pressure, which is coming rapidly into vogue in other parts of the country. But the smaller lamp producing firms have not yet taken up this line, as the demand is comparatively new; and it is quite possible, therefore, that purchasers who take any kind of lamp which is pressed on their attention may be supplied with 230-volt lamps of inferior quality. Upon this same topic, it will be noted that the Leeds City Council is taking up decisively electric propulsion of its trams; and Bradford, as recent remarks of the chairman of the Tramways Committee indicate, is not likely to linger longer than it can help behind Leeds in this matter.

Padstow (Cornwall).—At the meeting of the Urban District Council the Vice-Chairman called the attention of the Council to the installation of the electric light at Mevagissey. For lighting that town with 34 lamps during 10 months of the year the Parish Council were going to pay only £48, whereas in Padstow £60 per year was paid for about seven months. From calculations and enquiries he had made, the streets of Padstow could be lighted, as now, if the town possessed electric plant, for less than £30, a saving of one-half or more, and almost sufficient to pay the interest on the capital necessary, a little over £1,000. In his opinion, electricity was not only the illuminant, but the motive power of the future; and if the Council were to erect machinery for its manufacture, it would be a profitable undertaking, and add greatly to the financial and general prosperity of the town. An abundance of light at a reasonable price and an adequate water supply were two essentials to the well-being of a town, particularly to one claiming to be a health resort. If water and the electric light were introduced at the same time the expense would not be very heavy, and ultimately both prove paying concerns.

Lambeth (London).—Messrs. Julius Sax and Co. have been selected by the Electric Lighting Committee of the Lambeth Vestry to receive the provisional order for electric lighting. The whole of the scheduled streets are to be laid with mains, the charge is to be not more than 6d. per Board of Trade unit, and a dust destructor is to be provided. The firm have agreed to maintain and supply current to 25 arc lamps, in such positions in the compulsory streets as the Vestry may direct, free of charge. The period to be mentioned in the transfer agreement will be 31 years from the date of the agreement. At the end of 21 years the Vestry will have the right to purchase the undertaking at 25 per cent. above the then value as determined by arbitration. Messrs. Sax have agreed to treat all parish refuse at 1s. 6d per ton in the destructor. This is 8d. cheaper than under the present system. Messrs. Manlove, Alliott, and Co. will be responsible for the destructor, and Mr. R. W. Weekes, A.M.I.C.E., A.M.I.E.E., the consulting engineer, will have charge of the electric lighting. There is some discussion as to whether the dust destructor shall be adopted in conjunction with the lighting scheme of Mr. Sax; but in the event of its being rejected Mr. Sax reserves to himself the right to charge 6½d. per unit for the electricity supplied to consumers.

Cheltenham.—The General Purposes Committee have instructed the electrical engineer to proceed with the work of wiring the Council-chamber, mayor's room, committee-room, and the rate and water offices so far as the same can be done at a cost not exceeding £50. The Lighting Committee have received a report from the borough surveyor on the lighting of the south ward, in which he suggested that the 12 lamps now standing between Thirlestaine-road and the Norwood Arms should be

Digitized by Google

replaced by electric incandescent lamps as an experiment, and the electrical engineer having reported that this could be done at a charge of £3 per lamp so as to return a small profit to the electric light department and secure a large increase in the illuminating power it was resolved that as soon as the consent of the Local Government Board had been received to the extension to Thirlestaine House the suggestion should be carried out. The report of the electric inspector of the result of his tests of the supply of electricity during the month shows an average of 103 volts, the legal standard being 100 volts for low pressure cables. The electrical engineer has obtained quotations for the supply of service cable during the remainder of the year, and recommends that all service cable required be obtained from Callenders. The number of 8 c p. lamps connected to the mains was about 6,150, and the number waiting to be connected about 700.

The Central London Railway. – A case in which the Kensington Woodhouse Park Syndicate, Limited, claim £32 790 as compensation from the Central London Railway Company for the compulsory acquisition of their property has occupied Mr Under-Sheriff Burchell and a special jury for two days at the Sheriffs' Court, Red Lion-square. The estate in question is situated at Shepherd's Bush, and covers an area of 10 acres. It is required by the Central London Railway Company for the construction of a terminal and generating station for the new underground line which they are about to lay from Shepherd's Bush across London to the City. The plaintiffs claim that their property is of exceptional value for exhibition purposes, to which use it has been already put. The defendants, on the other hand, point out how unsuccessful financially exhibitions already held in the West of London have been. The claimants are represented by Mr Littler, Q.C., and Mr. Edmonston, whilst Mr. Freeman Q.C , and Mr. Boyle appear for the railway company. A number of witnesses have been called on behalf of the claimants to prove the value of the property to its owners both for exhibition purposes and for development as a building estate. Mr. J. Hart, who had been officially connected with the Empire of India Exhibition, stated that the site at Shepherd's Bush was wholly unsuitable for the purposes of an exhibition, and if the experiment was tried he felt sure large sums of money would be dropped. After further evidence, the case was adjourned to 18th inst.

Pemb oke (Dublin).—A special meeting of the Commissioners has been held for the purpose of considering the scheme of tramway extension and alterations promoted by the Dublin United Tramways Company, and embodied in their memorial to the Lord-Lieutenant in Council, and also another scheme of tramways extensions promoted by the Rathmines, Dundrum, and Blackrock District Tramway Company. Mr. Manly, the secretary, submitted the notice of the scheme of the Dublin United Tramways Company, setting out the various proposed lines. The scheme includes lines on the Pembroke-road, Clyde-road, Wellington-place, Waterloo-road, Anglesea road, Stillorgan road, Eglinton-road, Milltown-road, Ringsend road, Bridge street, and Thomas-street, Ringsend; Irishtown road, and Upper Baggot-street. The secretary also read the notice of the Rathmines, Dundrum, and Blackrock District Tramways Company, which proposes to run over Milltown-road and Eglinton road. He stated that the solicitors for the Southern District Tramways Company were under the impression that the present meeting was the enquiry contemplated by Section 5 of the Tramways Act of 1860, at which all parties could be heard by the Board as a grand jury. The secretary further explained that the law adviser had given it as his opinion that this was not so, and, having informed the Southern Tramways Company that such was the case, they had lodged a memorial with the Board complaining of non-compliance with the statutory requirements on the part of the United Tramway Company. A formal resolution was passed disapproving of the proposed order.

Lincoln.—The Special Electric Lighting Committee having considered the question of producing electricity in the city had engaged Mr. J. Hopkinson, D Sc., F.R S., etc., to inspect the city and report. They had considered his report, and recommended that it was advisable to supply electricity in the city, and that in their opinion the most advantageous means of providing such supply would be the system described in the report made to the committee by Dr. Hopkinson. They requested to be empowered to take such steps and proceedings as were necessary in order to vest in the Corporation the powers of the Electric Lighting Acts. At the meeting of the Council Alderman Page, in moving the adoption of the report, said the consideration of the subject had led the committee to the unanimous conclusion that if not during the first few months, at any rate during the early period, the undertaking would be self-supporting if the initial cost was not extravagant. He contrasted the high-tension alternating system with the low-tension continuous current, and said that the committee had received valuable statistics from a vast number of towns, and almost without exception—in fact, it was almost universal—that within a period of three years the electric lighting system was self-supporting, and demands for the current increased greatly. They might easily embark on finding the sum of £15,000 which would be necessary for the installation. If the Corporation empowered the committee to set to work, they would find a site and then make recommendations as to the method of carrying out the proposal. Mr. Turner seconded, and the report was adopted

Newcastle-under-Lyme.—Major Marindin, R E., inspector of the Board of Trade, who, a few weeks ago, held an enquiry as to the objections of the Corporation to the provisional order applied for by the promoters of the Potteries Extension Tramways, empowering them to construct a line between Newcastle and Hanley, *vid* Etruria, has forwarded his report to the Council. He comes to the conclusion that in some respects the objections lodged by the Town Council to the laying of the tramway within the borough had been shown to be well founded, and that the promoters had failed to establish their contention that the assent of the Town Council to the making of the tramway according to the present scheme and without any modifications of the order should be dispensed with. He considered that the scheme did not offer advantages which Newcastle might fairly claim, inasmuch as it merely provided a route between Newcastle and Hanley, and did not facilitate communication between Newcastle and the districts surrounding it. With regard to the tramways asked for by the Town Council to Silverdale, Chesterton, Wolstanton, and Trent Vale, he thought that the first two were the most essential, and that the third should be undertaken if the tramway between Wolstanton and Burslem be made, as this would supply a want and provide a through route from Newcastle to Burslem and Goldenhill; but he did not think that a case had been made out for a tramway to Trent Vale The Council were clearly not adverse to tramways, and a large majority of the ratepayers desired them, and he therefore considered that if the promoters would consent to be bound by a clause with the following conditions, the construction of the proposed tramway within the borough of Newcastle should be sanctioned, and the assent of the Town Council dispensed with if after further consideration of the terms proposed they did not decide to give it. The clause he suggested was that the promoters being given power to construct the tramway should be bound not to use this power so far as that part within the borough of Newcastle was concerned until they had obtained powers to construct tramways to Silverdale and Chesterton, and had exercised those powers. They should also give an undertaking to promote a tramway between Wolstanton and Newcastle if they exercised their power to construct a tramway from Burslem to Wolstanton.

International Electric Railway Prize Problem.—The president of the commission in charge of the design and construction of the mountain railway in Switzerland to the top of the snow-clad Jungfrau Mountain has issued the following information concerning the prizes offered for the solution of certain problems involved in the construction of this road. The total sum of the prize offered is 30,000fr. (£1,200) for the best solution of a number of questions which are involved in the construction and operation of this road. The chief points involved are the following: (1) in the laying out of the road—the profile of the tunnel, the roadbed and elevated structures, the rails, rack, switches, and crossings, the best system for transmitting the electrical energy, protection against interruption by atmospheric conditions, rolling stock, project for the construction of the station and restaurant at the Eiger Glacier Station, design of the station (presumably near the top), which is to be bored out of the solid rock, an elevator of a height of 100m. and 8m. in diameter to the top of the mountain; (2) in the construction of the road—methods of boring the tunnel, and all problems connected therewith; (3) in the operation of the road—precautions and devices for assuring continuous operation and preventing interruptions, methods of lighting and heating the tunnels, cars, and stations. Solutions of one or more of these questions may be offered by single individuals or by several collectively; solutions of other questions not enumerated which are deemed of importance in the construction of this road, will also be accepted. The Scientific Commission will decide on the value of the answers, and their results will be published. By offering the prizes the company reserves the right to adopt the solutions for which prizes are offered without further cost on this road only; solutions which do not receive prizes will be returned. The following information is added: the maximum grade is 25 per cent. the gauge 1 metre, the smallest radius 100 metres, the smallest "ausrundungsradius" 500 metres, the greatest width of rolling-stock 2·50 metres, and the greatest height 3 metres, the allowable speed 7 to 10 kilometres per hour. The water power for generating the current amounts to about 5,000 h.p, and will be taken from the two Luetchinen; from the turbine to the beginning of the road the distance is about 8 kilometres, and from there to the beginning of the tunnel 2·5 kilometres; the tunnel has a length of 10 kilometres. Applicants for prizes should send drawings or models, if necessary, as also estimates of cost. Papers will be received up to August 1, 1896. Further information may be obtained from the Bureau der Jungfraubahn, Bahnhofstrasse 10, Zurich, Switzerland.

Leeds.—At a meeting of the City Council a long discussion took place on the proposed electric tramways. Mr. Willey called attention to the following letter, written to the chairman of the Highways Committee (Mr. Hannam) by Dr. Hopkinson with regard to the construction of the tramways: "Dear Sir,—My terms for preparing specifications and supervising the carrying out of the works in connection with your proposed system of tramways in Leeds would be 5 per cent on the cost of the work up to forty thousand pounds (£40 000), and 4 per cent. on anything beyond that sum. It would be understood that this commission would only extend to such parts of the work as you might think fit to put in my hands, that I should bear all my own costs, whether for assistance or for travelling, that the Corporation should provide and pay their own clerk of works, and that from the commission first payable the sum of five hundred pounds (£500) should be reserved for the purpose of paying for my services in generally advising as consulting engineer for one year after running had begun, and to be payable at the end of that year. I understand that in the event of my being appointed it is the intention that the whole of the electrical work should be placed in my hands, including the cars and the engines, and the

Digitized by Google

buildings, laying of the road, etc., would be done by yourselves. But, of course, in that event, I should be very willing to give the necessary indications as to space to your engineer, and should be glad to look at the plans before they were carried out, with a view to making any suggestions which might occur to me.—I am, dear sir, yours truly, J. HOPKINSON. P.S.—These terms are independent of, and in addition to, the fee now payable to me for my report.—J.H." Mr. Hannam in replying, said the committee asked to be allowed a free hand in the matter. They had a system in view which they believed would be the best, either in this country or out of it. With regard to Dr. Hopkinson's appointment, he thought that a matter which ought to be left in the hands of the committee, who would carry out the enterprise at the lowest cost. The question of fares had been thoroughly discussed by the committee, and it was felt that Leeds was behindhand in the matter of penny stages. The reduction of fares and a quicker service on the Hunslet and Kirkstall lines had resulted in an increase of between £20 and £30 a week in the receipts, and he thought the traffic would be trebled in consequence of the reduction now proposed. The complaints made as to delays on the different lines should be brought before the committee. The minutes of the Highways Committee were adopted, and thus the Council approved of the terms contained in Dr. Hopkinson's letter, with the exception of that relating to the work connected with the engines and cars being placed in his hands. The adoption of penny stages on the Chapeltown and Headingley routes was also likewise sanctioned.

Llandudno.—At a special meeting of the District Council, the report of Mr. A. H. Preece on the establishment of an electric supply station combined with dust destructor and electric tramways was submitted. Mr. Preece said he had carefully considered the probable immediate demand, and he estimated that it would be sufficient if plant were installed for about 4,000 8 c.p. lamps burning at one time; that would be equivalent to about 6,000 lamps fixed in consumers' premises. The question of the system to be used depended entirely on the position of the generating station. The report estimated that the cost of the installation would be £20,500; that the annual working expenses would be £2,085; and the revenue £3,250. The gross profit would be £1,165 and after deducting for interest and sinking fund about £1,100, the net profit would be about £65. In dealing with electric lighting combined with a refuse destructor, Mr. Preece estimated that the cost of the combined scheme would be £23 400, £2,900 in excess of the electric supply station alone Therefore, estimating the destructor at £3 700 by itself, about £800 would be saved by combining the two plants. In reporting on the addition of an electric tram scheme to the above, Mr. Preece says: "I feel sure that a tramway at Llandudno along the parade to Craigside and along Mostyn-street at any rate would be of great advantage to the electricity supply station if it were called upon to supply energy for the purpose, but whether the Corporation lay down and equip the tramway themselves or leave it to a company is a matter which is entirely for them to decide. In this report I do not propose to go into the policy and probable cost or financial gains which would be made from the tramway; the point which I wish to show is that the establishment of an electric tramway in Llandudno would be of appreciable advantage to the electricity supply station, and it would tend to reduce the cost of the electric light. The additional capital expenditure required to make the necessary provision for tramways would be £4,600." In conclusion, Mr. Preece says: "I recommend the committee to adopt the second scheme, and to consider the necessary steps to be taken so that the second scheme may be enlarged ultimately to enable electrical energy to be supplied to a tramway as in the third scheme. I feel confident that a triple scheme as described will be a certain success. The reduction in the cost of electricity supplied to private consumers is bound to lead to an increased demand for light, and in the near future you will be in a position to supply light at an exceedingly cheap rate. The cost of street-lighting by arc lamps will be small, and the finances would be greatly improved by the profits which are certain to arise from the successful administration of those local industries." It was decided to hold a special meeting to discuss the proposals.

Brighton.—At a meeting of the Lighting Committee a letter was received from the Glasgow Police Commissioners (Lighting Department), a deputation from which recently visited Brighton, asking for certain information with regard to the public lighting by electricity, and adding: "Our committee were very much struck by the fine appearance of your pillars." At the meeting of the Town Council, Councillor Stafford moved the adoption of the proceedings, and said he understood the Glasgow Committee were paying Brighton the compliment of imitation in street-lighting, and he thought it something to be proud of. The proceedings were confirmed. The Lighting Committee submitted a report by the electrical engineer with reference to raising additional capital for the purposes of the electricity undertaking. As showing the rapid extension of the demand and use of electricity in Brighton, he submitted figures showing that the number of consumers was as follows: March 23, 1892, 100; March 23, 1893, 226; March 23, 1894, 454; March 23 1895, 872; March 23, 1896, 1,121. It appeared also that this rate of increase was likely to be maintained, as the rate of receiving new applications for the supply this year was more than 85 per cent. greater than in the corresponding period of any other year. The most sure sign of the healthy development of the business, however, was the increasing rise in the sales of electricity year by year. These had been (excluding all electricity used in public lamps): 1892, 22,000 units; 1893, 44,000 units; 1894, 78,000 units; 1895, 148,000 units; 1896, 228,000 units. These figures, Mr. Wright holds conclusively proved the commercial soundness of the policy pursued by the committee in constantly extending the electric mains in all directions within the borough, in arranging the tariff so as to enable the small householder to derive the benefits of the electric light as readily as the rich, and in gradually increasing the size and capacity of the generating station so as to enable it to cope with the increasing demand. He thought it would interest the committee to learn that the cost of producing electricity in Brighton in 1895, exclusive of coal, the cost of which depended so much on the geographical position of the towns compared, was again lower than that of any other town in England whose accounts had as yet been published Mr. Wright proceeded to point out the need of fresh capital for house service, meters, extending mains, etc., and for additional plant in the generating stations. He estimated that £23,000 would be required for fresh capital on electricity works accounts, and £4,500 for work in connection with street lighting, making a total of £27,500 The committee concurred in the recommendations of the engineer, and recommended that application be made to the Local Government Board for sanction to borrow the sums of £23,000 on the electricity works account for a period of 25 years, and £4,500 on the district fund account for a period of 15 years. Councillor Stafford, in moving the adoption of the report, said it was so comprehensive as to need few words from him. There was no doubt the success of the electric light in Brighton was largely owing to the adoption of street-lighting. It was his privilege last week to visit a generating station in the North of England, where the engineer regretted very much he could not make the lighting profitable, as the Council would not adopt street-lighting. Since the street-lighting the applications to the committee had increased greatly, and even since the report they had had 84 applications, as against 45 in any previous year. The motion was seconded, and carried unanimously.

Newington (London).—Major Philip Cardew, R.E., has held an enquiry on behalf of the Board of Trade to hear objections to the provisional order which is being promoted by the Newington Vestry with the object of obtaining powers under the Electric Lighting Acts to supply electricity in the parish. Mr. Morton W. Smith, barrister, appeared for the Vestry in support of the order. Mr. Wheeler, Q.C. and Mr. T. Dale Hart, LL B, represented the Newington and Walworth Ratepayers' Association. Counsel also appeared for the two companies who have lodged objections to the Vestry's scheme. Mr. Morton Smith explained that when the Electric Lighting Acts were first passed, in 1882, it was proposed that only one authority or one company should exist in one area. The Newington Vestry in 1883 contemplated applying for a provisional order, but in consequence of opposition the matter dropped. In 1888 a new Act was passed in favour of competing orders. Thereupon a number of provisional orders to supply Newington were applied for, and one was secured by the London Electric Supply Corporation, but up to now this company had only laid down a few mains. Last year or the year before the County of London and Brush Provincial Electric Lighting Company applied for a provisional order, but as the Vestry had expressed the opinion that the power to supply electricity ought to be reserved to the local authority, the Board of Trade declined to allow the company's application to be proceeded with, so that the Vestry might apply for power to supply the parish. The general idea was that these powers could be better exercised by local authorities for the profit of the ratepayers than by a company. Moreover, the Vestry could supply electricity much cheaper than a company. Against the scheme of the Newington Vestry there had been various petitions lodged with the Board of Trade. The first was that of the London Electric Supply Corporation, the company which obtained an order to supply Newington in 1889. This corporation stated in their objection that they had executed the necessary works and made the necessary arrangements for supplying electrical energy, and were both able and willing to supply all such demands as would arise. They contended that no sufficient grounds existed why further powers should now be granted to the Vestry. In reply to this, the Vestry would point out that Section 1 of the Electric Lighting Act, 1888, was expressly passed to enable the local authority to be granted a provisional order, notwithstanding that some company or corporation had already obtained a license or provisional order for the parish. The corporation in question had only laid mains along the street from St. George's Church, High-street, Borough, down Newington-causeway and Walworth-road to Deacon-street. They had not complied with the terms of Clause 23 of their order, for no main had been laid, so far as the Vestry could ascertain, in Newington-butts, nor to the full extent of Walworth-road, as specified in the schedule—*i.e.*, to Wansey-street. Having failed to carry out their duty under Clause 23 of their order, the corporation was liable to have their order revoked under Clause 25. The second objection was lodged by the County of London and Brush Provincial Electric Lighting Company, who held that the special circumstances of Newington were such that an electrical undertaking limited to that parish could not possibly earn sufficient revenue to pay its expenses, and that the only practicable way of obtaining a supply of electricity for Newington was to make it part of a larger area, such as that now being applied for by the objectors, who were prepared to undertake the supply of electricity in Newington as part of their larger undertaking. The Vestry believed that this company would be equally unable to supply energy at a sufficiently low rate. He now came to the petition of the Newington and Walworth Ratepayers' Association. There was, he said, every reason to believe that the opposition arose from purely interested and party motives. The Vestry admitted it would be unfair to tax all the ratepayers for the

Digitized by Google

benefit of those residing in the main roads. This was not the intention of the Vestry's scheme As the Board of Trade knew, the electrical supply stations in the hands of the local authorities did not prove burdens upon the rates. There was no idea on the part of the Vestry to enter upon this scheme as a speculation. They would be well advised by competent engineers before moving to give effect to the order if granted, and if it should be found after due enquiry and investigation that Newington was a parish in which electrical energy could not be supplied with success then there would be power under the order to contract with a company for the supply. A great number of witnesses were called, and it was stated that the Vestry proposed to spend £28,000 on the undertaking. This sum was made up as follows: land, £1,700; buildings, plant, and works (including generating station), £26,000; and contingencies, £1,000. The capital expenditure was estimated to supply 8,000 or 9,000 lamps. The principal grounds of objection appeared to be that the locality did not require it, that the people would not take the electric light when laid, that the scheme was too incomplete, that it was a speculation, and that the parish was too heavily rated at the present time to be able to bear a further increase. The enquiry lasted three days.

PROVISIONAL PATENTS, 1896.

MARCH 30.

6890. System of distribution of electrical currents. Salomon Berditschewsky, called Apostoloff, 53, Chancery-lane, London.

6925. Electric water gauge. Hermann Biermann, 115, Cannon-street, London. (Complete specification.)

MARCH 31.

6943. An automatic electric light door switch. Walter John Fryer, Danecroft, Silverdale, Sydenham, London.

6958. Improvements in controlling gear for electrically-propelled carriages or trucks. John Dalrymple Bell, 87 St. Vincent-street, Glasgow.

6980. An improved electric boat-propeller. Joshua Entwisle, 5, John Dalton-street, Manchester. (Samuel Newton Smith and E. S. Baring-Gould, United States.) (Complete specification.)

6981. Improvements in electric batteries. Joshua Entwisle, 5, John Dalton street, Manchester. (Samuel Newton Smith and E. S. Baring Gould, United States.) (Complete specification)

6993. An improved coin-freed electric meter. Robert Hacking, 78 Fleet-street London.

7000. A process and apparatus for decomposing sodium or potassium chloride and generating electricity. Ludwig Epstein and Frederich Marza, 28, Southampton-buildings, Chancery-lane, London.

7005. Improvements in electric hammers and the like. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Arthur S. Barnes and Perry S. Skinner, United States.) (Complete specification)

7013. Improvements in electric meters. James Devonshire, 70, Chancery-lane, London. (Charles P. Steinmetz, United States.) (Complete specification.)

7038. Improvements in regulators for electric arc lamps. Hermann Bäurlin, 18, Buckingham-street, Strand, London. (Complete specification.

7054. Improvements in electrical signal systems for railways Louis Charles Werner, 40, Chancery-lane, London. (Complete specification.)

APRIL 1.

7074. An arc lamp for high voltages. Alfred John Beaumont, 6, Scarcroft-road, York.

7121. A new method of making shades for gas, electric, or other lights. Arthur Felix Davies, 82A, New Bond-street, London.

7140. Improvements in mechanism for driving clocks and dials by electricity. Arthur Joyce, 6, Lord-street, Liverpool.

7151. Improvements in differential automatic switches. Francis Henry Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion-street, Clerkenwell, London.

7161. Improvements in or relating to electric light fittings. Frederic Augustus Chapman, 111, Hatton-garden, London. (Complete specification.)

7162. Improvements in or relating to secondary batteries. Alfred Julius Boult, 111, Hatton-garden, London. (Jules Julien, Belgium.)

7166. Improvements in electric fire-alarms. Michael A. Shanahan, 40, Chancery-lane, London.

APRIL 2.

7174. A metal for heating by electricity. John Chester Green, Winnipeg, Manitoba, Canada.

7195. Improvements in dynamos. Sebastian Ziani de Ferranti, 27, Charterhouse-square, London.

7232. Improvements in apparatus for manufacturing tubes by electrolytic deposit. Alexander Stanley Elmore, 28, Southampton-buildings, Chancery-lane, London. (John Oliver Surtees Elmore, India.)

7237. Improvements in electric fire-alarms. Isaac T. Bomar, 40, Chancery-lane, London.

7254. Improvements in electric igniting devices for gas burners. Gottfried Ferdinand Krieger, 45 Southampton-buildings, Chancery-lane, London.

7255. Improvements in secondary batteries. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Jules Julien, Belgium)

7259. Improvements in and in the construction of soluble-metal electrodes for accumulators. William Phillips Thompson, 322, High Holborn, London. (Jules Julien, Belgium)

APRIL 4.

7318. Improvements in electric heaters. Edward Ethel Gold, 55, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1895.

11478. Electrolytical separation of metals from their ores. Johnson. (Pelatan and Clerici.) (Second edition.)

5205. Secondary battery plates. Luckow.

8453. Electric switches. Brockie.

9380. Electric-firing pistols for gun mountings. Lloyd and Brankston.

9442. Insulating electric conductors. Hardingham. (Felten and Guilleaume.)

9504. Incandescent lamp shades. Barratt and others.

9636. Arc lamps. Siemens Bros. and Co., Limited, and Booker.

10277. Measuring electric currents. Siemens Bros. and Co., Limited, and Lauckert.

11544. Telegraph poles, etc. Bullers, Limited, and Chambers.

21460. Electric motors. Morgan.

24711. Electric brakes. Devonshire. (Potter.)

1896.

474. Electrically-propelled vehicles. Bersey.

780. Secondary electric batteries. Leitner.

3032. Electric railway signalling apparatus. Krapf.

3093. Dynamo-electric machines. Devonshire. (Knight and another)

3094. Regulating alternating currents. Devonshire. (Berg)

NOTES.

Moving Pictures.—Colour has been added to Mr. R. W. Paul's moving pictures.

Copenhagen Academy.—Lord Rayleigh has been appointed a foreign member of the Copenhagen Academy of Science.

The Crystal Palace School.—The distribution of certificates at the Crystal Palace School of Practical Engineering takes place to-day (Friday), under the presidency of Mr. A. T. Walmisley, M.I.C.E.

Copper.—It is stated that in the long-distance plants installed by the General Electric Company in the United States during 1895, over 1,200 miles of copper wire for transmission purposes alone were used, amounting practically to 1,200,000lb. of copper.

Presentation.—On the occasion of leaving the Crichton Royal Institution, Dumfries, Mr. W. B. Edgar has been presented with a handsome gold chronograph by the electrical staff and a few friends. Mr. Edgar, on leaving Dumfries, will join the staff of Messrs. Johnson and Phillips, Charlton, Kent.

Robbing a Tramcar.—According to the *Western Electrician*, the two men who last October "held up"—*i.e.*, stopped—an electric tramcar and robbed the passengers in it between Chicago and Evanston, have been caught, tried, and convicted. The sentence is not stated. It is noteworthy that, in spite of the conviction, our contemporary still speaks of the men as the "alleged robbers."

Military Telephones.—In the *Compte Rendu* of the proceedings of the Société des Ingenieurs Civils de France a communication appears from Captain Charollois on the subject of telephoning through bare wires laid on the surface of the ground. With a 6mm. wire laid through wet grass and an earth return, Captain Charollois obtained perfect communication over a distance of four miles. The details, however, are not given.

Military Telegraphs.—In a serial article on Italian military telegraphs, *L'Electricien* describes the light cable lines used for temporary purposes. These are hung on trees or hedges, laid on the ground, or even when necessary laid beneath it. The core is copper wire, insulated with indiarubber and covered with hemp treated with zinc-white. As long as the covering is in good condition the cable can be taken through marshes and rivers, but for torrents and rapid streams an armoured cable is used.

Imperial Institute.—The exhibition of motorcarts to be held at the Imperial Institute in May and all through the summer months is to include vehicles propelled by steam, oil, electricity, and springs. It will be interesting to see whether examples of the last will be forthcoming; there seem to be difficulties in the way of a clockwork coach outside of toyland. There is also to be a section for apparatus for aerial navigation—in other words, flying machines—and a section devoted to stationary engines, dynamos, and motors.

Voltage Regulator.—The Hopfer and Eisenstuck apparatus for maintaining the voltage constant either at the dynamo or any other point has been described in the *Elektrotechnischer Anzeiger*. It consists essentially of a wire resistance, successive portions of which are brought into the circuit by means of a mercury-cup which is moved up and down below the ends of the wires, each successive one of which is shorter than the preceding. It is operated by a shunt magnet through a system of levers, which are arranged so that they may be accurately balanced by means of sliding weights.

The Iron and Steel Institute.—The spring meeting of the Iron and Steel Institute of Great Britain will be held on Thursday and Friday, May 7 and 8 next, at the Institution of Civil Engineers, Westminster, under the presidency of Sir David Dale. Upon that occasion the Bessemer gold medal, which is awarded annually in recognition of meritorious services in advancing the science or practice of the metallurgy of iron and steel, will be presented to Dr. Hermann Wedding, of Berlin. The list of papers down for reading and discussion is a full and comprehensive one.

A Brilliant Invention.—The application of electricity to heating purposes is a favourite subject for the inventor. The last thing in this way is a suggestion, reproduced in the New York paper *Electricity*, that the drivers of electric tramcars should be kept warm in the winter by a coat having a resisting network of wires woven into it and connected with the trolley circuit. The suggestion comes from Texas instead of one of the Northern states, and it is almost a pity that it is not more practical, if only on account of the beautiful Greek name that would be manufactured for an electric self-heating overcoat.

Lightning Arrester.—A new lightning arrester, designed by Mr. Ohlinger, of Paris, is described in *L'Industrie Electrique*. It consists essentially of about 20 circular plates of tin, insulated from each other by the same number of plates of micanite. These latter are of about 4mm. greater diameter than the tin plates, so that they project and prevent arcing. The plates are perforated in the centre and threaded on a rod, so as to form a vertical cylinder, and the whole is covered with a porcelain bell. The arrester is said to be suitable to both high and low tension lines, and it is said to have been used with tensions up to 10,000 volts.

A Swiss Waterfall Plant.—The *Schweizerische Bauzeitung* gives an account of the utilisation and distribution of energy derived from the fall of La Goule in the Bernese Jura. The area of supply covers about nine villages or small towns. The motive power is derived from four turbines of 500 h.p. each. These are coupled direct to Oerlikon alternators running at 200 revolutions a minute, and supply high-tension current direct to the line. The frequency is 50 and the voltage 5,000, which is transformed to 240 volts on three-wire systems for lighting and to 220 volts for power. The line is carried on wooden posts, and the total length is about 21 miles.

Swedish Exhibition.—According to *Kuhlow's German Trade Review*, the arrangements for the Stockholm exhibition have been completed. It will take place in 1897, and everything is now being done to make it as representative and comprehensive as possible. Matters are being pushed ahead with much vigour, and all parts of the country appear to take the keenest and most active interest in the success of the undertaking. The exhibition will contain sections devoted to engineering, machinery, shipbuilding, electricity, scientific appliances, etc. It is added that the site of the exhibition, about which there was at one time much disagreement, leaves nothing to be desired.

Society of Arts.—The council of the Society of Arts have announced the offer of the Fothergill Prize of £25 and a silver medal for a paper on "The Best Means of Effectually Preventing the Leakage of Current to Earth in Electrical Installations from Generating Heat and Setting Buildings on Fire" The paper should consist of about 8,000 words, and be written with a view to being read and discussed at an ordinary meeting of the society. All papers submitted for the prize should be sent to the secretary before October 1, 1896. They must be type-written, and

Digitized by Google

bear a motto, the name of the writer being enclosed in a sealed envelope with a similar motto in the usual way.

Hungarian Exhibition.—A meeting of the British Committee in connection with the Hungarian Millennial Exhibition to be opened at Budapest on May 2 was held on Tuesday at the Mansion House, the Lord Mayor presiding. The subject of communications and cheap tickets having been discussed, a report on the general progress of the exhibition was submitted by Mr. Felbermann, who stated that it was nearly completed. He hoped that a great many English people would pay it a visit. If they did he could assure them that they would be warmly received by the Hungarians, who entertained a grateful feeling towards the British nation for having been so kind to them in days gone by.

Carbides of Yttrium and Thorium.—Messrs. Henri Moissan and Etard have described the carbides of yttrium and thorium prepared by them with the electric furnace. The composition in each case corresponds to the formulæ YC_2 and ThC_2. Both decompose water, the yttrium carbide giving about three-quarters acetylene and the rest methane with a small quantity of ethylene and hydrogen. Thorium carbide gives more methane and hydrogen, besides a small quantity of liquid hydrocarbons. The colour of the thorium carbide appears to be yellow, but it is liable to be masked by the presence of residual carbon in the form of graphite. With a current of 900 amperes at 50 volts the reduction to carbide of about 2½oz. of oxide appears to have taken four minutes.

Utilising Water Power.—The utilisation of a more or less distant water power for manufacturing purposes by means of electrical plants appears to be making steady progress on the Continent, especially in those countries where cheap coal is not obtainable. In this week's issue of *L'Elettricità* three new installations of this kind are noted in Italy. The first is for a cotton mill at Capriolo, in Brescia, and the distance which the current is conveyed is hardly over 100 yards. The second is also for a cotton mill at Ponte San Pietro, in Bergamo. It is an 800-h.p. plant, and the current is conveyed about 2½ miles, something like 200 h.p. being apparently lost in the process. The last is a small affair of only 13 h.p. on the estate of Prince Borghese, at Fossanova, in the Pontine Marshes. The current is, however, conveyed over three miles, and used for purposes connected with agriculture. In each of these three cases triphase or polyphase currents are used.

Three-Phase Currents.—It is remarked in the *Revue Industrielle* that recent applications have shown the practicability of increasing the range of central stations serving electric tramways by the use of three-phase currents. With a maximum potential of 500 volts, the expense of copper limits the length of the line which can be run from a single generating station, but the difficulty can be avoided by having a number of small sub-stations along the line containing a motor transformer which gives a continuous current at 500 volts, and is worked by a high-tension three-phase current. Our contemporary, after describing the Lowell and Lakeview line, in Massachusetts, and the Dublin, Blackrock, and Dalkey tramways, concludes that this system of working will play an important part in the future of electric traction, "since it supplies a simple, elegant, and practical solution of the problem of communication with villages and places where, on account of its cost, an ordinary railway service would be impossible."

Changing to Three-Phase.—In describing the new work carried out at Bourganeuf, in the department of the Creuse, *L'Electricien* remarks that the conveyance of energy by electricity is progressing slowly but methodically in France. The Bourganeuf installation is about eight years old, and takes its power from the Jarraud cascade, about 8½ miles distant. It has now been completely remodelled to work with three-phase currents and give much greater power, so that of the old work little but the station buildings is preserved. The motive power is derived from two horizontal turbines of 225 h.p. each. Current is generated at 80 volts and transformed to 9,000 volts for transmission along the line, the wires being carried on high poles. At Bourganeuf part of the current is transformed down again to 110 volts, and converted into a direct current for lighting and charging accumulators, and the rest is used to supply power to a paper-mill. For this purpose it is transformed down to 100 volts, and works two three-phase motors of 120 h.p. and 15 h.p. *L'Electricien* considers that this installation as now remodelled is of a type which under many circumstances may render great service to municipalities and manufacturers.

Personal.—The Blackpool *Gazette and News* refers to Mr. J. Hesketh's marriage and his departure for Australia in the following terms: "We must heartily congratulate Mr. John Hesketh, the borough electrical engineer, upon an approaching 'double event.' In the first place, Mr. Hesketh's marriage to Miss Laurie Hinnell, daughter of the town clerk of Bolton, takes place at Rivington on Tuesday, and we wish them every possible happiness. Then this week Mr. Hesketh has received news of his appointment as electrical engineer to the Government of Queensland. Considering that there were over 100 applications for the post, Mr. Hesketh must indeed consider himself fortunate. The commencing salary of the office is £600 a year, with travelling expenses, and Mr. Hesketh's duty will be to advise on all matters connected either with telegraphy, telephones, electric lighting, and electric tramways in this rapidly-growing colony. Mr. Hesketh will have to cover a lot of ground in the discharge of his duties, but he believes that the work will exactly suit him. Mr. Hesketh's resignation of his position at Blackpool has been placed in the hands of the Electric Lighting Committee, and we understand the committee decided to at once advertise for a new electrical engineer in order to allow Mr. Hesketh to leave for Australia within the next three months."

Royal Meteorological Society.—At the monthly meeting of the Meteorological Society last Wednesday Mr. W. Ellis, F.R.S., read a paper on the "Mean Amount of Cloud on Each Day of the Year at Greenwich for Fifty Years, up to 1890," from which it appeared that a principal maximum occurs in winter and a principal minimum in autumn, with a secondary much less pronounced maximum in summer, and a secondary minimum in spring. Cloudless days are most numerous in spring and autumn, and least numerous in winter and summer. Days of "much cloud" are nearly equal in amount in all parts of the year. On the same evening Mr. E. D. Fridlander, B.Sc, gave an account of some observations of the amount of dust in the atmosphere made at various places during a voyage round the world in 1894-5. The experiments, which were made with a form of Aitken's pocket dust counter, showed that there are often considerable variations in the number of dust particles in a very short space of time. Dust was found up to an altitude of 6,000ft. or 7,000ft. amongst the Alps, and also in the open ocean so far away from any land as to preclude the possibility of artificial pollution. Major H. E. Rawson, F.R.Met.Soc., also gave an analysis of the Greenwich rainfall records from 1879 to 1890, with special reference to the declination of the sun and moon.

Niagara Electric Tramway.—The Americans are not backward in the provision of means of access to beautiful

Digitized by Google

scenery, even if the beauty is not particularly improved in the process. For instance, the current issue of the *Scientific American* contains a description of an electric tramway that has been built along the gorge below Niagara Falls. It is called the Gorge electric railroad, and is worked by the Niagara Falls and Lewiston Railroad Company, and operated in connection with the hotel and observation tower which have been erected by the same company in the village of Niagara Falls, near the State Reservation. The entire length of the road, from Niagara Falls to Lewiston, is about seven miles. Each car has two 50-h.p. Westinghouse motors and electric heaters. The power is now supplied by the Niagara Falls Hydraulic Power and Manufacturing Company, utilising the water from the Schellkopf surface canal at 210ft. head. Two Westinghouse 50-h.p. generators supply the current at 500 volts potential. The line is laid with 60lb. steel rails, double tracked throughout, with trolley wire of 00 gauge. With the exception of the descent from the high land to the river, the maximum grade is 1¼ per cent. The line forms a terrace on the side of the cliff, and is usually about 25ft. above the water-level. Nevertheless, it appears that the spray from the rapids frequently falls on the cars.

The Slide Rule.—We have before us a copy of the second edition of Mr. C. N. Pickworth's excellent little book on the slide rule. This was duly noticed in our columns at the time of its first issue, and therefore nothing more need be said than that the only material alteration in the second edition consists of the rectification of the few errors that have been detected in the work. The form of slide rule dealt with is the Gravêt or Mannheim type, which contains on the front two pairs of logarithmic scales, of which one pair is double of the other, and a metal "cursor," and on the reverse side a scale of equal parts and scales of log. sines and log. tans. When accuracy is not required within 1 per cent. in the result, it is extraordinary the amount of computation that can be done with an instrument of this class. There has always been a fight between the four-figure logarithm table and the slide rule, and in the nature of things it is somewhere about there that the transition from computation by the rule to computation by tables must necessarily take place. It is noteworthy, however, that the disadvantage under which the rule stood for operations involving continuous multiplication has been greatly removed by the adoption of the "cursor," and, indeed, this is one of the marked advantages that this type of rule has over the older forms. The use of rules of this type is extending in this country, though somewhat slowly. There can, however, be no doubt that they only require to be more widely known and better understood to be largely adopted.

Stealing Electricity.—The New Jersey Senate on the 18th ult., by a unanimous vote, passed a Bill to prevent people stealing electric current from the wires. The Bill reads as follows: "Any person who shall unlawfully or maliciously displace, remove, injure, or destroy any line of electric lighting wire or cable, or the material or property belonging thereto, without lawful authority, or who shall unlawfully and wilfully cut, break, tap, or make connection with any electric lighting line or cable, or who shall aid, agree with, employ, or conspire with any person or persons to unlawfully do or permit or cause to be done any of the acts hereinbefore mentioned, shall be deemed guilty of a misdemeanour, and on conviction thereof shall be punished by a fine not exceeding 500dol. or imprisonment at hard labour or otherwise not exceeding two years, or both. Any person who shall wilfully, with intent to injure or defraud, connect a wire or other instrument or contrivance with a wire used for conducting or supplying electricity in such a manner as to supply such electricity to any lamp wherein the same can be lighted or used without passing through the meter or instrument provided for registering the quantity consumed, or who shall wilfully, with intent to defraud, obstruct, alter, injure, or prevent the action of any meter or other instrument used to measure or register the quantity of electricity consumed in a house, shall be guilty of a misdemeanour, and on conviction thereof shall be punished by a fine not exceeding 500dol. or imprisonment at hard labour or otherwise not exceeding two years, or both."

The General Electric and Westinghouse Combination. — We have in a previous number given particulars of the mutual arrangement entered into by the General Electric Company and the Westinghouse Electric and Manufacturing Company in America. The matter has naturally occupied the attention of the technical Press, and the comments upon it are not on the whole unfavourable to the combination. For example, the New York *Electrical Review* says on the subject that "at the first glance this arrangement is liable to impress the small manufacturer in the electrical field as an attempt to form a trust to which he is not a party and which will eventually drive him out of the business. Assuming as true the statement that there is no consolidation of the two companies, and we so believe, the patent basis on which the deal is formed certainly makes them a very powerful competitor of every other manufacturer in the field. No doubt there will be a few of the smaller manufacturers who will find it impossible to compete against such power, but we predict that those who fall by the wayside will not be the companies who have been doing business on business principles, even if only in a small way. In the long run we believe this agreement will be a good thing for the whole industry. It is impossible for any one company or any two companies to secure all the business, or even the lion's share of it. The growth is too rapid and competition is too keen for this to be done. We believe that the small manufacturer who has been doing business on business principles will not only not be disturbed in his work, but will also profit through having a number of unstable competitors cut off, who will find it impossible to compete where he, as a business man, can compete and make money even against the alliance the General Electric and Westinghouse Companies have made." The argument is not quite clear, but the feeling is evident.

Alternating Systems.—Mr. Ernest Scott does not like alternating systems and has written to the *Leeds Mercury* to say so. He does not "envy anyone the position of assistant in an alternating-current station, such as the City of London Company's station at Bankside," and thinks that there must be "something radically wrong about a system which is not supplied with some method of storing the energy required." Continuous-current stations, he adds, "such as St. Pancras, St. James's and Pall Mall, Westminster, Hull, Bradford, etc., are all fitted with accumulators, which automatically take up the change in the load, and the plant generally is more reliable, to say nothing of a minimum risk to life." Mr. Scott then continues: "In a paper which my partner, Mr. Addenbrooke, read before the Institution of Electrical Engineers a few weeks ago it was shown that with the high-voltage lamps (220 volts) which are now on the market, the economical area of supply with continuous currents can be extended from 1½ miles square to five miles square. Now, a square which is five miles along each side will more than cover the area of our largest towns. Another interesting fact is that, owing to patents expiring and increased competition, the manufacture of accumulators has been greatly improved,

Digitized by Google

whilst the cost per horse-power has come down within the last five years (50 per cent.) to about the same as ordinary plant—engines, boilers, dynamos, etc. It seems to me, therefore, that those gentlemen who have been and are advising towns to go in for alternating-current supply are likely to find themselves in the wrong box, especially so when we consider the demand for electric motors which is bound to take place in a year or so. For long-distance transmission there is, of course, a large field for alternating currents, only in that case it will have to take the form of two or three phase currents (in order to give a sufficient torque to the motors), and not single phase, as is in use at Leeds, Sheffield, Burton, etc."

Motors for Factory Work.—Commenting on an article by Mr. W. Baxter on the subject of driving machine tools in factories by electric motors rather than by shafting, the New York *Electrical World* says in factory management the cost of production must be reduced to a minimum and the adoption of newer and more expedient methods must constantly be studied. In the case of factories already in operation, the question of discarding long lines of shafting and directly applying motors to the individual units is a serious problem, to which no general statements or conclusions are applicable. "There, are, however, in most factories many points in common, and to these cases more or less general statements can be made. For instance, there can be no question as to the advisability of directly applying motors to large machine tools where current is available, or where several such units distributed about a factory warrant the installation of a generator; or, in case the buildings are separated, to transmit power electrically from a central point. As soon as this is decided, the question immediately arises as to what shall be the minimum size of motor used and to what extent shall individual tools be individually supplied. A study of the particular conditions presented in each factory can alone decide this problem, for it can be stated with certainty that the use of a number of extremely small motors will, in general, not be advisable owing to their inefficiency, increased cost per unit of output, and greater liability to damage. Cases can be imagined where the use of such might to some extent be warranted, yet the question would still arise whether a general grouping driven from one or more countershafts would not be more expedient." A more important point than this would seem to be whether the tools run constantly or only occasionally as required, since the economy of the electric motor comes in from the fact that the load ceases when the tool stops, while the shafting keeps running. Mr. Baxter, however, considers that the use of motors in factories has but just begun, and the future promises an extensive increase in their direct application to machine tools.

Rontgen Radiations.—Mr. H. Becquerel has communicated to the Paris Académie des Sciences some experiments on the difference between the invisible radiations emitted by uranium salts and the Röntgen rays. The former suffer double refraction and polarisation. Messrs. Benoit and Hurmuzescu also stated that the effect of the new radiations in discharging an insulated metal plate varies according to the metal of which the plate is composed. The same is the case with the ultra-violet rays, but the order of the metals is not the same in the two instances. Messrs. Abel Buguet and Albert Gascard state that the Röntgen radiations will at once distinguish between ruby, sapphire, emerald, topaz, and cats-eyes, and their glass imitations. Turquoise is similarly distinguishable, and the curious organic salt of aluminium, mellite, is nearly, as transparent as carbon. In fact, the comparative transparency of metallic aluminium to the Röntgen rays seems to be preserved in all its salts. The doings of Mr. Edison are written about in such a strange way that care has to be exercised in reproducing anything relating to his work from the American Press. One of his undoubted discoveries is, however, that calcium tungstate forms a good fluorescing substance to use for making the new rays visible. It may not be so good as potassium platino-cyanide, but it is very much cheaper, and is preferable for other reasons. But it seems from a letter sent by Mr. T. E. Espin, F.R.A.S., not to a technical paper, but to the *Newcastle Daily Chronicle*, the effect is not quite the same. "Photographing pieces of zinc, tinfoil, and silver with a screen of calcium tungstate before the plate the rays are shown to have penetrated them. With a screen of barium platino-cyanide the images appear." This result is worth further investigation, as if confirmed—and there is no antecedent improbability in it—it points to the existence of something equivalent to undulations of different periods being contained in the Röntgen rays. Nothing further has been heard from the owners of the mysterious plate-box which has special properties in connection with these radiations. Their experiences are doubtless reserved for the next issue of *Knowledge*. As for the theory of the subject it will be time enough to go into that when something definite has been determined. At present it will be sufficient to caution readers against accepting statements that the Röntgen rays cannot be infra-red or ultra-violet radiations because their properties are not the same. All the properties that have been investigated relate to radiations which lie comparatively close to the visible spectrum, and would probably be quite different when the dimensions of the wave become extreme in either direction. It is obvious, for instance, that when the wave is no longer large compared to the atom that a very different state of things will prevail.

Institution of Civil Engineers.—Sir Benjamin Baker presided at the dinner of the Institution of Civil Engineers held on Tuesday in the Queen's Hall. There were a very large number of members of the institution and guests present, including the American Ambassador, the Duke of Teck, Mr. Goschen, M.P., Sir Redvers Buller, Lord Medway, Lord Balfour of Burleigh, Mr. Shaw-Lefevre, M.P., Mr. Bryce, M.P., Sir A. Arnold, Mr. Courtney, M.P., Sir F. Abel, Major-General Sir Charles Wilson, Sir G. Molesworth, Sir E. H. Carbutt, Sir M. Ommaney, Sir D. Galton, Mr. A. J. Barry, Mr. J. W. Barry, Sir Lowthian Bell, Mr. Brunel, Mr. H. Brunlees, Mr. J. Brunlees, Lord Colville of Culross, Prof. Dewar, Mr. Grierson, Mr. Hawkshaw, Mr. Woods, Mr. Maudslay, Mr. Pember, Mr. Pope, Mr. Preece, Mr. Siemens, and others. Mr. Goschen, in replying to the toast of "The Army, Navy, and Auxiliary Forces," said at this moment in every assembly of Englishmen the toast of "The Navy" was received with almost unusual enthusiasm. He took no narrow view of the great profession to which his hosts belonged, for it rested with them to lay down the lines on which civilisation was to advance in various parts of the world. Every great undertaking of this country was associated with engineering enterprise, and it was the engineers who were opening out to the influences of civilisation the continent of Africa. For the navy the work of the engineer was one of paramount consideration. He had no remorse on account of the enormous demands which he had felt it his duty to make on the present Chancellor of the Exchequer, and he was not sorry that of the vast sums which the House of Commons had cheerfully voted for the navy no inconsiderable portion would flow into the coffers of members of the Institution of Civil Engineers. He

Digitized by Google

saw amongst them those who made the gigantic armour-plates which protected our ships, those who made the guns and the machinery of our great vessels of war, and those who were mainly responsible for the new class of torpedo-boat destroyers which played so considerable a part in the naval construction of the day. Engineers had done and would do much for the navy, but every invention made that which existed obsolete—and obsolete was a terrible word. There were certain things, however, which did not become obsolete—the courage, the energy, the foresight of the men who manned our ships. The inventiveness, not only of Englishmen, but of others, sometimes placed the Admiralty upon the horns of a dilemma. The Admiralty was sometimes reproached with being unwilling to accept improvements, and sometimes denounced for accepting new inventions too rapidly. Many civil engineers would have been interested in the great controverted question of water-tube boilers. He ventured to think that the experience of foreign countries had shown that this was an invention which deserved the best consideration of the Admiralty. One of the leading features of modern naval programmes was the new class of torpedo-boat destroyers. These had been built by English enterprise and English skill, and were considered to have a great success at the Admiralty, and had achieved the astonishing speed of 29 to 30 knots. Such an invention as this was not to be laid up in cotton wool. It was the duty of the Admiralty to test by experiment, and they were training as many men as they could to try these boats which could accomplish the distance between Holyhead and Dublin in an hour and 50 minutes—about half the usual time. He envied the science of the engineers who were able by experiment to test principles, whereas the politician could never tell whether a measure would be successful or not. The politician attempted to apply a principle, but he could never gauge the result or discover whether his experiment was successful or not. The foundations might be insecure, and the building tumble down, and no one know the cause of the failure. It was the same with economic science, and oftentimes it was impossible to say whether the material of the attempted structure was bad or its original foundation insecure. But the engineer could always follow the application of his theory and test it by the result of experiment. Our statesmen had but one consolation, and that was that our rivals on the Continent were in precisely the same condition as ourselves. Subsequently, Lord Balfour replied for the "House of Lords" and Mr. Courtney for the "House of Commons," and the American Ambassador responded to the toast of "Our Guests," while Mr. Bryce proposed "The Institution," to which Sir Benjamin Baker (the president) made due acknowledgment.

The Metric System.—The articles in the *Times* on the metric system which we referred to last week have naturally called forth a correspondence on the subject. Little new, however, has been said. Either people are weary of the question or the matter has been already thoroughly threshed out and it only remains to take a decision. Mr. Samuel Montague, the president of the New Decimal Society, naturally writes in support of the object of his association. One point made is that while some of the opponents of the metric system object that it would prevent the use of quarters, others complain that they actually are used in the United States, where the decimal system is adopted for money. Mr. Montague admits that "if the whole world could start afresh, a perfect duodecimal system might be universally adopted, but nature, in giving us 10 fingers instead of 12, decided long ago in favour of decimals," and while the advocates of a duodecimal scale are "dreaming about an arithmetical millennium, if that decimal term can be applied appropriately, we are suffering loss and inconvenience at home and abroad." Mr. Emerson Dowson, the chairman of the Executive Committee, repeats the well-known arguments in favour of the adoption of the system. Mr. Robert Kaye Gray, having apparently never heard of the "metric ton" of 2,204lb., objects that "as the greatest weight mentioned in the metric system is the myriagramme of approximately 22lb., this system is unserviceable for dealings in large weights," such as a truckload of coal. Lord Grimthorpe can generally be depended upon to say something vigorous in a controversy of this kind. He remarks that anything beyond making the metric system "lawful for any persons who like to buy and sell or make contracts by it would be a piece of gross tyranny, such as pertinacious prigs sometimes manage to inflict on an enormous majority who are too lazy to fight them, or do not understand what they are doing. The metre never made any way even its native country till that breed of men forced it down the public throat. Just now some commercial ones want to do it in order to save themselves trouble in dealing with metrified countries, and do not care how much they give to everybody else." Lord Grimthorpe, however, will have nothing to do with duodecimals. "The duodecimal system is only fit to go on being set as a mathematical question, as it used to be 60 years ago, in spite of some theoretical advantages. If the founders of arithmetic had been Goliaths with 12 fingers, probably we should have had it." Mr. J. C. Stevenson says that "surely it is far-fetched remedy for the want of enterprise of our foreign traders that all our home traders and the whole internal trade of the country, wholesale and retail, should be compelled to abandon" the old measures. If the measures in use in this country were more uniform, there would be much force in this. His other objection is a sentimental one—namely, the disuse of the English names of weights and measures, those "grand old Saxon monosyllables, which are as old as the English language and the inheritance of the Anglo-Saxon race throughout the world." Some of them are not "Anglo-Saxon," but that does not much matter for the purposes of the argument. Mr. C. Harpur says that "the use of sixteenths and thirty-seconds in Stock Exchange quotations and rupee rates is not an argument against decimalism, but merely an illustration of the fact that the ordinary man only looks as far as the end of his own nose. Halving and quartering is simpler than dividing into tenths, so most people take the former way, forgetting that it leads them inevitably to sixteenths and thirty-seconds. When they reach these latter they wish they had taken the other way. Most people in the City agree that exchange rates would be much easier to work with if expressed decimally; but they do not express them decimally, because no one can start without the consent of all the rest." Lastly, an anonymous correspondent remarks that "it is pretty easy to work out mentally the value of, say, a yard and three-quarters of riband at 3½d. a yard, while it is very difficult to work out mentally the value of, say, 1 metre 75 centimetres of riband at 35 centimes a metre." There is nothing to prevent him working the second problem in the same way as the first if he likes. The fact that the yard is divided into 3ft. has not prevented him using quarters of a yard. Curiously enough, everyone has shirked the question of the division of the angle which is hopelessly mixed up with the measure of time. But the only "practical" man concerned in this matter is the sailor, and he settled the matter long ago by using a mile of his own which has no relation to the statute mile.

THE ROYAL COLLEGE OF SCIENCE.

It was announced on Wednesday that the Lord President of the Council had appointed Prof. J. Perry to the

PROF. PERRY.

vacant Chair of Mechanics and Mathematics at the Royal College of Science.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XXVII.

(Specially Contributed.)

THE INDUCTION OF CURRENTS BY MOTION OF MAGNETS—NOTIONS ABOUT MAGNETIC LINES OF FORCE—MAGNETO-GENERATORS FOR ELECTRIC BELLS—SIMPLE DESCRIPTIVE KNOWLEDGE OF THE COMMON SORTS OF DYNAMOS AND ALTERNATORS.

Faraday's Paper of November 21, 1831.—Two names of departed physicists have always occupied a place in my mind, which would indicate me a thorough-going hero worshipper. These names are those of Faraday and Tyndall. I was never much of a biologist, hence Huxley is not to me so great a hero as the men I have named. Faraday's researches must always possess a fascination for students of electrical science, and Tyndall's "Heat a Mode of Motion" was a revelation to me as a young student, and the interest excited by its study was afterwards largely increased by hearing the voice and seeing the experiments of this great teacher. There are living physicists who, to me, ought to be characterised as heroes, but through some mistaken freak of fashion it is not customary to tell your heroes that you admire them as men, writers, or teachers. You must wait to worship till they are dead and cannot be cheered by a knowledge that their labours are appreciated.

Faraday was a physicist in the truest sense of the word. And I feel I cannot do better than to introduce this part of my subject in his own words, given in his memorable paper of November 24, 1831. This paper is divided into four sections: § 1. On the induction of electric current. § 2. On the evolution of electricity from magnetism. § 3. On a new electrical condition of matter. § 4. On Arago's magnetic phenomena. As regards the first section, this forms part of the subject-matter of our next chapter. The second section of the paper, however, is now our study. In it Faraday says:

"A welded ring was made of soft round bar iron, the metal being $\frac{7}{8}$in. in thickness and the ring 6in. in external diameter. Three helices were put round one part of this ring, each containing about 24ft. of copper wire $\frac{1}{20}$in. thick. They were insulated from the wire and each other, and superposed in the manner before described, occupying about 9in. in length upon the ring. They could be used separately or conjointly; the groups may be distinguished by the letter A (Fig. 1). On the other part of the ring about 60ft. of similar copper wire in two pieces were applied in the same manner, forming a helix, B, which had the same common direction with the helices of A, but being separated from it at each extremity by about $\frac{1}{2}$in. of the uncovered iron.

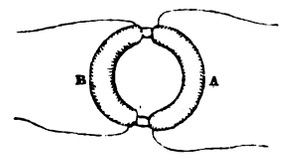

FIG. 1.

"The helix, B, was connected by copper wires with a galvanometer 3ft. from the ring. The helices of A were connected end to end so as to form one common helix, the extremities of which were connected with a battery of 10 pairs of plates 4in. square. The galvanometer was immediately affected . . . but though the contact was continued, the effect was not permanent, for the needle soon came to rest in its natural position, as if quite indifferent to the attached electromagnetic arrangement. Upon breaking the contact with the battery, the needle was again powerfully deflected, but in the contrary direction to that induced in the first instance."

It may be pointed out here that *this simple apparatus of Faraday's was the first transformer* ever made. Further on Faraday says:

"By using charcoal at the ends of the B helix, a minute *spark* could be perceived when the contact of the battery with A was completed."

This was foreshadowing the use of the developed apparatus in the latter years of the century. For historical purposes our next chapter should have come before this, because Faraday shows the difference between the actions of coil on coil with and without the iron core. To return again to Faraday's words:

"Similar effects were then produced by *ordinary magnets*. Thus the hollow helix just described has all its elementary helices connected with the galvanometer by two

FIG. 2.

copper wires, each 5ft. in length; the soft iron cylinder was introduced into its axis; a couple of bar magnets, each 24in. long, were arranged with their opposite poles at one end in contact, so as to resemble a horseshoe magnet, and then contact made between the other poles and the ends of the iron cylinder, so as to convert it for the time into a magnet (Fig. 2); by breaking the magnetic contacts or reversing, the magnetism of the iron cylinder could be destroyed or reversed at pleasure.

"Upon making magnetic contact the needle was deflected. Continuing the contact, the needle became indifferent and resumed its first condition. On breaking the contact it was again deflected, but in the opposite direction to the first effect, and then it again became indifferent. When the magnetic contacts were reversed, the deflections were again reversed.

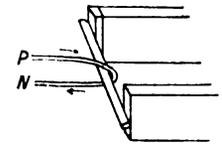

FIG. 3.

"When the magnetic contact was made, the deflection was such as to indicate an induced current of electricity in the opposite direction to that fitted to form a magnet having the same polarity as that really produced by contact with the bar magnets. Thus, when the marked and unmarked poles were placed as in Fig. 3, the current in the helix was in

Digitized by Google

the direction represented, P being supposed to be the end of the wire going to the positive pole of the battery, or that end towards which the zinc plates face, and N the negative wire."

Surely we may consider this *the first alternator* ever made.

We may refer to one other description of apparatus in this remarkable paper:

"A disc of copper, 12in. in diameter, and about ⅛in. in thickness, fixed upon a brass axis, was mounted in frames so as to allow of revolution either vertically or horizontally, its edge being at the same time introduced more or less between the magnetic poles" (Fig. 4). . . . The copper

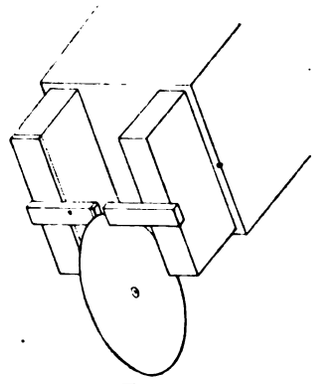

Fig. 4.

disc was adjusted as in Fig. 4, the small magnetic poles being about ½in. apart, and the edge of the plate inserted about half their width between them. One of the galvanometer wires was passed twice or thrice loosely round the brass axis of the plate, and the other attached to a conductor which itself was retained by the hand in contact with the amalgamated edge of the disc at the part immediately between the magnetic poles. Under these circumstances all was quiescent, and the galvanometer exhibited no effect. But the instant the plate moved, the galvanometer was influenced, and by revolving the plate rapidly the needle could be deflected 90deg. or more. . . .

"Here, therefore, was demonstrated the production of a permanent current of electricity by ordinary magnets."

Fig. 5 gives a complete view of Faraday's apparatus, and this was *the first magneto-electric machine* ever made.

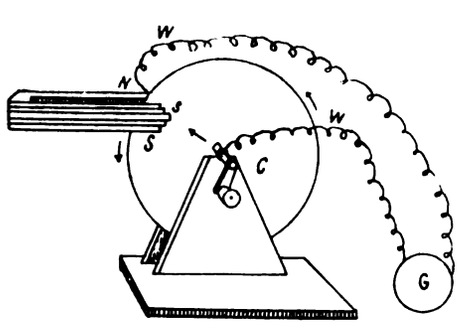

Fig. 5.

Thus Faraday in this one paper broke ground in the applications of electricity which to-day is of overwhelming importance. In the diagram, C shows the copper disc, N S the poles of the permanent magnet. One contact is with the axle of C and the wire of the galvanometer, G. The other contact is with the edge of the disc, C, and the other wire of the galvanometer. When the disc is rotated as shown by the arrows, the current seems to go from the axis to the circumference through wire to galvanometer, and by other wire back to axis, thus completing the circuit.

Pixii.—Faraday's discoveries were soon to bear fruit, and in 1832 Pixii constructed what is usually termed the first magneto-electric machine. Fig. 6 shows this apparatus, which consisted of a strong vertical permanent magnet, of horseshoe shape, capable of being rotated by the wheels and spindle shown. A fixed horseshoe electromagnet had its poles just above those of the permanent magnet. As the field magnet rotates, a current is induced in the coil of the electromagnet, and passes to the external circuit by the wires shown. The fixed electromagnet in this case forms the armature of the permanent magnet.

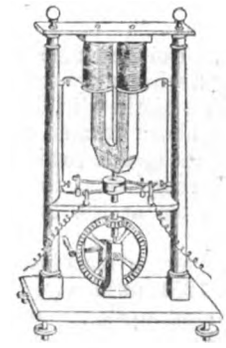

Fig. 6.

Saxton.—Following Pixii, Saxton designed a machine in which the armature rotated while the field magnets remained stationary. Fig. 7 shows the complete machine. Here a compound permanent magnet, A, is fixed in an horizontal position, and as close as possible to the poles an armature consisting of an electromagnet with core of soft iron. The armature is rotated by means of the wheel and strap, F, on to the spindle carrying the armature.

The magnet in Saxton's apparatus was about 7in. long, with a polar air-gap of 2in. In Fig. 7, A is the compound horseshoe magnet, C three insulated helices of copper wire, D a wooden cup containing mercury upon a stand, H. A copper disc, E, dipped into the mercury, and

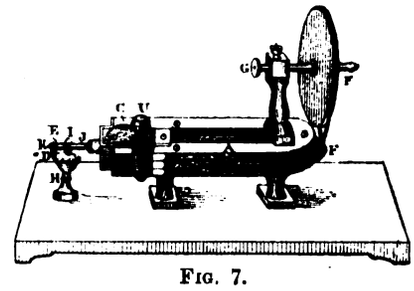

Fig. 7.

was connected to one end of the helices by a brass piece, I. A cross-bar of copper by a screw, J, was connected to the other end of the helices, and was so adjusted that when the revolving armature was at right angles to the magnet poles the ascending point of the cross-bar was about $\frac{1}{20}$in. above the surface of the mercury. The rotation was caused by the wheel and band, F F. The position of the wheel was regulated by the screw G, and thus the band tightened or not as required.

Miller gives the following description of one armature details (Fig. 8): It "consists of two straight pieces of iron

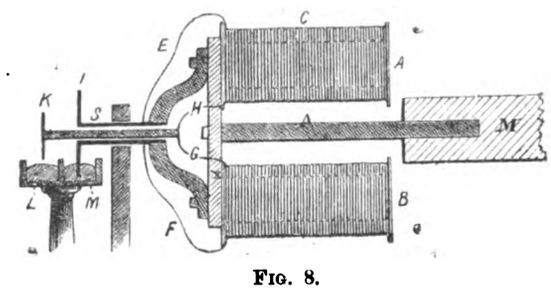

Fig. 8.

about 2in. in length, which, by means of a cross-piece of iron (the yoke, X), are connected together parallel to each other at such a distance that they shall be opposite the middle of each pole of the horseshoe magnet. Around each limb, C D, of the armature a long fine copper wire covered with silk, to insulate the coils from each other, is wound in several successive layers. The corresponding ends of each of these helices are connected together; one pair, E F, is soldered to the spindle, S, on which the armature rotates, and through it is connected with a circular copper disc, I, the edge of which dips into a cup of mercury, M, whilst

Digitized by Google

the other pair of wires, G H, is connected with a stout piece of copper which passes through the axis of the spindle, S, from which it is electrically insulated, and terminates in a slip of copper, K, placed nearly at right angles to the yoke, X, which connects the two limbs of the soft-iron armature. Beneath the slip of copper, L, is a second mercury-cup, N, which can be made to communicate with the cup M, either by a wire or by some other conductor of the current. The arms of the slip, L, alternately dip into the mercury and rise above it, and the points of contact are so arranged that the circuit (which when N and M are properly connected is complete so long as L is beneath the mercury) shall be broken at the time that the armature loses its magnetism."

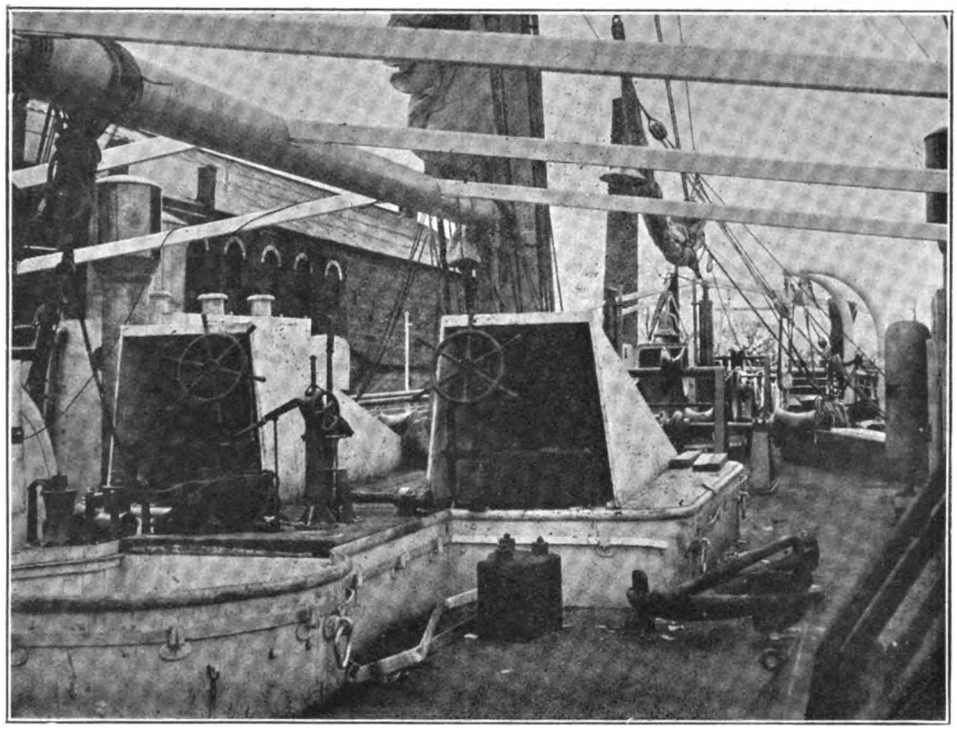
Numbers of these magneto machines were designed from the time of Faraday, 1831, until, say, about the year 1880; but as soon as electrical work entered into what may be termed the engineering stage they had to give place to a different type of machine, till now they are used to any extent only in electric bellwork.

DESCRIPTION OF GEAR FOR JAPANESE SUBMARINE CABLE STEAMER.

A few months ago the Japanese Government, as represented by their Glasgow consul (Mr. A. R. Brown), entrusted Messrs. Johnson and Phillips with the construction of a combined picking-up and paying-out gear, together with outfit and stores for their new submarine cable-laying vessel, of which the following is a description. The gear, as shown in the photographs which we reproduce, is very compact, and has been constructed principally of steel so as to combine strength with lightness, the weight all told being only about 21 tons. Although specified to pick up under a strain of 25 tons at 175lb. pressure, the gear on official trial showed itself equal to a much greater pressure compared with the gear by the same makers fitted on the "John Pender," "Great Northern," "Chiltern," "Electra," "Magneta," "Recorder," "Relay," "Cita de Milano," and many other steamers; it is equally powerful as the three first-named, and twice as powerful as the others, while at the same time it is infinitely more compact and lighter than any that have gone before.

The gear stands on a strong steel girder bed on the main deck, and the drums, etc., project through a hatch in the spar deck, and this is fitted with covers which form the driving platform for the machine. The gear has overhung drums, 6ft. 3in. diameter by 2ft. 6in. wide, internally geared and running loose on a fixed shaft carried on two steel frames, and is arranged for four speeds. The motive power consists of one vertical compound engine, having cylinders 12in. and 24in. diameter by 14in. stroke, capable of developing 265 h.p. without the use of the condenser, in conjunction with which it will, however, generally be used. The engine is fitted with link motion reversing gear, and also with automatic by-pass valve for admitting high-pressure steam to low-pressure cylinder for starting. The crankshaft is geared to the first motion shaft of the machine by means of double helical bevel gear. When it is desired to pay out without steam power, the only moving portion of the machine is the drum, which is readily controlled by the brake. To enable the drum to revolve independently of any other part of the gearing, provision had to be made for sliding the drum pinions out of gear, and as it was essential to keep the drums close up to the frames, these pinions have been arranged to draw through the frames. This has been effected in a very neat manner by the makers, two large holes being cut in the frame plates and a large pocket casting fitting into these carrying bearings each side of the frames, so that the pinions which gear into drums run between two bearings, the arms of the drum being set back to allow for this outer bearing. These pinions are put into and out of gear by means of a combination of hand-wheels, screws, and bell-crank levers. All wheels are arranged to draw out of gear when necessary, so that only the particular set required needs to be in gear. The brake straps are of steel plate fitted with elm blocks. The lower parts of the straps have large cast-iron eyes attached to them, and these are kept in position by means of a shaft 3½in. diameter, which passes through both frames. The braking power is applied by means of right and left hand screws working in nuts attached to the upper parts of the straps, the screws being actuated by means of hand-wheels from the starting platform, and when the straps grip the brake drum the pull is transmitted to the machine frames through the before-mentioned eyes and shaft, and thus to the deck of the vessel. A water service is provided for the brakes, the water being distributed by means of a small Worthington pump. Each drum is provided with two "knives" for fleeting the cable on the drums to suit either an inside or outside lead, as the case may be.

There are three sheaves at the bows, 51in. diameter by 11in. wide, the two outer ones being V section and the middle one U section. These sheaves are of steel, with



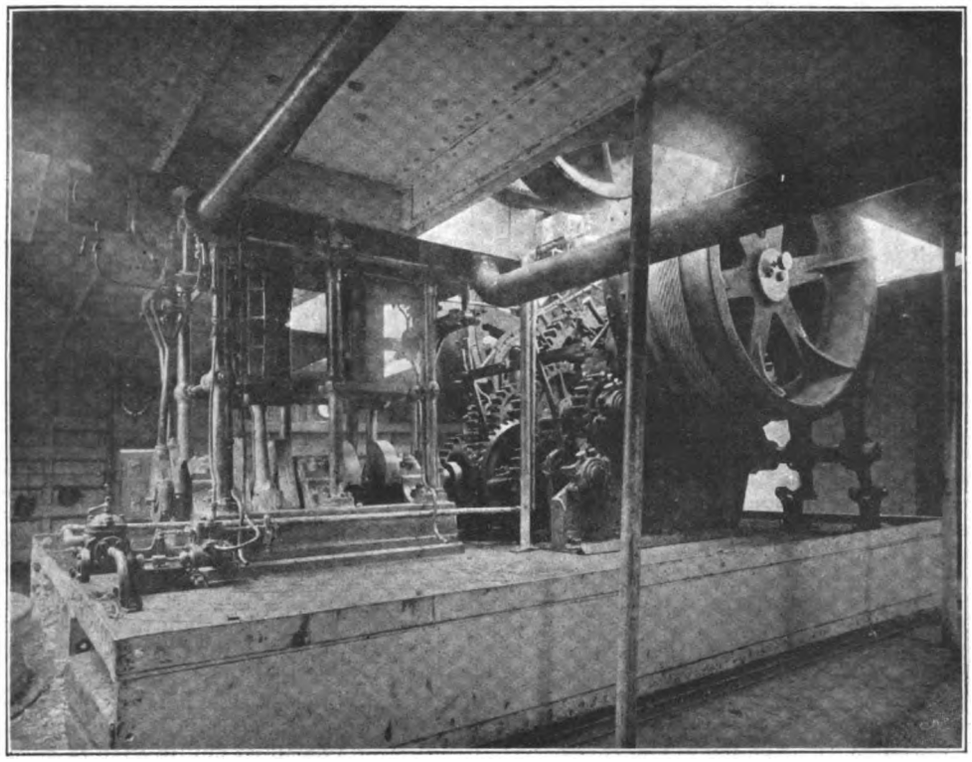
Cable Gear, by Messrs. Johnson and Phillips.

Digitized by Google

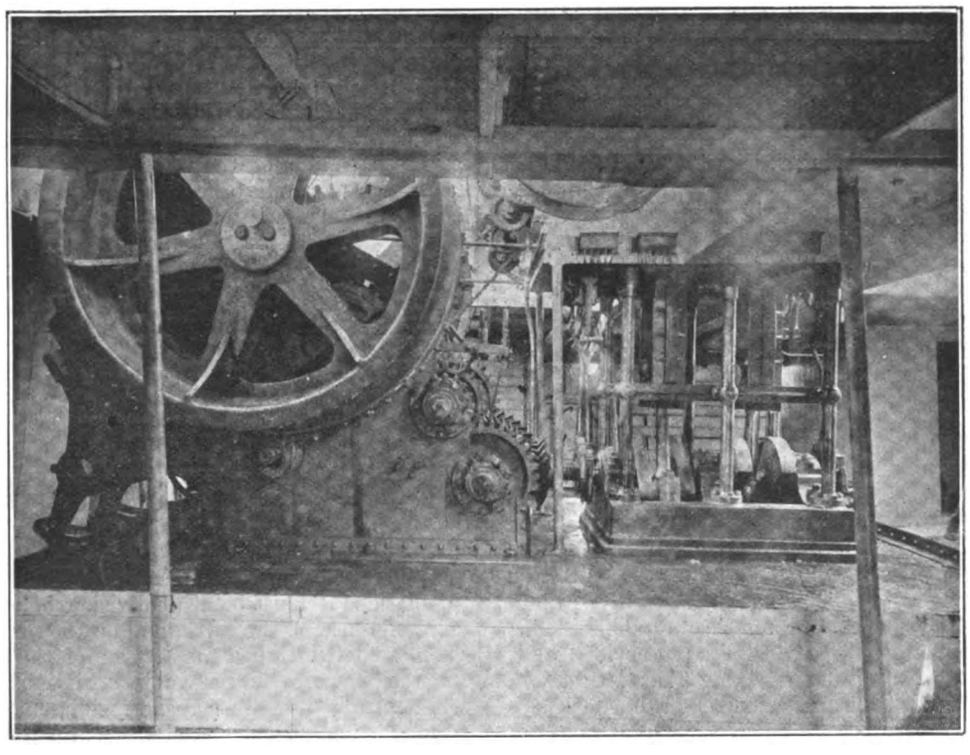
gunmetal bushes, and they are arranged to run loose on a steel shaft fixed in blocks carried on four steel girders, which are built into the ship for a distance of several feet, being connected to the beams and to the steel deck. Each sheave is provided with a cast-iron "whisker," or guard, at each side to prevent the cable from coming off. The two outer whiskers carry davits with a cross-bar for convenience in launching mushrooms, grapnels, etc. The side plating of the ship is carried out to meet these castings, thus giving the bows a very neat appearance.

The stern gear has but one sheave, which is 38½in. diameter by 11½in. wide, and is fitted with gunmetal liner to run loose on a shaft fixed on blocks carried by rolled girders. These girders are attached to the deck by means of special castings, which also serve to secure the necessary stopper hooks.

The cable machine is placed just aft of the foremast, and between it and the bow sheaves are placed the two dynamometers (one for each drum) for the purpose of registering the strains that come upon the cables or grapnel ropes. To effect this, a set of leads consisting of A frames and sheaves is placed at a certain distance on each side of the dynamometer, so that when a strain comes upon a cable or rope the moving part of the dynamometer is raised, the distance raised being in measure of the strain according to the weight of the moving part.



Cable Gear by Messrs. Johnson and Phillips.



Cable Gear by Messrs. Johnson and Phillips.

Digitized by Google

The dynamometers are of Messrs. Johnson and Phillips's approved design, consisting of cast-iron footstep with steel cylinders, on which a large cast-iron sleeve slides, and to this sleeve the sheave is attached, and also two side rods which carry a cross-head some distance above. To the cross-head is attached a piston-rod with piston, which works on the outside of the steel cylinder, which is filled with oil, and the piston being a loose fit this acts as a dash-pot to steady the movement. The top of the steel cylinder is, of course, fitted with a packed gland.

SUGGESTIONS FOR A DUODECIMAL SYSTEM OF NOTATION, WEIGHTS, AND MEASURES.

BY G. HALLIDAY.

[Some years ago the following article was sent us, but the time for its use seemed inopportune, though in a measure we agreed with the author's condemnation of the metric system. Incidentally Prof. Lodge, during one of the discussions at the last meeting of the British Association, uttered an emphatic protest against the adoption of the metric system; at any rate, his words conveyed that meaning to us. Mr. E. L. Garbett, many years ago, if our recollection serves us, put the arguments against the French decimalism system into a pamphlet. More recently the *Times* has inserted a series of articles and a number of letters on the subject, so that we think the time is ripe for a little elementary information for general readers—for those, in fact, who do not quite understand the different systems so often referred to by various writers.—ED. *E. E.*]

The younger race of engineers who deal with measurable quantities and working-men have for some considerable time held that the praise poured forth on the metric system, and consequently on our base of notation, is, to say the least of it, rather out of place. One cannot certainly say much against the advantages of man being endowed with 10 fingers, that he has exactly 10, not more or less; but one does not expect him to go into ecstasies over the matter and get on the stump and declare that he has 10 day after day with fearful iteration for all time: least of all does one expect that those who have the honour of being what are commonly known as mathematicians and scientific men should also begin to boast of their ability to count 10 and to glory in the genius they had displayed by selecting this number 10 as the base of all their calculations just because they happened to have 10 fingers. Under certain conditions this number could not very well be improved upon. For example, in a country where savages exist it might be found convenient for assisting one of them to understand what you mean by such a number as 15 to hold up both hands with the fingers spread out, lower them, and then hold up one hand spread out as before. Elsewhere, however, and especially where the people make some pretensions to learning, and more especially where a section of the people have considerable mathematical knowledge, we might expect something better than the "convenience-of-savages" argument given as a reason for the continuance of the base 10. Nor will it do to argue for its continuance because of its antiquity. This is no very special argument in its favour, for the Welsh count by fives and scores, and have done so for no mean length of time, and yet there exists no Englishman who does not think that they should give up their own system and adopt his—nor does he hesitate to enforce them to do so. Speaking mathematically, I do not think that anything which has not been established on a sound and mathematical basis deserves preserving: and I will now give my reasons for thinking that 10 does not deserve to be preserved as a base, and I shall show which other number would serve most conveniently as a base of notation, weights, and measures.

Our English unit of length is the distance between two scratches on two gold plugs sunk in and near the ends of a bronze bar. This distance is not connected with any physical measurement, for Parliament in quite an arbitrary way settled that this physically unconnected distance marked out on the bronze bar was in future to be considered by the English people as their unit of length. Should any injury be done the bar, by fire or otherwise, the machinery of Parliament would again have to be set agoing to enact that another distance, or, accidentally, the same distance, should after that time be recognised as the unit of length.

Neither has this unit the yard been happily chosen to facilitate calculations. Especially is this the case as regards its multiples; one of them being actually the number $5\frac{1}{2}$. In fact, they could not possibly be more crudely taken. They are quite systemless, and this is so much the case that English scientific men have entirely discarded the unit and adopted the metric system in its place. Indeed, were it not for the sub-division disadvantages of the metric system, engineers and others connected more closely with measurable quantities would have taken the advice of the great gauge engineer, Whitworth, and adopted it long ago. But it no way appeals to the practical man's innate sense of division. He likes to divide things into pairs or threes. And then, again, the decimal system is so cumbrous. Fancy our old familiar $\frac{1}{16}$th of an inch being measured by such uncouth figures as ·0625! Even Whitworth, with all his courage, must have had misgivings when recommending such a number to the select of practical Englishmen in place of the old, better, and familiar $\frac{1}{32}$. Sub-division under the metric system has not been a success, and Whitworth failed to establish it as a part of our engineering practice. He did all he could for it, however, for on the gauges which his firm supplied to other engineering firms he caused to be marked the decimal equivalents of the $\frac{1}{8}$ths and $\frac{1}{16}$ths, etc. No mechanic reads them, and although for purposes of calculation the English scientific man has adopted the metric system, the practical working-man sticks to the old foot with all its needful sub-divisions of inch and line, and in spite of all its multiple faults.

Of all working-men, the Englishman is, perhaps, the most sensible, the most practical, and when we examine the unit which the English sailor takes we find that for his purposes it could not be better. For facilitating calculation it is necessary that the sailor should have his unit in some way connected with the earth's circumference, and this he has just done, for his unit of length is the length of the arc on the equator subtending an angle of one minute at the centre of the earth. The yard does not pretend to be connected with the length of the circumference of the earth or with the length of the arc of any angle made with any radius, and so it does not specially appeal to the sailor for its adoption by him; and the metre, though closely connected with the circumference of the earth, and consequently with the division of the right angle, 90deg., is so helpless in the number and particular sub-divisions and multiples of the angle and of distances that it also does not specially appeal for its adoption. Neither system has appealed to him, and his practical reason has led him to reject both.

Some time ago an enterprising weekly science journal sent out circulars requesting information with respect to the different kinds of gauges and scales used in this country. Although it has not yet transpired what practical use they intend to make of the information so obtained, there is no doubt that when they place the matter into the hands of some practical man, as they are sure to do, he will recommend a unit of length which will satisfy the requirements of the sailor and the engineer, and connect it with a system of numbers made up on a base which will satisfy the most fastidious calculator. For the purposes of the sailor's calculations it must be a sub-division of the length of the circumference of the earth, and on the same system an arc of an angle which is a sub-division of the right angle. And for the purposes of the engineer it must be sub-divided and multiplied by a number which admits of the highest form of sub-division. And, lastly, for the purposes of the calculator, a new notation must be got out, and the base of that notation must be that number which is found for sub-division purposes most suitable to the engineer. For reference purposes it must also be a sub-division or multiple of a constant indestructible physical length.

Now, there are many things which would suit one of them best, but we must have one which, though it may not suit each best, will suit all very well; and the number so

Digitized by Google

chosen must commend itself to the mechanic in the very first place.

Now, the number which appears to be the greatest favourite with working-men for the purposes of sub-division is the number 12. The engineer has adopted it for the division of the foot into inches, and all the spaces which the compositor employs are also fractions of 12; the sub-division of the shilling is 12, and the zodiac has been divided into 12 equal parts. Ten only admits of division into halves and fifths, while 12 may be halved, and each half again halved, and it can be divided into three equal parts and each of these again halved. Indeed, of all our small convenient numbers, 12 lends itself best to the process of sub-division.

The adoption of the number 12 for the purposes of sub-division and multiplication of our units would necessitate the adoption of the number 12 instead of the number 10 as a base for our system of numbers; for we must be able to read off our answers by the mere placing of the decimal point just as we do when using the metric system.

The use of 12 as a base of our system of notation will be best explained by taking an example. Take the figures 59. Under our present system they mean nine units added to five times 10; but under the proposed new system, which has 12 for a base, the figures would mean nine units and five times 12, what we at present call 69, the number 5 having a value, in virtue of its position, greater, however, in the latter system than under the former. So, under the present system, the figures 8,972 have the meaning shown below:

Two	stands for 2 units	2×1	=	2
Seven	,, 7 tens	7×10	=	70
Nine	,, 9 hundreds	$9 \times 10 \times 10$	=	900
Eight	,, 8 thousands	$8 \times 10 \times 10 \times 10$	=	8,000
				8,972

But under the new system, with its higher base, 12, the figures would mean

Two	stands for 2 units	2×1	=	2
Seven	,, 7 twelves	7×12	=	7×12
Nine	,, 9 (twelves)^2	$9 \times 12 \times 12$	=	$9 \times 12 \times 12$
Eight	,, 8 (twelves)^3	$8 \times 12 \times 12 \times 12$	=	$8 \times 12 \times 12 \times 12$

or, $8 \times 12^3 + 9 \times 12^2 + 7 \times 12 + 2$.

And this is still to be represented by the figures 8,972. To do this some changes must be introduced into our manner of counting units. Under the present system, which has the number 10 for a base, we count up to the number 9 before we begin to represent the number with two or more characters, but under the new we would count up to 11 before we begin to represent numbers with two characters. Under the present system 10 is represented by 10, under the new 12 must be represented by 10, and 10 and 11, which at present are represented by double characters, will under the new system be represented by single characters.

Mr. E. Lonsley, instructor of mathematics in the Royal College of Science, Dublin, has suggested then 10 should be represented by an Old English 6 laid on its face, as shown (ϭ), and 11 by the same figure laid on its back, as shown (ϭ).

The numbers up to 12 will then be represented by the following characters:

1	2	3	4	5	6	7	8	9	ϭ	ϭ	10
one	two	three	four	five	six	seven	eight	nine	ten	eleven	twelve,

and higher than 12 and up to 24:

11	12	13	. . .	19	1ϭ	1ϭ	20
firsteen	secondteen	thirteen		nineteen	tenteen	eleventeen	twenty,

and from 132 to 144:

ϭ1	ϭ2	. . .	ϭ9	ϭϭ	ϭϭ	100
eleventy-one	eleventy-two		eleventy-nine	eleventy-ten	eleventy-eleven	hundred.

If we wish to do an addition sum by this system, we have only to remember that we have to carry we must divide by 12 instead of 10 as before. For example, take the following sum:

8,674
5,732
4,565
61,74ϭ

The answer being sixteen thousand seven hundred and forty-eleven.

Below stands a multiplication table made out to a base 12:

1	2	3	4	5	6	7	8	9	ϭ	ϭ	10
2	4	6	8	ϭ	10	12	14	16	18	1ϭ	20
3	6	9	10	13	16	19	20	23	26	29	30
4	8	10	14	18	20	24	28	30	34	38	40
5	ϭ	13	18	21	26	2ϭ	34	39	42	47	50
6	10	16	20	26	30	36	40	46	50	56	60
7	12	19	24	2ϭ	36	41	48	53	5ϭ	65	70
8	14	20	28	34	40	48	54	60	68	74	80
9	16	23	30	39	46	53	60	69	76	83	90
ϭ	18	26	34	42	50	5ϭ	68	76	84	92	ϭ0
ϭ	1ϭ	29	38	47	56	65	74	83	92	ϭ1	ϭ0
10	20	30	40	50	60	70	80	90	ϭ0	ϭ0	100

Sailors, as I said before, have chosen quite naturally the most scientific and rational unit of length, it being such a unit as simplifies their calculations of distances at sea. Their unit is the average length of the arc subtending an angle of a minute at the equator. If the division of angles by the English system were the best, then the mariner's nautical mile—the knot—is the very best practical unit of length; but the division of angles is not the best, for it is not connected with a decimal system of notation; and the French system is even worse, for it does not admit of the even measurement of such very common and important angles as 30deg., 60deg., 75deg., and 15deg.

A change of division of angles to the duodecimal scale will obviate both difficulties. A degree can be taken as one-twelfth of the right angle, a minute as one-twelfth of a degree, and the second as one-twelfth of the minute.

The arc subtending the second measured along the equator can be taken as the mariner's unit of length, which will be, if we take the circumference of the earth at the equator equal to the length of the meridian passing through Paris, just about equal to the old unit, the league, or more exactly, 227,871·6in.

The league, again, may be divided into duodecimal scale in the following way. In doing so, the names given to the lengths representing the sub-divisions may be taken to correspond to the names furlong, yard, foot, etc., or to the French system with such names as duo-decifoot, duo-kilofoot, etc. Taking the former, the table of lengths will stand as under:

TABLE OF LENGTHS.

One line		
Twelve	lines	= 1 inch.
,,	inches	= 1 foot.
,,	feet	= 1 yard.
,,	yards	= 1 pole.
,,	poles	= 1 furlong.
,,	furlongs	= 1 league, or 227,876·6in.

The foot which we might conveniently take as our principal and fundamental unit will, curiously enough, coincide with the foot in our present table of lengths—the length in inches according to the latest determination being 11·996293in.; and if it be remembered that the length of the equator is slightly longer than the meridian through Paris, the new foot may be taken for all practical purposes equal to the old, and therefore involve no very radical change in our present engineering practice.

Digitized by Google

Expressed under the new system of notation, our table of lengths will stand thus:

1ft. = 11·996293in.

1 line.
10 lines = 1in.
100 ,, = 10in. = 1ft.
1,000 ,, = 100in. = 10ft. = 1 yard.
10,000 ,, = 1,000in. = 100ft. = 10 yards = 1 pole.
100,000 ,, = 10,000in. = 1,000ft. = 100 yards = 10 poles = 1 furlong.
1,000,000 ,, = 100,000in. = 10,000ft. = 1,000 yards = 100 poles = 10 furlongs = 1 league.
1,000 leagues = quarter of earth's circumference.

For small areas the square inch will be most convenient, and for the measurement of land the square pole might be taken. For small volumes, and for calculating the weights of materials, the cubic inch will be found very convenient. The cubic foot, of course, will contain, under the new system of notation, 1,000 cubic inches.

The best unit of mass will be the quantity of matter which contains the same amount of matter as a cubic inch will contain of distilled water at the maximum density 4deg. C. This might be called a "mass," and the confusion at present existing by calling the units of mass "pressure" and "weight" would be obviated.

The table of measures of mass expressed in the same manner as the French and under the new system of notation would stand thus:

TABLE OF MEASURES OF MASS.

1 duo-milimass.
10 duo-milimasses = 1 duo-centimass.
100 ,, = 10 ,, = 1 duo-decimass.
1,000 ,, = 100 ,, = 10 ,, = 1 mass.
10 masses = 1 decamass.
100 ,, = 10 ,, = 1 hectomass.
1,000 ,, = 100 ,, = 10 ,, = 1 kilomass.
1,000 kilomasses = 1 quatreton.
1 mass weighs ·03612lb.
1 kilomass 62·425lb.
1 quatreton about 4 tons.

There is still another fundamental unit to be brought under the duodecimal system, and that is the unit of time. The unit of time to which all other units of time must be referred is the day, the day being the time taken by the earth to complete one revolution about its own axis. Lately, an attempt was made to get over the difficulty of dividing the day into two parts of 12 hours each, and distinguishing the one set of hours from the other set by affixing the letters a.m. and p.m. The suggestion was to count 24 hours to the day, calling 1 p.m. 13 o'clock and 9 p.m. 21 o'clock. The suggestion has not been received with much favour. If the unit of time is to be connected with the duodecimal system it will be best to divide the day into 12 parts, and make each division equal to two hours. In this way the measurement of time might be arranged as under:

TABLE OF TIME.

1 second
100 seconds = 1 minute
10,000 ,, = 100 minutes = 1 hour
100,000 ,, = 1,000 ,, = 10 hours = 1 day.

The present second is one 86,400th part of the day, and the new second would be one 248,832nd part of the day.

As the price of things should also be found by the mere placing of the decimal point, it will be necessary to make a table of money. The following looks fairly well:

TABLE OF MONEY.

1 penny.
12 pence = 1 shilling.
12 shillings = 1 mark.
12 marks = 1 note.

Or thus:

1 penny.
10 pence = 1 shilling.
100 ,, = 10 shillings = 1 mark.
1,000 ,, = 100 ,, = 10 marks = 1 note.

The units in the duodecimal system which would answer to the units in the centigrade gramme system will be the inch, mass, and second.

The advantages of such a system are not quite apparent at first sight. They, however, may be shown by working out sums by both systems and comparing the amount of work done in both cases. There is another advantage which is not apparent in calculations, and which can be only felt by the engineer and draughtsman—that is, the advantage gained by having a better and wider system of subdivision combined with a decimal system. However, the advantages of the system, as far as calculation is concerned, are sufficiently shown by the two like sums which are worked below. It will be observed that under the new system four different operations are found necessary, and under the present 10 must be made.

Example: A block 9ft. × 4in. × 7ft. and specific gravity = 7 at 3d. per mass; find its value:

9
4
—
3·0
7
—
19000 cubic inches
7
—
103000 masses
3
—
309·000 notes

In the present style this example would stand thus:

A block 9ft. × 4in. × 7ft. and specific gravity = 7 at 3d. per pound; find its value:

9
4
—
3·0
7
—
21, cubic feet.
7
—
147
62·5
—
735
294
882
—
9,187·5lb.
3
—
12)27,562·5d.
—
2,0)229,6·8s.
—
£114. 16s. 10d.

The above are only suggestions, and I think they at least sufficiently show that no very radical change is necessary for the adoption of such a system of notation, weights, and measures as far as the engineer is concerned.

Niagara Falls.—The *Western Electrician* states that when the third generator now being erected in the central power station of the Niagara Falls Power Company is completed, the total power product there will be 15,000 h.p. It is, however, stated that as many as seven more dynamos have been contemplated, but nothing is at present decided as to their erection.

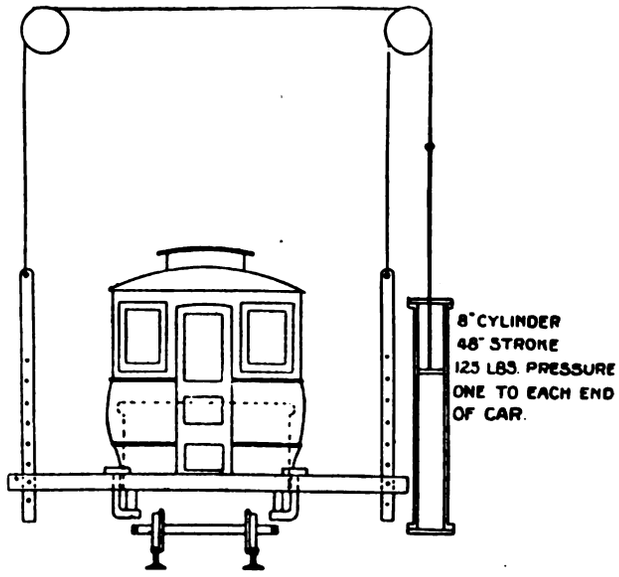
HYDRAULIC HOIST FOR CAR BODIES.

Of the many handy schemes for hoisting car bodies that we have seen and which have been described in the columns of the *Street Railway Review*, one of the best is that put in by Thomas Elliott, chief engineer of the Atlanta Consolidated. The plan of the arrangement is shown in the accompanying diagram. It is a hydraulic hoist with two 8in. cylinders 48in. long, standing on end, and bolted to the floor. Cables



Hydraulic Hoist at Atlanta.

run from the pistons over pulleys overhead. Water at 125lb. from the boiler feed pump is employed for operating the hoist as only a small amount is used.

INSTITUTION OF ELECTRICAL ENGINEERS, April 16.

SIR HENRY MANCE in the chair.

At last night's meeting of the Institution the following candidates were balloted for:

Associates.—Stanley J. Goddard, the National Telephone Company, Oxford-court, Cannon street, London; William Johnson, the National Telephone Company, Sheffield; Walter Victor Morten, the National Telephone Company. Oxford-court, Cannon-street, London; Robert Ellis Shawcross, 66, Lexham-gardens, W.; Arnold Turner, Denton, near Manchester; Ernest Anthony Max Winter, 53, Charterhouse-street, E.C.

Students.—Edward Nugent Bankes, Arc Works, Chelmsford; Sidney John Clay, 11, Scarborough-road, Finsbury Park, N.; Benjamin Shuttleworth Hornby, 2, Hilda-road, Mostyn-road, Brixton; Charles H. Rosoman, Holder's-hill, Hendon, N.W.; Ralph Rushton, jun., Bernard Sankey, Percy Cunliffe Simpson, and William George Stuart, Faraday House, Charing Cross-road, W.C.; Frank Triste Wordley, 235, Burrage-road, Plumstead.

After the usual business, the discussion on Mr. Dane Sinclair's paper, "Telephone Exchanges and their Working," was proceeded with.

Mr. Kingsbury said, before he discussed the paper, he would like to call attention to the fact that Mr. Sinclair brought forward two rather important questions with a view of improving the local service, and, to some extent, to reduce its cost. Those were two points on which it was impossible to hold other than one opinion, and they must all be in accord with Mr. Sinclair in his aims, but it was open to some of them to feel that there were other ways of obtaining those results, and they might even go so far as to remark that in his methods he did not obtain the results he aimed at. In reference to the call-wire system, Mr. Kingsbury quoted from a speech delivered in that room by Sir Frederick Bramwell in 1883, and said that now that no novelty existed in regard to the system they had to consider that some experience had been gained between 1883 and 1896, and it did happen that the system was in process of being discarded. In October, 1883, Mr. Lockwood attended the convention at St. Louis when the call or Law system was dealt with. The remarks he then made induced the superintendent to look up the English records, and he found that the Law system stood very well on the list of those towns that had a large number of telephone services. He also found a statement showing the number of subscribers in the four large Scotch towns during the last five years. Dundee and Aberdeen had been using the Law system during that period. Edinburgh had been using the indicator system, and Glasgow had been using both systems. The subscribers in Aberdeen had increased 82 per cent.; in Dundee they had increased 57 per cent.; and in Edinburgh they had increased 140 per cent. That was not enough for them to assume that it was in any way a conclusive comparison, because four towns were hardly a sufficient number to make an average. He only put that forward as a suggestion whether the Law system was or was not a progressive system. With regard to the extent to which subscribers made use of their telephones on the various systems, he found that Glasgow had six and a half calls per day per subscriber, compared with Liverpool; that was just one-half. If the Law system facilitated subscribers, and was of use to them, they must consider how much they used it. All the towns using the Law system were somewhat below the towns of similar size in the United Kingdom. Mr. Sinclair had told them that the subscribers liked the call wire: that 95 per cent. of them in Glasgow preferred the call wire to the indicator system previously in use. The weak point about that statement was that they had not all the material before them on which to form a judgment. What they wanted to know was, what was the indicator system previously in use? He attached very much more importance to Mr. Sinclair's statement that, having studied the matter as an engineer, he was of opinion that the Law system should be introduced. With regard to flat boards they were originally introduced in the Law system before the introduction of the multiple switchboard. Mr. Kingsbury dealt at some length with the advantages of the upright boards as compared with the flat boards, and said the real controlling factor was not electricity at all, it was simple anatomy. A man could describe a complete circle with his arm vertically, but horizontally he could only describe a semicircle and, therefore, a multiple switchboard on the upright had double the capacity of a switchboard on the flat. The comparisons as to cost in the paper were made entirely on what might be called the old times. Each operator in those days had 50 subscribers: now they had boards made for 450 subscribers worked by three operators, and boards of 360 were quite common, giving 120 subscribers to one operator. The whole question between the upright board and the flat was simply a question of saving working cost or saving working expenses.

Mr. Binswanger said he had had his doubts as to how the public would take to the call system; but from experience he could say that he could endorse everything Mr. Sinclair had said upon this subject, and that in spite of the remarks of Mr. Kingsbury. They had occasion in Manchester to use both the call system and the annunciator system side by side, and his own experience was that the call system was preferred. They felt they were in more direct communication with the exchange, and also with the subscribers. They certainly got a much quicker service. It was a question whether they could not put more work on the subscribers and thereby make the exchanges more automatic. He was told an automatic system was in operation in several places in America, having subscribers up to 200. It would be extremely interesting and useful if they could hear from Mr. Sinclair what he thought of automatic systems. If such a system could be devised, which was both simple and reliable, it would be extremely useful in small exchanges.

Mr. Preece complimented Mr. Sinclair on his paper. It was the first time a representative of the National Telephone Company had come forward to read a paper before that Institution and tell them what the company was doing. He (Mr. Preece) had in the past spoken very strongly upon the management of the National Telephone Company. It had been execrable. But a change had now come over the spirit of their dream, and the company was not only repairing the damage of the past, but was showing an amount of enterprise and energy which would put the telephone industry in this country into a position which would enable it to compare favourably with any other country in the world, America not excepted. He had seen much of telephone working in America, Norway, Sweden, Germany, and other countries, and he found that the National Telephone Company was taking the cream of what had been done elsewhere, and we in England were to reap the benefit. Mr. Preece added that he disagreed with Mr. Sinclair on the subject of multiple switchboards, and thought that the day of the multiple board was almost over, since as the exchanges grew the expenses of them became too great. When the number of subscribers reached 5,000 the difficulties were enormous. He could not speak on trunk working at present, as the Post Office had only just taken over the lines, but he hoped that by the commencement of the next session of the Institution they would have in England the finest trunk line system in the world, and he also hoped that the next session would be opened by a paper on the subject by Mr. Gavey, who would describe it. As to the call system, or Law system, Mr. Preece objected to i because it was actually unnecessary. In the Post Office their cal was automatic, and there was only one objection to that—namely, that a continuous current was required to work it, and that was no real objection to those who had tried it. He did not like flat boards for practical reasons—namely, the difficulty of the engineer removing faults while the operators were at work. In the vertical boad that could be done without the operator knowing anything about it. Another point was that, though the operators might be perfect and the apparatus perfect, it was wanted to have subscribers equally clever to get the best results. Without mutual forbearance and assistance from the public they would never get satisfactory telephone working in this country. There was a great deal of difference in this respect between the way the telephone was worked in London and Berlin. In the latter city the subscriber did much of the work. He gave the number, was put through to his friend, and did the calling, and all the rest.

(To be continued.)

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

THAT WORKMAN AGAIN.

A "workman," says the highest authority, "is worthy of his hire." Everybody is ready to agree to this, but differences of opinion arise in the definition of "workman." The real article is to be honoured and respected; the makeshift, make-believe merits neither honour nor respect, but rather to be reprobated. It is not with the real workman we have again to deal, but with the makeshift. Carelessness upon a railway is almost certain to lead to an accident; similarly, carelessness in electric light fittings may lead to the destruction of property and danger to life. Even if the end of such carelessness be not disastrous in these ways, the probability is that it must lead to an almost continuous loss of current, and hence of money. Under the best circumstances, bad workmanship means greater than normal leakage, and this leakage has to be paid for by the consumer or the shareholder. A diatribe upon electrical fittings might well be divided into three parts—one directed against the employer who acts as if he believes he can get the best at any low cost; and one against the contractor whose performances do not come up to his promises. The latter winks the other eye; he has to make a profit somehow—for "he must live," you know. We, however, are not concerned with his living in any particular capacity, and if he is not straight as a contractor, the sooner he finds a living in some other capacity the better for all concerned. According to present information, we are inclined to the opinion that the worst features of electrical work are neither due to the parsimony of the employer nor the fraud of the contractor, but to the actions of the third party against whom the diatribe may be directed. This third party is the self-called intelligent workman—in reality, a make-believe, a dishonest, scamping rascal. We must again guard ourselves against the misinterpretation of our language. It is not directed against the real Simon Pure, only against the makeshift. The latter puts us in mind of the critics who play the fool before all the world in their weekly remarks upon contemporary technical literature. The makeshift in all trades arrogates to himself infallibility. He is the Alpha and the Omega, the embodiment of the laws of the Medes and Persians, the one and the only Jones. The real workman may be said to be only individually one of the vertebræ and collectively the backbone of the universe. To guard against the electrical make-believe workman the fire offices have to issue stringent rules, and to employ inspectors who examine the work carried out. What a tale these inspectors could tell, which if told, however, would do more harm than good. In another column we give sketches from actual work condemned and taken out of houses in the West-end of London. Our examination of the actual material brings us to the—we think—only possible conclusion, that neither employer nor contractor can be blamed, but only the makeshift workman. As a matter of fact the contractor must have been a considerable money loser, because the work had

Digitized by Google

to be done again to the satisfaction of the inspector. How much of this kind of work is hidden it is difficult to imagine. It is quite certain that the supervision of master, foreman, and inspector cannot be constant, and that at the best the examination by the latter cannot be certain of detecting every fault deliberately made by makeshift workmen. A man either knows or does not know how to make a joint. If he does not know, he should not undertake the work; if he does know, and makes a bad joint, he must do it deliberately, and all the adjectives in the English or any other language are insufficient to justly condemn his work. He knows the danger awaiting property and life, and yet he wilfully puts both into jeopardy. Let the men who seem to support this kind of thing find an excuse if they can; we own to having failed to find any. The case would be different if no harm could come of such work, but we all know that the multiplication of bad work increases many risks which ought to be avoided. Since the samples of English work we have commented on were brought to us we notice an address by Mr. C. C. Haskins to students at Chicago, given in our American contemporary, the *Electrical Journal*. Mr. Haskins directs attention to good and bad wiring, and, summing up his conclusions in favour of an exceedingly high standard of work, among others, gives this reason: "Because in electric work the best is none too good," and states that his motto has always been, "Fix it so it cannot, and it will not." The worst feature in these cases is that, though the work is often done through sheer carelessness or incompetence, the faulty portion happens to come in a position exceptionally dangerous. Hence condemnation should be constant and emphatic.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE INSTITUTION BALANCE-SHEET.

SIR,—I feel sure there are many who thank you for the outspoken comments on this subject, for, whatever Mr. Raworth may say, you have hit the nail on the head. It appears to me that the position of affairs is somewhat as follows:

Cause.—In an interview published by one of your contemporaries* in August last year, Sir David Salomons was straightforward—I use this word because there has been a great deal of molly-coddling of the Brush Company in the matter—enough to make statements about certain apparatus at the Bankside station. This must have wounded Mr. Raworth's feelings greatly, especially the references to the (40 yards sprint race) switch pillars. Those who have spoken to the attendants at the Bankside station will know what I mean.

Effect.—The first effect noticeable was the dead set made against Sir David Salomons being elected president of the Institution, and I am convinced that the nucleus of this action was in the quarter I have indicated. You yourself have pointed out effect number two, and commented upon it.

To conclude, I should like to know if our Institution is going to be ruled (the American word "bossed" more nearly expresses it) by a few Brush Company's officials and their worshipping admirers. If not, then the sooner Mr. Raworth confines his speeches at the Institution to technical matters, the better it will be for everybody.—Yours, etc.,

ANTI-SHOUTER.

* *Lightning*. August 15, 1895.

THE SNOWDON RAILWAY ACCIDENT.

SIR,—Although Mr. Lea in his letter anent the above, published in your last issue, disclaimed any serious attempt to theorise, yet his remarks involve one or two points which need correcting, especially in view of the evidence given at the inquest.

The accident was undoubtedly due to the track having settled, owing to subsidence of the soil, which is notoriously subject at this point to the influence of weather. No blame whatever ought to be attached to the engine or to the rack.

As for the question of electric motorcars being safer than, and generally superior to, steam locomotives, this may or may not be the case according to the respective gross weights in regard to such a circumstance as the runaway on Snowdon.

Undoubtedly electric motorcars would have involved less weight than the use of steam locomotives, but even then the train load might have been enough to depress the rails at this spot and so have caused the whole train to run off instead of the locomotive alone.—Yours, etc.,

A.M.I.C.E.

WHAT, WHEN, AND WHERE.

Institution of Civil Engineers.

April 17, 8 p.m.—At the Institution, Great George-street, Westminster. Students' meeting. "Recent Developments in Lighthouse Engineering," by N. G. Gedye (student).

April 21, 8 p.m.—At the Institution. Ordinary meeting. Papers to be discussed: "The Thirlmere Works for the Water Supply of Manchester," by C. H. Hill (member), and "The Vyrnwy Works for the Water Supply of Liverpool," by G. F. Deacon (member).

April 23, 2.30 p.m. Students' visit to the Linde British Refrigeration Company's works at Lower Shadwell. Train leaves Fenchurch street Station for Shadwell at 2.10 p.m.

April 23, 8.30 p.m.—Indian section. "The Deserted City of Vijianagar," by Captain Charles Rolleston.

WIRING WORK.

A good deal has been said and written lately about the wiring question. The unfortunate fire insurance inspector has been hauled over the coals and ridiculed by several would-be witty individuals, and it has been stated that the time will soon come when electric light installations will be treated by the fire offices in the same manner as gasfitters' work. How much of the feeling against the fire office inspectors is due to the fact that the objected work does not fall in with the requirements of the fire offices is hard to ascertain. The inspectors are, with few exceptions, reasonable men, and must not be always blamed because certain bad work has to be condemned. Some samples cut out of some London installations have recently been submitted to us, from which the following illustrations have

Digitized by Google

been made; they show to what extent bad work is often hidden away before the inspection takes place. The chief fault is in the joints, which are badly made, badly soldered, and badly insulated. The uncovered joint in Fig. 1 shows the careless way in which the ends of a stranded conductor were left projecting, and hence injuring the insulation. The other conductor leading from the joint broke when handled, as the wire had been nicked by the pliers. No single joint showed any care in laying up the wire, and the majority of the joints had just received a wipe from a soldering iron.

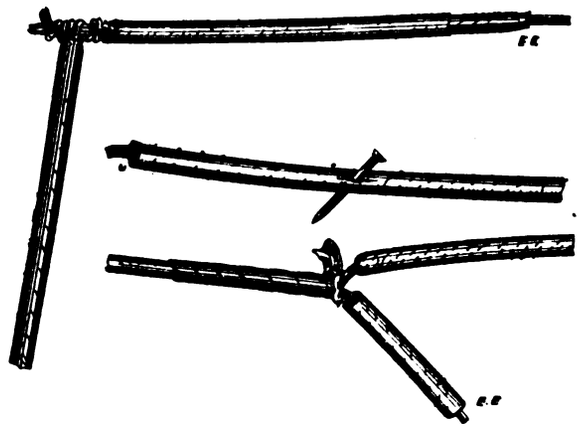

FIG. 1.

The solder under adhered to the outside, and had not sweated through to the centre of the joint. The insulation of these joints was not defective on account of insulating material, but due to bad workmanship. As will be seen from the illustration, the other joints and the body of the joints were well covered, but the ends were left practically open. Nails were largely used in fixing on the covers of the casing, and several wires were found pierced as shown. In this insulation the fuses were often situated under the floors.

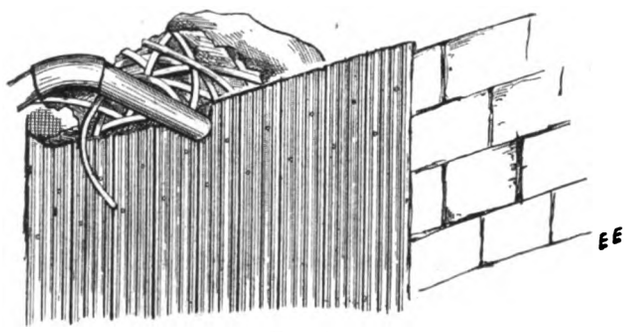

FIG. 2.

Fig. 2 is illustrative of wires bunched under a concrete floor, and in close proximity to iron girders and gas-pipes. As will be seen, the work would look tidy till the upper cover is taken off. Fig. 3 shows the method of tubing a wire through a road without any mechanical protection.

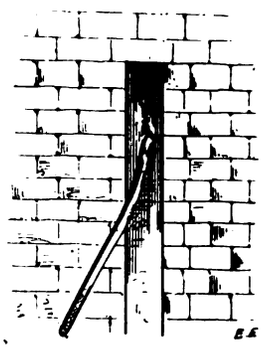

FIG. 3.

When such work as the above is put in with the knowledge that there will in all probability be an inspection, what may be expected when the contractor's word is taken as to the class of work? The adoption of a conduit system would to a great extent extinguish the jerry wireman, for the conductors, if properly installed, could be easily withdrawn for inspection; but with the use of wood casing it is to be feared that there are numbers of joints and faults similar to the above that will never see light, unless it be artificial light, inasmuch as they may sooner or later be the cause of fires.

A CENTRAL-STATION PROBLEM.*

BY C. R. VAN TRUMP.

An axiom that applies particularly to central-station operation is that what is good engineering for one case may be very doubtful in another. Probably we may never be so fortunate as to outlive all the errors of commission or omission which are to be met with each day in central-station practice, and the greatest errors are sometimes justified by the best practice of the day. Indeed, there is no type of apparatus and no method of operation which may be said to fulfil all the requirements. For instance, the central station of which the writer is in charge, and with which this paper deals, stands at or near the centre of distribution of a low-tension, three-wire system which forms three-fourths of the total output, about 600 kilowatts. Being one of the earlier plants, it is supplied with high-speed, non-condensing apparatus, and the haulage of coal amounts to 10 per cent. of the cost of the fuel on tracks; and yet the economy has not been very apparent in favour of moving the generating plant a distance of less than 2,000ft., in order to get water for condensation and fuel on a railway siding alongside fire-room, even with the use of modern steam apparatus. Although this would not seem self-evident, yet, when we consider that though we might hope to save about 40 per cent. in fuel, this item is less than 50 per cent. of the cost of current, and only 30 per cent. in our station, as we consider that our produce is electric service, not electric current. We would only gain 40 per cent. of 30 per cent., or about 12 per cent. saving, while the outlay would be about 5 or 6 per cent. of the cost of the current in additional interest, renewals, etc., and the electrical loss would be nearly as much more, leaving a small margin which would hardly pay. Of course, the case would be altered if an entirely new plant were considered.

But another method of getting far better results has been adopted which may prove of interest or practical value to other stations. It is often the case, especially in manufacturing districts, that large amounts of power are used with very poor economy; in fact, enormous wastes are not uncommon, especially in the case of water powers which are used in the daytime and at night are allowed to waste over the dam breast. The plan adopted by the writer has been to contract for this waste power, put in apparatus in the mills of the concern, and transmit all that could be spared to the centre of distribution, the power being bought on a meter basis and distributing on the present system. The mill-owners receive a revenue from this waste which amply pays them; the central station receives the power at lower cost than the ideal plant would produce it, and at very low outlay.

This central station carries a load on a three-wire direct-current system of about 600 kilowatts, covering a territory three-fourths of a mile radius from the station, and a single-phase alternating 125-cycle system load of 130 kilowatts at 1,200 volts, covering a territory outside of the direct-current system of 3½ miles radius, including suburban districts for incandescent work; and finally a constant-current arc load of 150 lights. In the question of economy, the high-tension plants were of first importance, as greater economy was possible with the direct-current apparatus. A sub-station with better economy was deemed inexpedient for these systems alone, as this would divide up the plant to no advantage in operating expense.

A proposition was made to a large cotton mill and dyeing concern near the town to sell current to the central station. The mechanical head of this concern, who, although not figuring as blasé in the engineering world, is nevertheless one of the best posted and deepest thinkers the profession can boast. He considered our proposition with great care. Their conditions were favourable, for besides a large water

* From the *Electrical World*

Digitized by Google

power, much in excess of their demands after the hours of operation during the day, they use a large amount of steam for heating purposes at 30lb. pressure. They had engines and boilers in reserve which they operated at 110lb. pressure, and it is very easy to see under such conditions that a simple engine operated at 110lb could be exhausting into the low-pressure mains at 30lb. back pressure, with the excess cost of steam at 110lb. over 30lb., or at less cost than the ideal station with the latest and largest equipment could possibly produce the power. This is apparent since 1lb. of coal is capable of giving about 11,500 B.T.U. to the water in a good steam-boiler, and at 30lb. pressure 1,165 B.T.U. per pound are in the steam, and only 22 more, or 1,187 B T.U. per pound, are needed to produce 110lb. steam pressure, while 1,146, or 19 less, are still in the steam at atmospheric pressure exhausted from a non-condensing engine Therefore, if in steam at 30lb pressure 22 B.T.U. are added per pound of steam, 1lb. of coal would raise 520lb. of steam from 30lb. to 110lb., or produce from 10 h p. to 15 h.p. on 1lb. of coal.

The plans were to meet the following conditions: Their water power was ample to supply 180 kilowatts, and in the daytime the steam power available under 30lb. pressure (their demand for steam being otherwise supplied by a low-pressure bank of boilers) was equal to this. The alternate-current load at dark became 150 kilowatts and dropped off at midnight to 75 kilowatts, supplying principally an incandescent municipal service. All the alternate-current apparatus was built for 125 cycles; the distance from the station to the mills was 12,600ft.; the attendants could not be relied upon for constant attention, although the speed curve showed close regulation of the power. Electrical power was also a necessary feature, both for the station and the mills. No spare electrical apparatus was to be provided, which necessitated keeping the old plant intact. The day load was exclusively direct low-tension current work.

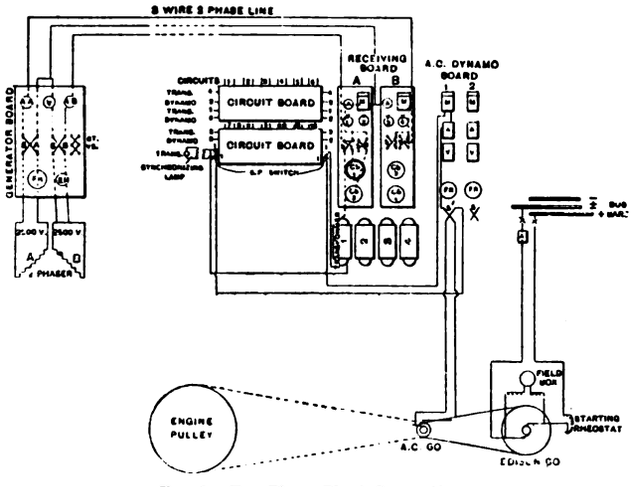

FIG. 1.—Two-Phase Plant Connections.

The plant installed (Fig. 1) to meet these conditions was as follows: A Stanley-Kelly two-phase machine of 180-kilowatt capacity, and 125 cycles, was belted direct to a jack-shaft with clutches so that it could be driven from either water-wheel or one or two engines. The line consisted of 12,600ft. of three No. 00 B. & S. weather-proof conductors (providing for future increase), with square yellow pine poles, 5ft. cross-arms and triple petticoat glass insulators, built to carry the current to the receiving board. Four special step-down transformers, 2,500 to 1,200 volts, were put on each side of the system; one side of the primary of each transformer was connected through the commutating switch, with a kicking coil to prevent short-circuiting, and with 15 terminals on the primary coil of the transformer; thus, with the switch on the first point, with 2,500 volts on the primary, 1,175 volts were available on the secondary of the transformers, while on the last point, with 2,500 volts on the primary, 1,325 volts were available. Ten volts between each point of the commutating switch admitted of varying the pressure on either of the four transformers without a loss or leakage through additional primary coils. The secondaries of the transformers were connected, as indicated, to transformers Nos. 1, 2, 3, and 4, to points Nos. 1, 2, 3, and 4 on each side of the old circuit board, these boards being cross-connected by means of plugs and double throw switches, carrying 12 circuits, so that any circuit could be thrown on either of two of the transformers connected to one of the boards, one on each side of the system, and the load thus perfectly balanced if desired.

Two of the single-phase machines were each placed in line with two 60-kilowatt direct-current Edison generators, driven from a single-expansion engine, so that the belts could be removed from the Edison dynamos and the alternators belted direct to the engine in case they were needed, or the alternate-current 60's could be run as synchronous motors driving the Edison 60's in the following manner: a rheostat was placed in the armature circuit of the direct-current dynamo so that it could be started as a motor; short belts were provided to connect the Edison machines with the alternators, and at the board switches were arranged so that either alternators could be thrown into multiple with one of the transformers on each phase, as shown in Fig. 1, for No. 1 alternator and No. 1 transformer.

The Edison dynamos are started as motors, bringing the

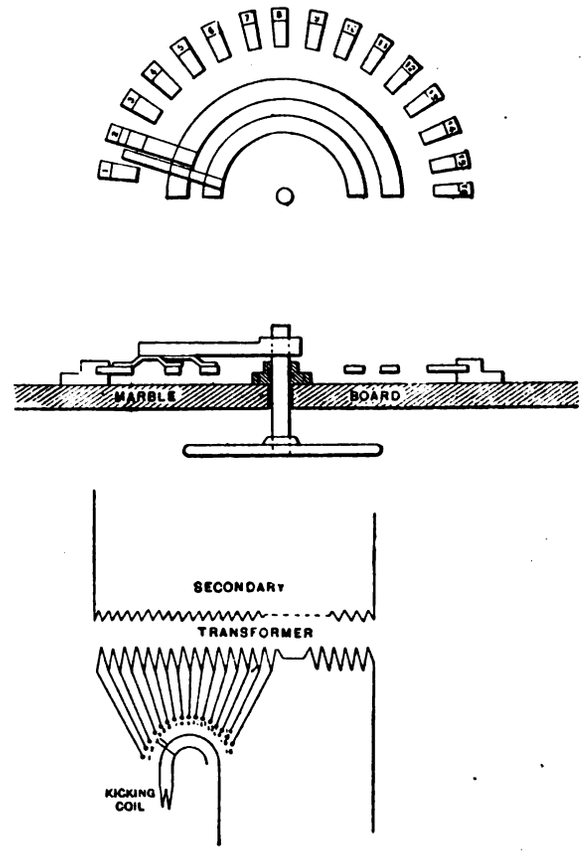

FIG. 2.—Regulator and Connections.

alternate-current 60's up to speed; a small converter and pilot lamp are connected across one of the single-pole switches for synchronising. By this arrangement the alternators are brought up to speed by the Edison machines running as motors; the resistance in the armature circuit is thrown out, and the speed varied by the field box of the Edison machines, the voltage of the alternators being varied by the field rheostat until it is equal to that of the transformers, one side of the alternator being connected to the transformer. The pilot lamp flashes as the machine goes in and out of synchronism, and when the speed is adjusted until synchronism is nearly reached, the pilot lamp goes out; the remaining switch connecting the alternator in multiple with the secondary of the transformer is then thrown, the field box of the direct-current machines is thrown out, and the load is taken by the latter on the three-wire system, the generators driving them as synchronous motors. This operation is performed every day without difficulty, the Edison machines after being thrown taking the load easily and smoothly. No induction losses occur on the lines; in fact, as the field excitation of the alternators is increased the machines kick back on the line

Digitized by Google

exactly like a condenser in circuit, counteracting any inductive effect of the line.

By this means, after the alternating-current load drops off at midnight, the synchronous motors driving the 60-kilowatt direct-current machines on the three-wire system are thrown in and carry the load, from 75 kilowatts on circuit board, to which it drops at midnight, up to 175 kilowatts, the steam plant then being shut down.

The plant has been in operation for the past four months with excellent results except a scarcity of water from the excessive drought, the water having until lately run lower than for many years. The only difficulty in operating is during the time the mill machinery and dynamos are both on the waterwheel, which necessitates extreme care in avoiding rapid fluctuations of load. The load is thrown on very slowly and taken off with the same care, as a rapid drop in load on the dynamos tends to make the waterwheel race with its sluggish governor.

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

BY DR. ARMSTRONG, F.R.S.

"All the facts show us that that power commonly called chemical affinity can be communicated to a distance through the metals and certain forms of carbon; that the electric current is only another form of the forces of chemical affinity; that its power is in proportion to the chemical affinities producing it; that when it is deficient in force it may be helped by calling in chemical aid, the want in the former being made up by an equivalent of the latter; that, in other words, *the forces termed chemical affinity and electricity are one and the same.*"—Faraday's "Experimental Researches in Electricity," 1834, Series VIII., § 918.

Foremost among the problems to which during recent years attention has been devoted is that of the nature of chemical change. Whilst English workers especially have made most important contributions to our knowledge of the conditions under which change will occur, foreign workers have been most active and successful in developing mathematical methods of treating the subject. Indeed, the statement recently made in a prominent chemical journal that "it has certainly become impossible to read chemical theory without a working knowledge of the calculus" is a striking comment on the alterations in the conditions under which the chemist will work in the future, which must serve to remind us how very different a preparation students must now undergo if they desire to thoroughly master the theories of our science.

The subject first came under consideration in this society just 10 years ago. In the discussion on Mr. Brereton Baker's paper on combustion in dried gases (compare *Proceedings*, 1885, 37), I ventured to insist that the evidence that action did not take place between two substances was so strong that chemists would ere long be forced to form a definite conception of the nature of chemical action and of the conditions under which chemical action could take place; and I then pointed that physicists were in advance of chemists, drawing attention to Ayrton and Perry's paper on the contact theory of voltaic action, in which it is directly stated that Ohm's well-known law is equally applicable to electrical and chemical changes.†

On the occasion in question I defined chemical action as *reversed electrolysis*, and explicitly stated that in any case in which chemical action is to take place it is essential that the system operated on shall contain a material of the nature of an electrolyte. The expression "chemical action" was used as including all cases of exothermic change, cases of endothermic change being obviously comparable with direct electrolyses, as in all such cases energy from without must be impressed on the system.

Later in the year, at the British Association meeting at Aberdeen, in my address to the chemical section, I discussed the matter more fully, and then stated in so many words that the conditions which obtain in any voltaic element are those which must be fulfilled in every case of chemical action. I carefully pointed out, however, that there was nothing new in this, and to justify my assertion drew attention to various passages in Faraday's "Experimental Researches in Electricity" in which such a doctrine is laid down in the clearest possible terms. Let me here again say that nothing is to me more surprising than the continued disregard of Faraday's teaching on this subject. We know that in regard to purely electrical questions, even in this country, it was not until Clerk Maxwell came forward as his interpreter that attention became riveted upon his conceptions; and abroad, even Clerk Maxwell was disregarded until Hertz's experimental demonstration ensured that respect being paid to his pleadings which they were so long denied. Faraday's views regarding chemical action have never yet received proper notice, although the language in which they are expressed is so simple and direct that they cannot be misunderstood, and their completeness is surprising.

But one conception has been added to Faraday's teaching—that of "electrolytic or ionic dissociation or ionisation." Although introduced by Clausius in 1857, it lay dormant until it was reintroduced and applied by Arrhenius in 1884, who gave to the hypothesis a quantitative form; but it did not become popular until 1887, when Van't Hoff introduced the conception of osmotic pressure. The successful application of the hypothesis in explanation of the abnormally high results obtained in the case of conducting solutions at once secured for it a very large measure of support. Whatever view may ultimately be taken of the hypothesis—whether it be retained as a permanent addition to our theories or not—its introduction has been eminently fruitful of results, and an already too voluminous literature of the subject has grown up with surprising rapidity. Yet it appears to me that it has been accepted by a particular school—at the head of which stands Ostwald, and who regard and treat all unbelievers as heretics worthy of the stake—not as a mere working hypothesis, but as an absolute creed, without any sufficient attempt having been made to discuss its *general* probability. And the application of Avogadro's axiom to solutions, however successful as affording a mathematical method of discussing results, in principle involves the complete disregard of the essential difference between the liquid and gaseous states, and of the fact that in liquids the molecules are subject to a control which they mutually exercise and which distinguishes the liquid from the gaseous state. Also, it must not be forgotten that the arguments made use of apply almost entirely only to weak solutions—to solutions to which a law of simple proportionality may be expected to apply: that, in fact, the region explored is one in which the rate of change is represented practically by a straight line. Lastly, it is applicable only to electrolytes. Personally, I am still entirely unconvinced of the validity of the hypothesis, although no one can be more willing to admit that in so far as *weak* solutions are concerned, a "law" has been discovered which is broadly true *in mathematical form*, however open to question the fundamental premises may be on which it is based. I am satisfied, also, that the phenomena of chemical charge are as a rule far more complex in character than is assumed by the advocates of the hypothesis.

If electrolysis, and, therefore, electrolytic conduction, be—as I contend, and have long contended—conditioned *by a conjoint influence* exercised by the solvent, A, and the dissolved substance, B, there is, I imagine, no reason why other phenomena in which the conjoint influence of A and B comes into account should not be expressible in mathematically similar ways. In extenuation of such heresy I can only quote Clerk Maxwell's argument that if in a battery a septum be used which diminishes the diffusion, it is probable it will increase in exactly the same ratio the resistance of the element, because electrolytic conduction is a process the mathematical laws of which have the same form as those of diffusion, and whatever interferes with one must interfere equally with the other, the only difference being that diffusion is always going on whilst the current flows only when the battery is in action.

It has always appeared to me that the chief objection to be urged against the ionic dissociation hypothesis is the fact that, of the very large number of compounds known to us, extraordinarily few are electrolytes—not even metallic chlorides generally are conductors, but only a very limited number, and it is particularly remarkable that whilst such inactive substances as lead and silver chlorides, when fused, are among the best conductors known, aluminium chloride—one of the most active compounds with which we are acquainted—is apparently not an electrolyte. Electrolytes are clearly a very limited class, and if we consider the general properties of compounds which conduct more or less readily, whether alone or in solution, and contrast them with compounds which are practically dielectrics, it is impossible to discover any good reason why "ionic disruption" should take place in the case of the one set and not in that of the other. And if, confining our attention to acids, we contrast those which in solution are apparently good conductors with those that are bad conductors, there is again no satisfactory "motive" for so considerable a difference discoverable; for example, taking sulphuric and acetic acids, why should the former suffer ionic dissociation so readily and to so considerable an extent and the latter to so slight an extent. I imagine that it is fair for this purpose to regard the acids as modified water, and to assume that the slight tendency of water to undergo ionic dissociation—of which more later

* Presidential address delivered before the Chemical Society.

† "Hitherto chemists have only employed the two ideas of chemical affinity and the amount of chemical action, but we have shown that these ideas are simplified when regarded as E.M.F. of contact and currents of electricity. To connect the two ideas we have a third—viz., *resistance*, and the electrical law of Ohm becomes the chemical law—*the quantity of chemical action in unit time equals the sum of a great number of terms, each of which is an E.M.F. divided by a resistance.*"—Ayrton and Perry, *Proceedings*, Royal Society, 1887, 27, 227.

Digitized by Google

on—is enhanced by the association of the water with the oxygenated group, and that whereas sulphuric anhydride has a marked effect, acetic anhydride has a very slight one. Yet this is hardly satisfactory, and would probably involve the conclusion that sulphuric acid should diminish in conductivity as the temperature is raised, as it then dissociates into anhydride and water. The very different behaviour of sulphuric and acetic acids when vaporised, the former, but not the latter, undergoing dissociation, may be regarded as an indication that a similar change does not take place in the case of acetic acid, and, therefore, it might be supposed that acetic acid would undergo ionic dissociation to a far greater extent than is assumed to be the case as a consequence of the anhydride retaining its influence.

It may possibly be contended, as it has been in the case of water, that compounds generally are conductors to a very slight extent, but as all bad conductors seem to become worse conductors as they are more carefully purified, the burden of proof rests upon those who make such an assertion ; and it is not in accord with the fact that very many such compounds are as active as compounds which conduct well, and which are therefore, by hypothesis, more or less fully dissociated. For example, acid chlorides generally act on alcohols generally with very considerable readiness under conditions under which the halhydrides produce but a slight effect.

With regard to water itself, to argue, as Arrhenius, Ostwald, and others have done, from the hydrolytic action of water on the salts of weak acids and bases, that water to a certain but very small extent contains ions—that is, H and OH—is but to beg the question entirely, and a clear case of reasoning in a circle.

The recent redetermination of the electrical conductivity of water by F. Kohlrausch and Heidweiller gives the value $0{\cdot}04 \cdot 10^{-10}$ at 18deg., instead of $0{\cdot}25 \cdot 10^{-10}$ previously arrived at by F. Kohlrausch. These authors have deduced from their results a value for the conductivity of *pure* water — viz., $10^{10} \cdot \kappa = -0{\cdot}0361$. They calculate that if this conductivity be due to the presence of water ions, a cubic metre of water at 18deg. would contain 0·08 milligramme of dissociated hydrogen ions ; and point out that if present only in this excessively minute proportion, there would still be milliards of atoms of hydrogen per cubic millimetre, and neighbouring atoms would be separated by distances of the order of light waves in dimension. These conclusions, however, are based on the acceptance of the view put forward by Arrhenius, that the dissociated ions alone conduct the current—from my point of view, therefore, it is a case of deducing one unknown with the aid of another unknown—of proving one assumption by another assumption, which is admittedly an unsatisfactory proceeding. I venture to think that it is still open to question whether pure water—indeed, whether any *pure* substances outside a very limited number perhaps, such as the silver haloïds, etc.—be an electrolyte. Minute in the highest degree as the amount of impurity in the water examined by Kohlrausch and Heidweiller must have been, yet even this may have exercised a very considerable effect, and, in fact, there is clear evidence in the paper that an extremely minute amount of impurity does so act. Moreover, the difference between the lowest observed value and the corrected value appears disproportionately small when the reduction of the value previously obtained by Kohlrausch, effected by the removal of what, after all, must have been a very minute amount of impurity, is considered. The point is one of the utmost importance, and cannot be lightly brushed aside.

The methods made use of in calculating the amount of ionic dissociation of water are apparently all open to the criticism that they are based on eminently hypothetical premises, and it is particularly open to question whether the phenomena from which fundamental values have been deduced have received the proper interpretation. For example, the origin of the E.M.F. developed in liquid couples such as have been studied by Worm Müller, and much later by Nernst, and of the concentration currents of von Helmholtz, is by no means clear. Nernst assumes that in such cases forces acting at the electrode surfaces are entirely eliminated, but, if so, it is not clear why any more than when an acid neutralises an alkali an E.M.F. should be developed, for I imagine that in all such cases the changes take place within closed circuits. In fine, I am inclined to doubt whether polarisation effects can be regarded as eliminated ; the enquiry must be included with that into the existence of a true contact difference of potential independent of chemical change. The values deduced by Ostwald are based on the study of couples of the form : platinum-hydrogen | acid | alkali | hydrogen-platinum, and it is assumed that the E.M.F. developed is due to the formation at the one electrode of water from the hydrogen and the OH ions in the liquid, and at the other of hydrogen from hydrogen ions in the liquid and the hydrogen of the electrode. Unfortunately the description promised of the experiments has not yet been given, and it is therefore difficult to criticise them ; it is not impossible, however, that the real cause of the E.M.F. was dissolved oxygen.

Pure liquids do not conduct, according to Kohlrausch, because (as Ostwald has put it, "Brit. Assoc. Report," 1890, 335) their molecules have no space within which to resolve themselves into ions, and it is therefore not improbable that water would conduct electrolytically—and I presume that Ostwald meant even to imply that it would be a good conductor, as he immediately afterwards spoke of water, too, containing ions to a certain but very small extent, if we could find a suitable solvent for it. But we never have found a suitable solvent, unless it be hydrogen chloride. The fact that single substances such as the silver haloïds, when liquefied, readily conduct would appear in itself to be a sufficient argument in controversion of Kohlrausch's explanation of the influence of the solvent. Moreover, it is to be supposed that any liquid capable of acting as a solvent should condition electrolysis if the function of the solvent be but to act as a screen.

As a matter of fact, there is good reason to think that among liquids *water is the only effective solvent that we can use* !

Alcoholic and some other solutions, it is true, conduct more or less well, but it is by no means improbable that when every precaution is taken to deal with highly-purified materials, and especially to dehydrate the alcohol as fully as possible, such solutions will be found to be practically destitute of conducting power. This is the more likely now that Perkins has established the incorrectness of the supposition that until recently has always been made that hydrogen chloride, when dissolved in alcohol, acts fairly readily on it (*Trans.*, 1894, 23). The observations made by Coldridge showing that solutions of hydrogen chloride in stannic chloride are but slightly conductive, are also significant (*Phil. Mag.*, 1890, 29, 383).

If it be assumed that even pure water is to some slight extent dissociated, it is, at least, probable that liquid hydrogen chloride would contain some small proportion of ions prior to admixture with water, and, in point of fact, it is impossible to urge any reason why the one compound should be regarded as more dissociated than the other in the pure state. Yet the "ionists" not only assert that when hydrogen chloride dissolves in water it becomes almost completely separated into its ions, but make the arbitrary assumption that practically it alone is dissociated, the extent to which the water is dissociated being, indeed, diminished by its admixture with hydrogen chloride, according to their view. This question is of fundamental importance as bearing on the validity of the argument on which Ostwald and others have sought to base a method of determining the heat of formation of water from its ions and on the interpretation they have given of the changes attending the neutralisation of acids by alkalies.

I long ago insisted that we have no right to draw any marked distinction between hydrogen chloride on the one hand and water on the other, inasmuch as, in so far as the chemist can test them, they do not differ markedly in stability. I venture to think that no sufficient answer has been made to my objection. To say that analogous compounds such as NCl_3 and PCl_3, or N_2O_5 and P_2O_5, exhibit differences equal to those manifested between HCl and H_2O is incorrect and beside the point—they are vastly different in stability ; water and hydrogen chloride are not (compare Ostwald, *Ze t physikal. Chem.*, 7, 418). So long as it was asserted that water, *per se*, underwent no change, the position was, perhaps, in a measure defensible ; but when it is argued that pure water does dissociate into its ions, this advantage is sacrificed ; the possibility of a change taking place in pure water being granted, it is no longer justifiable to draw a hard and fast distinction between water and hydrogen chloride. This argument is most materially strengthened by the fact that the majority of compounds are not electrolytes.

Although those who uphold the ionic hypothesis regard the solvent as mainly inactive, yet they do not deny that it may exert some influence comparable with that exercised by raising the temperature (compare Ostwald, *Zeit. physikal. Chem.*, 1891, 7, 421 ; *Lehrbuch*, second edition, 1, 776). But it is impossible to gainsay that it has an altogether extraordinary effect in many cases. For example, in the case of hydrogen chloride, it is only necessary to mix this with nine molecular proportions of water to obtain a solution of maximum conductivity, in which, if we are to believe the ionists, nearly the whole of the dissolved hydrogen chloride is resolved into its ions. It is scarcely conceivable, however, that so small a proportion of water molecules should suffice to practically entirely prevent the reunion of ions which cannot by hypothesis be kept apart in the absence of the solvent ; and the conclusion is the more striking if it be remembered that, according to Ostwald, hydrogen silicon fluoride only begins to undergo hydrolysis when present in a solution to the extent of less than 1 per cent., a very large proportion of water being required to prevent the reversal of the interchange $H_2SiF_6 + 2H_2O = SiO_2 + 6HF$; in other words, a compound which is almost generally regarded as a molecular compound is far less readily broken up* than one of the most stable of "atomic compounds."

* Incidentally it may be asked, how is the formation of hydrogen silicon fluoride from solid silica and hydrogen fluoride to be explained, and how are we to reconcile the fact that action takes place with such extreme readiness when hydrogen fluoride is by hypothesis so slightly dissociated ?

Digitized by Google

Or, taking the case of sulphuric acid, how are we to satisfactorily explain by the ionic dissociation hypothesis the fact established by F. Kohlrausch that the amount of acid required to form a solution of maximum conductivity increases as the temperature rises from 30·2 at 0deg. to 35·4 per cent. at 70deg. ? If, however, electrolysis occur within a system of acid and water molecules, as a rise of temperature would promote the occurrence of dissociation in such a system, a larger proportion of acid would be required at higher temperatures to maintain the system of the same average composition.

In fact, I believe it is impossible to deny that the solvent is intensely active, and that it is no mere screen preventing re-combination of the ions—it is rather to be supposed that the occurrence of electrolysis in a solution of hydrogen chloride, for example, is in some way directly conditioned by the conjoint influence of the solvent and the dissolved substance ; that electrolysis is not merely an affair of atoms, of ions, but of complex molecular systems ; and, most important of all, *that water, perhaps, is altogether peculiar among solvents as furnishing solutions which can be electrolysed.*

Having thus considered some of the apparent anomalies of the ionic dissociation hypothesis, I may now briefly refer to evidence of its insufficiency in the case of interactions in which substances are concerned which are not electrolytes—a condition which is not fulfilled in the case of a very large number—indeed, an overwhelming majority—of carbon compounds. No doubt it may be asserted that, at all events, the agent used is dissociated, and that, consequently, the compound which is attacked is subject to the action of the ions just as the zinc is in a voltaic cell.

But is this a sufficient explanation ? Consider the case of the hydrolysis of sugar—admitting, for the sake of argument, that when this is effected by dilute acid, the ions of the acid and of water either simultaneously or successively attack the sugar molecule—how are we to explain the action of the enzyme invertase ? This cannot well be regarded as an electrolyte ; and it is not sufficient even to assert that it does, to some slight extent, undergo dissociation into ions—it acts so readily, more readily even than an acid which, by hypothesis, is to a very great extent dissociated, that if at all dissociated it is presumably highly dissociated. The selected action of enzymes on glucosides, etc., is also very remarkable, as acids do not act selectively.

Difficulties such as appear to beset the ionic dissociation hypothesis are not met with in considering the alternative *association* hypothesis, and if this can be shown to be compatible with electrical requirements, it should command more general consideration—in fact, there have been many indications of late that this view is once more coming into prominence. Briefly stated, the hypothesis involves the assumption that complication, not simplification, precedes most, if not all, chemical changes ; that complex molecular systems are first formed from the interacting substances, and that these on breaking down suffer rearrangement of the parts, such rearrangement taking place in consequence of elements which were previously separate being brought into one common "sphere of activity" within which it is possible for them to interact. The function of condensing and other agents—of catalysts generally—on this hypothesis is that of collecting into one system the various elements necessary for the occurrence of a particular change. Such systems may be regarded as, and, in fact, would be, closed voltaic circuits or potential circuits requiring only the removal of a resistance to convert them into closed circuits. The action of aluminium chloride, for example, in conditioning the formation of homologues of benzene from the two substances benzene and methyl chloride—both undoubtedly dielectrics, I imagine, which when together alone are entirely without action on each other—may be ascribed to the formation of an unstable compound of both with the metallic chloride. In like manner it may be supposed that ferric chloride conditions the interaction of bromine and benzene by combining with both, and so bringing them both within each others range in an unstable system. The function of enzymes in promoting hydrolysis, referred to above, on this hypothesis, consists in bringing water into conjunction with the carbohydrate by combining with both. Lastly, if it be assumed that a solution consists of dissociable molecular compounds of solvent and dissolved substance, the occurrence of change on dissolving two substances in a common solvent, as in the case of methyl iodide and silver nitrate in alcohol, may often be conditioned by the solvent acting as "condensing agent" or catalyst.

Prof. Fitzgerald, who has carefully considered this hypothesis, if I rightly understand his argument, seems to see no difficulty in applying it to the explanation of electrical phenomena. The modification of Grotthus's hypothesis which he has suggested is certainly one which appears to be in entire harmony with chemical experience, and it is so important that the question should be fully discussed, that I venture to quote his statements almost in their entirety from the "British Association Report, 1890," 142, where they are too likely to escape general attention :

"Electrolysis has been explained on two different theories by Grotthus and Clausius. As generally received they differ. Grotthus's theory, as generally given, assumes that the molecules in an electrolyte are both polarised and moved by the electric forces within the liquid. This seems so far untenable that it would appear that double the electric force would double both the polarisation and the motion of the molecules, and so should produce four times the electrolysis. The objection, however, assumes that we know the causes resisting the motion, and with proper and not very improbable assumptions as to the resistance to motion depending on it and on the polarisation, a linear relation between current and E.M.F.—*i.e.*, obedience to Ohm's law seems possible. A modification of Grotthus's hypothesis in the direction of Clausius's is, however, possible. Suppose that when polarised, the molecules *drew one another apart* at a rate proportional to the polarisation. This at once makes the relation between electric force and the decomposition a linear one, and so satisfies Ohm's law in the case of small currents. It also, so far, agrees with Clausius's hypothesis that it explains electrolysis and double decomposition as properties of the same kind. The molecules in a liquid will occasionally be arranged by accident in a proper polarised condition in a closed circuit for drawing one another apart ; and if the circuit includes molecules of different kinds, there will result double decomposition. There seem to be very serious difficulties in supposing that uncombined atoms are for any finite time free in the liquid ; and the supposition that it is a particular arrangement that is required before exchanges take place, and that with this arrangement exchanges take place of their own accord, seems to explain electrolysis and double decomposition without supposing free atoms to exist within the liquid. . . . . There are some other phenomena that have been explained upon the supposition that free atoms are gadding about in a liquid. Such are the lowering of the boiling and freezing points by solutions of salts and their effect on osmotic pressure. If dissociated atoms are going about in a liquid as in a gas, it seems impossible but that they must diffuse at different rates ; and that this is not observed seems conclusive against the hypothesis, no matter what else the hypothesis may explain. Consider solution simply. Why does chloride of sodium dissolve in water ? There must be some strong affinity between the two of a chemical or semi-chemical nature to break up the cohesion of the crystal ; and it seems reasonable to assume that this same affinity keeps the molecules of NaCl moving about among the water molecules so that they diffuse about. Now if the forces drawing them about be independent of the nature of the molecule, most of the phenomena explained by gaseous laws are explained. Pressure of a gas depends, at any temperature, on the number of molecules and not on their kind. This is Avogadro's law, by which molecular weights are calculated ; and if the forces drawing a molecule about in a liquid are independent of the kind of molecule, the very same law of pressure would hold, the pressure forwards of molecules of different kinds would depend on their number only, and in the same way as Avogadro's law would enable molecular weights to be calculated. In this connection it is well to state that some bodies may be much better able to produce pressure than others, because of their being more easily polarised—*i.e.*, turned into an effective direction. A molecule which could be easily turned into an effective direction would be about twice as effective as a molecule which went about in a higgledy-piggledy way ; and one would consequently expect electrolytes to produce more, nearly double, the osmotic pressure that others did. As to the changes of boiling and freezing points, they seem explicable by exactly the same hypothesis. The reduction of vapour pressure by molecular affinity of dissolved salt would depend only on the number of molecules of salt if all salts have the same molecular affinity for water ; and the same would apply to the change in freezing point. Hence all these phenomena are explained without assuming free atoms, and they are all explained by what can hardly avoid being a *vera causa*—namely, whatever affinities they are that cause solution, which latter is an unexplained phenomenon on the dissociation hypothesis. That it is reasonable to think that the forces keeping the molecules of salt moving about in the water are independent of the nature of the salt, appears from various considerations. In the first place, these forces are in all probability due to the residual affinities of the non-metallic elements. These same forces are probably the cause of crystallisation. These are old suggestions. That these residual affinities should be nearly the same for different combinations does not seem at all unlikely. . . ."

I have said above that the complex systems within which chemical change is assumed to take place would be closed voltaic circuits. It is to be expected that evidence of the occurrence of electrolysis and chemical change as interdependent phenomena within such systems will frequently evade detection, as more often than not we have to do with circuits which cannot be explored ; and on this account also our power of availing ourselves of the energy of chemical change is strictly limited.

A SUGGESTION FOR TESTING STREET RAILWAY MOTORS.*

BY GEORGE T. HANCHETT.

The daily inspection to which every capable railway superintendent subjects his motors often fails to detect serious electrical defects which will ultimately prove destructive. The necessity for this inspection is just as great as that for a mechanical inspection, but the time that it has required hitherto has practically barred its general practice. The object of this article is to describe an apparatus which is designed to effectively accomplish a thorough electrical testing of the car in a systematic manner, the amount of time consumed being negligible. Fig. 1 shows an elementary diagram of the circuits. A small room or shed about the size of a switch-tender's house is located near the entrance of the car-barn, and in it is stationed the inspector. By means of a single-pole double-throw switch he connects a section of trolley wire near the entrance to the terminal at his operating table One terminal is connected directly with the ground. Thus it is practicable to run a car on the siding, cut that section of trolley wire off from the balance of the system and put the car through a cycle of tests. Then by throwing back the single-pole switch, live current is once more supplied to the car, and it is allowed to pass on, either in or out, as the case may be. By a judicious choice of instruments the testing may be conducted with great facility. The requirements are a low-reading voltmeter, an ordinary 500-volt

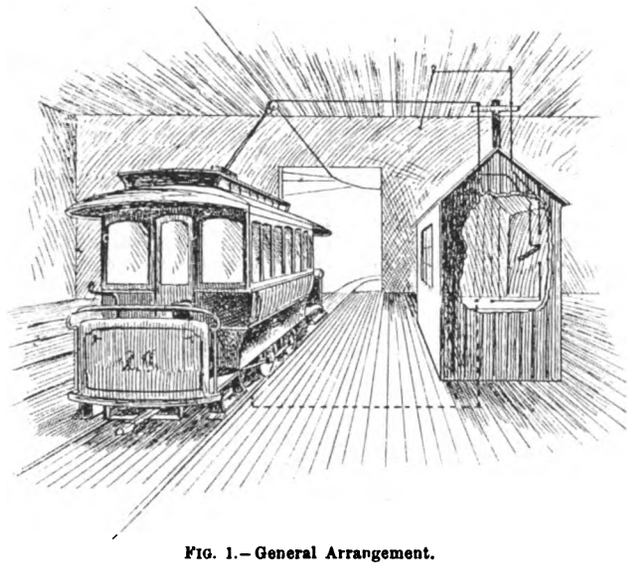

FIG. 1.—General Arrangement.

instrument, a few storage cells and a special connection with the railway circuit The apparatus may be conveniently arranged as in Fig. 2. B represents a storage battery, and it is important that when the switch, *b*, is closed the deflection of V should always be the same and practically equal to the maximum deflection of which it is capable. Thus care must be taken so that the cell is at all times normally charged, but as the amount of current taken from it is very small indeed, one charging should last several weeks Whenever a car equipment is interposed between the trolley and the ground with the voltmeter and storage cell in series, as shown in the sketch, a certain deflection will result, and as the resistance of the equipment is varied by throwing the controller from notch to notch, other deflections will follow which should always be very nearly the same if the car is in good order. If the resistance of the voltmeter is properly proportioned, very slight variations in the resistance of a car on its various controller notches can at once be detected. If a car be run on this section of wire at night and tests out with approximately the same voltmeter deflections that were obtained in the morning upon the various notches, it is pretty safe to assume that the motors are electrically intact. It is particularly to be remembered that relative deflections of the voltmeter are all that are necessary for a complete record. Actual values of resistances need not be sought, as the test is to detect any variation of these from the original condition.

*From the *Electric Railway Gazette*.

In the test for insulation resistance on the ordinary trolley system, the fact that one terminal of the car circuit is grounded necessitates a special switch on the car which shall break the ground connection. Fig. 2 includes an arrangement of apparatus suitable for this measurement. The 500-volt system is grounded through a series of lamps and a water rheostat. A wire from *c* is connected between two lamps near the positive side, and the water resistance, *r*, is manipulated until a certain predetermined potential is indicated upon E, say an even 500 volts. The controller being full on and the ground circuit on the car being broken, throw the switch, C, to its other contact; the low reading voltmeter will at once indicate. Suppose that the minimum insulation resistance allowed be 500,000 ohms, and that the voltmeter has a resistance of 500 ohms and a range of two volts. The other resistances of the circuit are negligible by comparison. Then if 500 volts be applied to 500,500 ohms a current of ·000999 ampere will flow This will deflect the voltmeter 0·4995 volt.

Thus it will be seen that a deflection of ·499 indicates 500,000 ohms. Anything less is of course to the gain of the equipment, and a greater deflection shows that the car does

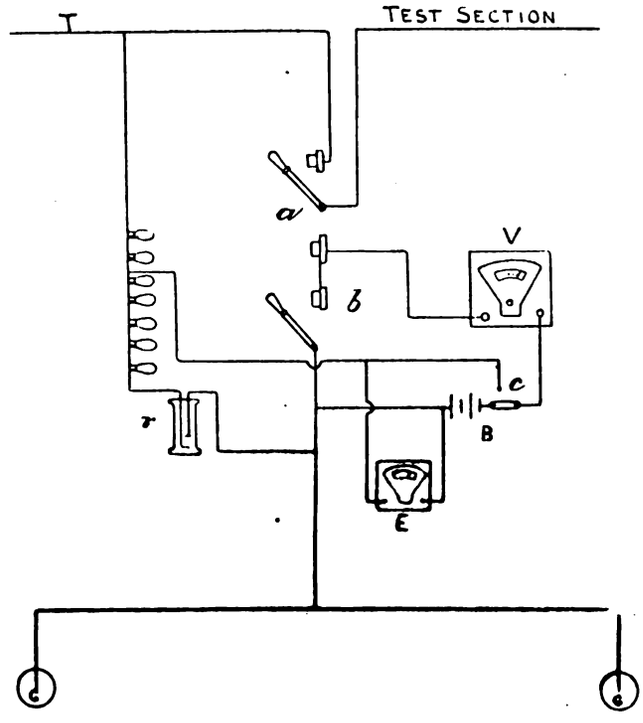

FIG. 2.—Diagram of Circuits.

not come up to the standard. By means of a little calculation and experiment with a car whose equipment is known to be intact, the standard deflection for every notch of the controller should also be obtained and proper limits of variation should be set. With a skilled manipulator the tests should not detain a car more than a minute, and this being the case it is perfectly feasible to test the car in the morning when it goes out and in the evening on its return. By this simple means, short-circuited coils, weak fields, poor contacts at controller fingers or motor brushes, open circuits, weak spots in the insulation can not only be detected, but the day on which the trouble occurred will also be recorded and the reponsibility will be more easily placed The whole outfit of testing instruments may be installed at a very low figure, and the saving in motors and repairs should amply justify the expenditure.

COMPANIES' MEETINGS AND REPORTS.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY, LIMITED.

The second ordinary general meeting of this Company was held on Monday at Winchester House, E.C., the Right Hon. Lord Rathmore presiding.

The **Chairman**, in moving the adoption of the report and accounts, a copy of which appeared in our issue of March 27, said that he

Digitized by Google

thought the shareholders might feel reasonable satisfaction as to the past and increased confidence as to the future. During the period with which the report had to do they had had to deal with some difficulties and to submit to some disappointments and delays such as were almost inevitable in the earlier stages of an undertaking, but they might congratulate themselves that though the Company had been less than two years in existence it already stood upon solid ground. It had already established and possessed a large and important business, and they had good grounds to anticipate that ere long the Company would prove to be a prosperous and very lucrative undertaking. The net revenue for the year 1895 had proved to be sufficient to pay in full the dividends upon the preference capital and to carry forward a substantial balance to the accounts of the present year. That revenue had been earned under circumstances of some difficulty, which, though of a temporary and accidental kind, were still such as to give a good deal of trouble. In reference to certain items in the accounts, under the head of liabilities, an item, "loans against security," referred to amounts received from their bankers in anticipation of the calls upon their preference share issue, and also as against the security of certain investments which the Company had made in quoted stocks. Those investments were steadily rising in value, and it was thought better to postpone selling them until the dividends which were accruing upon them had been received. They had since been sold at a considerable profit, which would go into the accounts of the present year, and, in order to give honour where honour was due, it was right to say that for the success of that operation they were indebted to the deputy chairman (Mr. Braithwaite). The next item was sundry creditors, amounting to £12,260. That sum had already been almost paid off. Turning to the assets side, the expenditures were appropriated, £75,911 to St. Luke's and Clerkenwell and £40,358 to Wandsworth. The item "sundry debtors" represented mainly debts which were due from sub-companies and for interest on advances. Practically, all those had been received since the beginning of the year. The Chairman then referred to the work of the Company as dealt with in the report. At St. Luke's and Clerkenwell, he added, the whole of the street work had been completed. By a temporary arrangement for supply of current they had been able to earn a small profit on the year. All cables had been drawn in, and the remainder of the connections with their consumers were being pressed forward as fast as possible. When their stations at St. Luke's and at Wandsworth were completed—and he expected that would be by the time the winter lighting began—they would have in the Metropolis two large generating stations, one on the north side and one on the south, built and equipped with every modern improvement, having a combined power of supplying some 90,000 lamps, and the power of each of them capable of being easily doubled simply by laying down additional plant. Under those circumstances they might fairly congratulate themselves on the satisfactory condition in which their efforts for the lighting of St. Luke's, on the one side, and Wandsworth, on the other, at present stood. Since the report had been published the provisional order for St. Olave's had been confirmed by Parliament, and had received the Royal assent. The consent of the Camberwell Vestry had been obtained, and they were in a position to secure some neighbouring districts which could all be easily and economically lighted from one generating station. In the provinces the working of their business at Bournemouth had been to some extent interfered with by the change of machinery and the rebuilding of the generating station. This entailed rather heavier expenses than had been anticipated, but, nevertheless, the gross revenue from Bournemouth did to some extent increase during the year, and the working expenses were a trifle less. With the rearrangement of the plant, and some improvements which had been introduced into the management there, the cost of production would be considerably reduced in the present year, and the net revenue increased. During the year 1895 the cost of production was ¾d. per unit less than it was during 1894, and the amount of current supplied during the first quarter of the present year exceeded that of the corresponding period by about 16 per cent. For some time the large and commodious generating station at Dover had been completed, and they had been able since that time last year to supply an uninterrupted current to consumers. Up to the present time the number of connections there was about 4 800 8-c p. lamps, and the manager thought that amount would probably be doubled by the end of the year. At Windermere seven out of the nine local authorities had given their consent to the provisional order, but two still withheld their consent, so that not much progress had been made. At Richmond, in Surrey, their investment had turned out better than was expected; for, instead of a loss of nearly £1,000, as sustained in 1894, there had been a profit of over £200 on running the station. The units sold in the quarter just ended exceeded those sold in the corresponding quarter of 1895 by about 19 per cent., while the expenses were lower, so that before long they might expect that the Richmond station would provide a satisfactory profit. In October last, their manager (Mr. Lawson) was struck down by fever, and they would have been very seriously embarrassed had not Mr. Garcke consented to give them the valuable aid of his experience. They were glad to see Mr. Lawson again with them, but they would continue to enjoy the advantage of Mr. Garcke's advice and assistance, as he had accepted the place on the Board which was made vacant by the resignation of Mr. Denny. It was in the nature of such a company as the present one that in its earlier stages the expenditure should be very heavy and the revenue comparatively small; but the Chairman believed they had already reached firm ground, and that as time went on would find the capital expenditure diminish and the revenue return increase. They had no doubt whatever that they would be able promptly and fully to meet the payments of the dividends upon the preference capital, and that before long the ordinary shareholders would also reap their reward.

Mr. J. B. Braithwaite, in seconding the resolution, said he would like to emphasise what had been said as to the expenditure in the early stages of the Company's existence A certain amount of time must necessarily elapse before the money they spent began to produce revenue. In the case of the City of London Company the supply of current was commenced in 1891, but a dividend on the ordinary shares was not paid till 1894, and then only 2½ per cent. It took another year before the shareholders received their 5 per cent., yet the City of London was considered a very successful company. It was evident that before customers could be got it was necessary to bury money in the streets in the form of conduits and mains, and to erect generating stations. Like a railway company, they must expend nearly the whole of their capital before they could earn any revenue. He would remind them that their district was many times greater than that of the City of London.

The only questions asked were by **Mr. E. R. Smart** on the subject of the item of "preliminary expenses," and by **Mr. Cash** as to the meaning of the "proportion" of directors' remuneration, etc.

The **Chairman**, in reply to Mr. Smart, said that the item referred to related to the expenses connected with the new issue of shares. That issue had been a great success, the shares standing now at a premium. In reference to Mr. Cash's question, the "proportion" was due to an apportionment of the charges between capital and revenue account.

The resolution was then carried unanimously, and the retiring directors and auditors were re-elected.

On the motion of the **Chairman**, seconded by **Mr. Reynolds**, a dividend at the rate of 6 per cent. per annum on the preference shares was declared for the six months ended December 31 last, and the proceedings terminated with a vote of thanks to the chairman and directors.

CHELSEA ELECTRICITY SUPPLY COMPANY, LIMITED.

An extraordinary general meeting was held on Wednesday afternoon at the offices of the Company, 19, Cadogan-gardens, S.W. The chair was taken by Mr. J. Irving Courtenay, and there was a small attendance.

The **Chairman** said the object of the meeting was to obtain the necessary powers for the increase of the nominal capital of the Company, as all the share capital originally authorised had been issued and fully subscribed. At the general meeting on March 4 last he laid before them fully the position of the Company, but he again called attention to some of the salient points. It was evident that with the growing demand for current in excess of the present capacity of the plant the capital outlay must increase, but the experience gained enabled the outlay to be made to the best advantage and in the most economical manner. The total number of lamps added this year up to the end of March was 4,573, as against 1,098 in the corresponding period of last year, or more than four times as many in the first three months. Formal application had been made to the Board of Trade, under the provisional order, for the whole of the remaining portion of the parish of Chelsea, and as it was unopposed they expected that the application would go through in due course. This comprised the extensive district running from Battersea Bridge along Beaufort-street and by the Fulham-road to the western boundary of the parish. The rapid increase in the demand for current in the present area and this large addition to the district supplied by the Company necessitated the immediate building of a new generating station, which would be erected on their own freehold property, and adjacent to the existing station in Manor-street, and also sub-stations for the distribution of the current. The site selected for the new generating station had space for plant having capacity for running some 50,000 8 c.p. lamps at one time, but it was only intended to erect and equip works in accordance with the demand as it arose, though the complete arrangement had been designed. The works and plant which it was proposed to erect and equip at once would furnish current to about 25,000 8-c.p. lamps fixed, and then there would be the mains and street work, which latter would be laid down with a view to carrying a larger demand as it arose. He desired to call their attention to the fact that the works costs had considerably decreased as the number of units sold had increased. During the last two years there had been a reduction in works costs of 26 per cent., and an increase in the demand for current during the same period of 43 per cent., which agreed with the experience of other metropolitan companies. Upon the general situation he pointed out that they had during the last few years been adding to their renewals fund. They had cleared their accounts of some heavy items which might legitimately have been spread over several years in a suspense account, and they had that year created the nucleus of a reserve fund to which they intended from time to time to make substantial additions. Those remarks were confirmed by the fact that since 1890 the revenue of the Company had about trebled itself, for in 1890 it was £6,080 and in 1895 it amounted to £17,165, while the amount available for interest and dividends, which in 1890 was only £597, was, as shown in the accounts to December 31, 1895, £9,595. The figures for the intermediate period also indicated how the increase of the gross revenue each year had been accompanied by a large increase in the proportion which the net revenue bore to the gross. He moved "that the capital of the Company be increased by the creation of 20,000 ordinary shares of £5 each and that the provisione

Digitized by Google

of article 4 of the articles of association of the Company shall not apply to such new shares.'

Mr. E. Garcke seconded the motion.

The **Chairman,** in reply to questions by Major Mackenzie and Mr. Andrews, said it was their intention to give a preference to the present shareholders in allotting the shares, but they did not want to bind themselves and say they would give none to the public. He thought it would endanger their interests to issue a prospectus to the public and then not give the public a chance to take any. A prospectus would be sent in due course to each shareholder, giving notice of the issues.

The resolution was carried unanimously.

A further meeting will be called to confirm this resolution, so as to make it a special resolution.

A vote of thanks to the chairman concluded the meeting.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY, LIMITED.

The report of the Oriental Telephone and Electric Company, Limited, for the year ending December 31 states that the revenue account shows a balance to credit of £8,675, which has been transferred to profit and loss. Including £706 brought forward, there is an amount of £9 381 available for disposal. The license from the Government of Ceylon expired on December 31, the Government refusing to extend it, having resolved to work the telephones through its telegraph department. The Government having declined either to purchase the Company's plant or to compensate the Company for the loss of its business, representations were made to the Government of Ceylon, which resulted in a very inadequate offer being made for the mere value of the plant. This offer the directors declined. The Board then appealed again to the Secretary of State for the Colonies, and ultimately, rather than sacrifice the property of the shareholders altogether, they agreed to accept £2,500, equal to about one-half of the capital expended on the construction. Although the transaction was only completed in January last, the directors are advised that this item in the capital account must be shown in the accounts now presented. The directors, out of the revenue, recommend a dividend of 5 per cent., free of income tax, which will absorb £8,575, and leave £806 to be carried forward. The revenues of the Indian subsidiary companies continue to improve, although the dividend received by this Company are approximately the same as those received in 1894. The expenses of the Bengal Company were temporarily increased owing to a change of manager. The Bombay Company has, after payment of the same dividend as in the previous year, carried to reserve and depreciation undivided profits to the extent of Rs.23,000 The Telephone Company of Egypt has declared a dividend of 6 per cent. as usual on the preferred shares. The China and Japan Telephone Company has had a better year, and the accounts point to an increased surplus after payment of debenture interest. The directors have agreed to extend the time for the payment of the debentures held in this Company, which fell due on December 31 last, for a further period of five years. The turnover by the electric lighting branch in India has more than doubled that of the preceding year, but the expenses incident to sending out an assistant and advertising have again caused a loss on the year's operations. The directors believe there is room for development in this branch, but have deemed it desirable to write off all initial expenses, such as those referred to, which are usually spread over a term of years.

The usual accounts are appended, and the Company's meeting will take place on April 22 at the Cannon-street Hotel.

RICHMOND (SURREY) ELECTRIC LIGHT AND POWER COMPANY, LIMITED.

The report of this Company states that "during the year a further sum of £2,906 13s. 7d. has been expended on capital account for mains and meters, and for electrical instruments in the station, the necessary funds having been obtained by loan from the County of London and Brush Provincial Electric Lighting Company, Limited. The revenue account for the year 1895 shows a profit of £230. 2s 1d, as against a loss of £978. 19s. 8d. in 1894, while legal charges in connection with the adjustment of contractors' claims, amounting to £131. 16s. 2d., liability for the greater part of which had been incurred in the previous year, have been paid out of revenue. The total number of lamps connected on December 31 last was equivalent to 5,486 of 8 c.p., being an increase of 1,746 since December 31, 1894, and a considerable additional number have since been applied for and connected in the enlarged area of supply in which mains were laid towards the end of the year. Application has been made to the Richmond Corporation for power to still further increase the area of supply; their consent has been obtained, and mains will be laid during the current year in several of the better residential streets. The machinery and the batteries in the generating station are in excellent working order, and as the capacity thereof is sufficient to meet a greatly increased demand, no further expenditure for plant will be required this year." The total quantity of Board of Trade units generated during the year was 89,698. The meeting of the Company was held on Thursday afternoon at Moorgate-court, E.C., but the Press were not admitted.

Nuremberg.—The Schuckert Company have increased their capital to 6,000,000 marks.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Coventry.—Tenders are wanted by May 12 for boilers, engines, and alternators for the Corporation. Particulars will be found in our advertisement columns

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadrath, Prague.

Liege.—Tenders will shortly be wanted in connection with a temporary central telegraph office (about £245). Address, M. le precepteur des Télégraphes, Liège, centre Belgium.

Bruges.—Tenders are wanted by May 13 for the supply and erection of an electric water-level indicator for the River Lys. Particulars from Le Gouvernement Provincial, Bruges, Belgium.

Chapelle-lez-Herlaimont.—Tenders are wanted by May 15 for erecting three lightning conductors on the Hôtel Communal. Address, M. le Bourgmestre, Chappelle-lez-Herlaimont, Belgium.

Elberfeld.—Tenders are wanted by April 20 for the supply of four engines and dynamos and 174 lamps, conductors, etc, for the Prussian State Railways. Address, die Königliche Eisenbahn-Direktion, Elberfeld, Germany.

Sunderland.—Tenders are invited by April 29 for an evaporative tubular surface condenser. Particulars can be obtained from the borough electrical engineer, at the supply station, Dunning-street, Sunderland, on deposit of one guinea.

Bedford.—Tenders are wanted for the supply of vulcanised rubber cables for the Corporation's electric lighting. Particulars can be obtained on application to the town clerk's office, Town Hall, Bedford, and tenders must be sent in by the 21st inst.

Hampstead (London).—The Vestry of St. John's want tenders for a 300-kilowatt steam alternator, feed-water heater, tank, switchboard, etc. Particulars can be obtained from the vestry clerk, at the Vestry Hall, Hampstead, and tenders must be ready by April 27

Chateau Chinon (France).—Tenders are wanted by April 19 for engineering and electrical work in connection with waterworks at Château Chinon, in the department of the Nièvre. The estimate is 43,750fr. (about £1,750), and particulars are obtainable at the Mairie, Château Chinon.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of articles and material necessary for the upkeep of their electric lighting. Tenders must be sent to the chief engineer, at the company's stores at Santa Apolonia Station, Lisbon, by May 6, and particulars can be obtained there, or at the company's Paris offices, Rue de Châteaudun 28.

Bedford.—Tenders are wanted by the Bedford Urban Sanitary Authority for the construction in various positions in the borough of five underground sub-stations. Plans and specification may be seen at the Engineer's Office, Electricity Works, Bedford, and sealed tenders, endorsed "Sub-Stations," must be delivered at the office of Mr. T. S. Porter, clerk, Town Hall, by 21st inst.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, 13, Comeragh-road, West Kensington, W., where applicants can obtain a memorandum explaining the local conditions. The tenders will be opened and considered by the Municipality of Lima, which reserves to itself the right of selecting that which is most approved or rejecting all if it thinks fit.

Bray (Ireland).—Among other articles, tenders are desired by the Town Commissioners for the supply of carbons, cables, house wires, switches, fuses, incandescent lamps, lampholders, casings, insulating materials, etc. Particulars, together with form of tender, can be obtained on application to Mr. P. MacDonnell, town clerk, Town Hall, Bray. Tenders, which must be on prescribed form, to be delivered to the town clerk, properly sealed and endorsed, by 10 a.m. on 20th inst.

Rathmines and Rathgar.—The Town Commissioners want tenders by April 20 for the electric lighting of the new town hall (about 250 lights, with engine and dynamo), and also for telephones and electric bells. Plans and specifications can be seen at the office of the secretary to the Commissioners, Town Hall, Rathmines, Ireland, or copies will be supplied on payment of 10s., and tenders, in sealed covers, endorsed "Tenders for Electric Lighting," must be sent to the above address by April 20 at 10 a.m.

Hull.—Tenders are required for the supply of coal from May 1 to December 31, 1896, for the Electric Light Committee, in accordance with the conditions set forth in the forms of tender, which may be obtained at the electric light station, Dagger-lane. The contractor will have to enter into the usual form of contract required by the Corporation. Tenders, endorsed "Steam Hards for Electric Light Station," should be sent under seal to the Chairman of the Electric Light Committee, Town Hall, Hull, by noon on 30th inst.

Digitized by Google

St. Helier (Jersey).—Persons wishing to establish a lighting station in the locality for the purpose of supplying electric, gas, or other forms of light, for both public and private use, are requested to communicate with Mr. P. Baudains, constable, Town Hall, St. Helier, Jersey. All such preliminary communications are to state (1) form of light—*i.e.*, whether electric, gas, etc.; (2) in the case of electric light, what methods of generation and distribution would be adopted; (3) proportionate price for public purposes and private lighting; (4) general conditions under which tenders would be made. All necessary information will be supplied on application.

Antrim.—The Commissioners for the Control of Lunatic Asylums will receive sealed tenders up to 10 a m. on May 1 for the supply and erection of an electrical installation at County Antrim Lunatic Asylum. The tender should be sent in a sealed envelope, endorsed outside "Tender for Electric Lighting, County Antrim Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and should be accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate Forms of tenders, and copy of specification, which has been prepared by Mr. J H. Greenhill, M I E E, will be issued on application to the office of the Board of Control of Lunatic Asylums, Dublin, on deposit of £3, which will be returned to all persons who have sent in bona fide tenders. Plans can be seen at the office of the architect, Mr. John Lanyon, Northern Bank-chambers, Royal-avenue, Belfast.

Shooter's Hill (London).—Tenders are wanted by May 6 for the provision and fixing of electric bells, telephones, fire alarms, etc., at the Brook Fever Hospital, Shooter's Hill, S.E., for the Metropolitan Asylums Board. Copies of the specification form of tender, conditions of contract, and of the drawing, which have been prepared by Prof. Kennedy, LL.D., F.R S., of 14, Old Queen-street Westminster, S.W., can be obtained at the chief offices of the Board on and after 16th inst. upon depositing gold or Bank of England note to the value of £5 (which will be returned only to those who send in a bona fide tender in accordance with the terms of this advertisement, and who return the drawing, specification, and conditions of contract). Tenders, which will only be received on the lithographed form supplied by the Board, must be sealed and endorsed "Tender for Electric Bells, Telephones, etc , Brook Hospital," and must be delivered at the Chief Offices, Norfolk House Norfolk-street, W.C., by 2 p m. on May 6. Unless the tender be accompanied by the specification, conditions of contract, and the drawing it will not be considered.

RESULTS OF TENDERS.

Harrogate (Yorkshire).—The tender of the Liverpool Gas Fittings Company, at £1,293, was accepted for an electric light installation (about 400 lights) including generating plant, also telephonic and bell installations, at the Prince of Wales Hotel.

Sunderland.—The accepted tenders for the plant required at the electric supply station by the Corporation were as follows: for two steam-engines and continuous current dynamos, with steam and exhaust pipes and switchboard extensions, T. Parker, Limited, Wolverhampton; two water-tube boilers of Babcock and Wilcox type. Babcock and Wilcox, Limited, London; fuel economiser, E. Green and Son, Wakefield; a cast-iron tank, H. Tonkinson, Sunderland.

Newtown (Montgomeryshire).—Among the accepted tenders for work in connection with the erection of a factory for Messrs Pryce Jones, Limited, were the following:

L. G. Tate, London, telephones and bells	£48	0	0
Crossley Bros., Manchester, gas-engines, etc., for electric lighting	457	0	0
J. A. Edmondson, Leeds, wiring, etc.	325	0	0

BUSINESS NOTES.

Monmouth.—The Local Government Board have granted the Corporation powers to borrow £8,115 for electric lighting.

Nottingham.—The spacious goods warehouse which has just been erected for the Midland Railway Company is lighted by electricity.

Eastern Telegraph Company.—The receipts for the month of March were £81,135, as against £70,470 for the corresponding period of 1895.

Motherwell (Lanark).—The Police Commission have postponed consideration of the electric lighting scheme, which was estimated to cost £8,500.

Bristol.—The report of the Electric Lighting Committee, which recommends the borrowing of £75,000 for extensions, comes before the Council next week.

Worthing (Sussex).—The Urban Council have in contemplation the erection of public baths, which it is proposed to light by electricity at a cost of £400.

Cupar (Fife).—The Standing Joint Committee have decided to bring the question of the charge for the use of the telephone for police purposes before the County Council.

Train-Lighting.—The North British Railway Company are about to run between Edinburgh and Glasgow an experimental train lighted by electricity on Mr. A. B. Gill's (Messrs. Stone and Co.'s) system.

Western and Brazilian Telegraph Company.—The receipts for the week ending April 10, after deducting 17 per cent payable to the London Platino-Brazilian Telegraph Company, amount to £2,375.

Useful Notes.—We have to acknowledge the receipt from Messrs. Pitt and Scott, 1, Cannon-street, of a copy of "Useful Notes," a waistcoat-pocket companion of information for travellers in Europe.

Cheltenham.—If the experimental lighting in the South Ward is a success, it will be extended to other parts of the town. The dust destructor is doing its duty satisfactorily as a power generator.

Battersea (S.E.).—The question of lighting the Municipal Buildings by electricity has been referred to the Electric Lighting Committee, whose report is expected to be presented at the next meeting of the Vestry.

Portishead (Somerset).—The Urban District Council have instructed the surveyor to make enquiries and report as to the advisability of adopting the electric light. The town has a population of about 3,000

Southend.—Notwithstanding the fact that Prof. Kennedy is preparing a report on the advisability or otherwise of lighting the town by electricity, the Town Council have decided to light the western esplanade with gas.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending April 12 amounted to £1,469, as compared with £1,243 in the corresponding week of the previous year, being an increase of £226.

Llandudno.—The District Council have adopted the report of Mr. A. H. Preece relative to the lighting of the town by electricity, and decided to borrow £25,000 to carry out the scheme, in accordance with a provisional order obtained last year.

Great Northern Telegraph Company.—The net receipts during 1895 including the balance brought forward, amounted to £381,583. The Board propose to pay a final dividend making the total dividend for the year 10 per cent., carrying £58,055 forward.

St. James's and Pall Mall Electric Light Company, Limited.—The sale of electricity for the three months ending March 25, representing the supply at 6d. per unit, amounted to £16,862, as against £13,907 at the same rate for the corresponding quarter of 1895.

Taunton.—The expenditure in the electric lighting department for the year has been £3,004. 13s 3d, and the total income £3,580. 11s. 11d, a profit on the year's working of £575 18s. 8d. The Town Council have decided to borrow £3,000 for additional works.

Chester.—The contractors, Parkers, Limited, Wolverhampton, have commenced operations for the erection of the central-station building in New Crane-street, on the west side of the Holyhead Railway. It is hoped that the electric light will be available next winter.

Parliamentary.—On Tuesday a Committee of the House of Commons passed the Bill authorising the transfer of the undertaking of the Liverpool Electric Supply Company to the Liverpool Corporation. The Bill has now been sanctioned by both Houses of Parliament.

Voghera (Italy).—During the present year the Municipality of Voghera will be ready to consider propoeitions for a system of lighting for the town, either exclusively by electric light or by a mixed system of electricity and gas. The existing contract with the local gas company expires in 1898.

Harrogate.—At the monthly meeting of the Town Council the town clerk reported that he had received the sanction of the Local Government Board for the whole of the loans for the electric lighting scheme, amounting to about £25,000, and he was instructed to press forward the various contracts for machinery, plant, etc.

Electricity and Gold Mining.—The Hesperus Gold Mining Company, Limited, has been formed to work and develop gold mines on the East Coolgardie goldfield. to construct, maintain, and work telegraph and telephone systems, and to carry on in all their respective branches the business of producers of electricity, etc.

City and South London Railway.—The returns for the week ended April 12 were £868, compared with £779 for the corresponding period of last year, being an increase of £89. The total receipts for the half-year terminating as above were £14,339, compared with £14,362 in the same period of the preceding year, being a decrease of £23.

Glasgow.—We are credibly informed that proposals are now being entertained for the construction of several miles of electric tramway in Glasgow on the closed-conduit system for experimental purposes, and in order to show the capabilities of this particular system. Should the results prove as satisfactory as is promised it is expected that there will be considerable developments, not only in Glasgow itself, but elsewhere.

Electric Traction in France.—The work of completing the electric tramways at Angers is being pushed on in order that the opening may take place next month. The Dijon Electric Tramway Company have made a profit of 96,400fr. (about £3,856) on the first year's operations. An enquiry has been held with a view to establishing electric tramways at Limoges, and lines are now in construction at Limoges and Rennes.

Digitized by Google

Newmarket.—At the meeting of the Urban District Council a letter was read from the Board of Trade stating that in view of the opposition of the Council to the provisional order sought by the Newmarket Electric Lighting Company it would not be proceeded with.

Swansea.—The Electric Lighting Committee of the Corporation have held a meeting for the purpose of considering an offer made by Mr. J. L. Howell, of Llanelly, to purchase the powers the Corporation have to light the town by electricity. The proposal was fully discussed, but it was decided not to part with the provisional order at present.

Self-Propelled Traffic Association, Limited.—This Company has been registered by Lumley and Lumley, 37, Conduit-street, E.C., as a company limited by guarantee, with an unlimited number of members, each of whom is liable for the sum of £1 in the event of winding up. The control of the business of the Company is vested in a council.

Islington (N.).—The Electric Light Committee of the Vestry have decided to at once increase their plant with a view to extending their system of public lighting from the Nag's Head, Holloway-road, to the Archway Tavern, Highgate, and also for the purpose of supplying the light to the Northern Polytechnic in the Holloway-road and the Agricultural Hall.

Wakefield.—The Mayor stated at the City Council meeting that the County Council had recently made a direct application as to when the City Council would be able to supply their new offices with the electric light; and Alderman Sherwood (chairman of the Electric Light Committee) said they hoped before another year was over to have the electric light in full swing in the city.

Exeter.—The Board of Trade have expressed readiness to consider an application for revocation of the Exeter Electric Lighting Order, 1891, with a view to the purchase of the undertaking under Section 68, and the Town Council have decided to make the application. Sanction has also been obtained from the Local Government Board for a loan of £7,500 for the purchase-money.

Walsall.—At the meeting of the Town Council, the Electric Lighting Committee reported that the number of consumers on March 31 was 53. The committee asked for authority to have the necessary cables, poles, fittings, and lamps for lighting the bridge, Park-street, the entrance to Bradford-street, and Lower Bridge-street laid and fixed at an estimated cost of £621. 10s. This was agreed to.

Indo-European Telegraph Company.—The directors of the Indo-European Telegraph Company, Limited, after adding £10,000 to the reserve fund, have determined, subject to audit, to recommend the payment of a dividend for the six months ended December 31, 1895, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent., and a bonus of 20s. per share, both free of tax, making in all 10 per cent. for the year.

Eastern Extension Telegraph Company.—For the month of March the receipts show an increase of £6,605 as compared with the corresponding period of 1895 The accounts to December 31 show a balance profit of £210,579, after payment of three interim dividends. The directors propose to distribute a final dividend of 2s. 6d. per share, together with a bonus of 4s. per share (or 2 per cent.), making a total distribution of 7 per cent. for 1895.

Keswick.—At the meeting of the Urban Council the clerk read a letter from Messrs. Hayton and Simpson, Cockermouth, who wrote that they had received intimation that the electric lighting company's application for a provisional order would not be proceeded with or considered. Mr. Mumberson asked if that left a clear course for the Council. The Clerk replied that it would not deter the company from opposing the Council's application.

Paisley.—The Police Commissioners have decided to proceed with a public installation of the electric light. At a meeting in committee it was agreed to ask a tender from the Brush Company for wiring the Clark Town Halls, and after considering the same, it was decided to delay making any recommendation on this subject There was read a letter from Dr. Bottomley to the effect that the cost of a central installation of the electric would be £25,750.

Edinburgh.—The draft provisional estimates laid before the Electric Light Committee of the Town Council showed an estimated expenditure of £20 435, and estimated receipts amounting to £27,925. With part of the apparent surplus it is proposed to reduce the price of the current sold by meter to 5d. per unit. In 1895-96 the estimated expenditure was £13 900. In 1894 95 the actual expenditure was £4,076. 16s 10d. For 1895-96 the estimated receipts were £12,640

Acetylene Gas.—It is stated that the Acetylene Illuminating Company, Limited, of 63, Queen Victoria-street, E.C., who hold a license under the Willson's patents for the manufacture of calcium carbide and the supply of acetylene gas, have made arrangements with the British Aluminium Company by which the Acetylene Company obtain control of the Cowles and various other patents dealing with electrical furnace work so far as the manufacture of calcium carbide is concerned.

Ashton.—The Electric Lighting Committee received 19 applications for the post of electrical engineer, and in their report to the Council they recommended that Mr. S. V. Clirehugh, of Temple-chambers, Brazennose-street, Manchester, be appointed consulting electrical engineer to the Corporation. Councillor A. E. Mellor, in moving the minutes, said the gentleman appointed was a very clever man, and, as he lived in Manchester, he would be able to devote the whole of his time to the work. Councillor Kelsall seconded the motion, and it was adopted.

Ealing.—At the meeting of the District Council the Electric Committee recommended that the system of electric supply should be extended to Gunnersbury, if Mr. L. de Rothschild and the other residents who desired it would pay the interest on the capital charges, a certain sum annually for depreciation, and a minimum of £50 a year for the supply. The surveyor explained that if the proposal were adopted the sum received for the supply would be clear profit. The recommendation was adopted.

Vacancies.—The Blackpool Corporation invite applications for the post of resident working electrical engineer. Applicants are asked to state the salary required, when they will be at liberty, and to forward testimonials to the town clerk (Mr. T. Loftos) before April 27.—An assistant is wanted in the physical department at the City and Guilds Technical College, Exhibition road, South Kensington. The salary is £100, and applicants should communicate in the first instance by letter to Prof. Ayrton.

Price-Lists.—We have received a price-list from the Sunbeam Lamp Company, Limited, of Gateshead on-Tyne, and 50, Fenchurch street, E C. This firm manufactures all kinds of incandescent lamps both for high efficiency and high voltage. The catalogue is well illustrated. We have also to hand an illustrated price-list of electric light requisites from J. Sunderland and Co., Victoria Electrical Works, Halifax. The book gives prices for lamps, fittings, wire, etc., and dynamos and motors up to 42 kilowatts.

Brighton and Rottingdean Electric Tramroad. — The Unopposed Bill Committee of the House of Commons have passed the Bill granting an extension of time until July, 1898, for the completion of the authorised Brighton and Rottingdean Seashore Electric Tramroad. The Bill also empowers the Company to raise £10,000 additional share and loan capital, and provision is made to enable the Company to enter into traffic arrangements with any steamboat, omnibus, and other companies conveying traffic to and from the tramroad.

Belfast.—At a meeting of the Electric Committee the engineer submitted his report on the progress of the introduction and the possibilities of development of the electric light, with an analysis giving the expenditure connected with the production and distribution of current in different forms. He was instructed to examine and report upon sites available for the erection of a main central station, capable of extension and applicable for all the wants of the city for many years hence, in order that, should the Council decide to enlarge the producing capacity of the department, the committee would be in a position to meet the requirements.

Whitehaven.—At the meeting of the Town Council Dr. Hopkinson's report was considered paragraph by paragraph, and it was agreed that the following recommendations in the report be adopted: (1) That a subsidiary switchboard be placed near where the cables now enter the engine-house, and connected to the present main switchboard by bare copper conductors, carried above the iron tiers of the roof; and that Dr. Hopkinson be requested to prepare a specification in order that tenders may be invited for carrying out the work. (2) That disconnecting bars be placed in the present disconnecting boxes for testing purposes.

Bowness-on-Windermere. — At the meeting of the Urban District Council the clerk announced the receipt of a communication from the Board of Trade stating that the electric lighting company for this district had made an application for a further extension of time in asking for a provisional order, wishing it to be extended to October 12 next, and it was required to have the sanction or otherwise of the Council. The chairman saw no cause for any objection whatever, but thought the proper course was to leave the matter with the committee. After a few desultory remarks it was thought they might at once decide that they were quite agreeable the application should stand good.

Leeds.—At a meeting of the Sub-Highways (Tramways) Committee, Dr. Hopkinson attended, and discussed with the committee several matters with a view to the preparation of specifications of the cost of the equipment of the electric tramway system which is proposed between Roundhay Park and Kirkstall. At a subsequent meeting of the Highways Committee the minutes of the Tramways Sub-Committee have been approved, and Dr. Hopkinson appointed as engineer. Dr. Hopkinson will take the full responsibility of the equipment, and he has been instructed to prepare the necessary specifications. Mr. Hewson, the city engineer, has also been instructed to prepare plans for the power station near to Crown Point.

The Church of St. Mary Woolnoth.—Brooke *v.* the City and South London Railway Company came before Mr. Justice Kekewich in the Court of Chancery on April 14. This was a motion by the plaintiffs, the rector and churchwardens of St. Mary Woolnoth, to restrain the defendant railway company from proceeding on a notice to treat under which the company proposed to take the church for the purposes of their railway. Mr. Warrington, Q C, and Mr. R. F. Norton appeared for the plaintiffs; and Mr. Cripps, Q.C., and Mr. Ingle Joyce for the defendants. Mr. Justice Kekewich, by consent, made no order on the motion, except that the plaintiffs should pay the costs of the motion.

Cork.—A special meeting of the City Council will be held to-day (Friday) to consider and approve or otherwise of an application of the Cork Electric Tramways Company Limited, intended to be made to the Lord-Lieutenant in Council, under the Tramways (Ireland) Acts, to authorise the construction, working, and maintenance of tramways in the city of Cork, to be worked by horse power, electrical or other mechanical power, with all necessary works connected therewith, as shown and delineated on

Digitized by Google

deposited plans; and in connection with the foregoing, to consider a report of the acting city engineer. The approval or disapproval by the Council of the proposed tramways will have no effect unless it is determined by a majority of not less than two-thirds of the members present.

Derby.—Major-General H. D. Crozier, R.E., has held a Local Government Board enquiry into the application of the Corporation to borrow £13 185 for purposes of electric lighting. Mr. Harris (of the firm of Bramwell and Harris consulting engineers to the Corporation) explained that extensions had to be made at the electric lighting station in consequence of an increased demand for the current by the public. The Town Clerk said that the Local Government Board had written saying that they could not entertain the application for £419 for the purpose of obtaining powers The Inspector replied that the Local Government Board had taken counsel's opinion on the question, and this item was excluded from the present enquiry. Evidence having been taken, the enquiry terminated.

London Tramways.—In reference to the proposal for a tramway trust to manage all the London lines, it appears that the system of mechanical traction to be adopted, if the scheme is carried through, will be an underground electrical one. It is needless to say that prolonged negotiations will be requisite to carry out such a scheme, and in addition a number of private Bills will have to be carried through Parliament to give effect to the proposed amalgamation. The whole idea of the promoters is to place all the tramways of London under one control, and thus effect a network of street railroads which will give greater facilities for locomotion in the Metropolis The County Council's powers of purchase come into effect on most of the principal lines in the course of the next two years, and the idea is that by amalgamating all the lines it will be possible to give the shareholders better terms than they are entitled to under the Bramwell award.

Ayr.—The Town Council have unanimously adopted a recommendation by a committee that the Corporation should construct an electric tramway from Burns Monument to Prestwick, a distance of six miles. From a minute of the Lighting Committee, presented at the meeting of the Police Commissioners, it appeared that the clerk read a letter, dated 12th inst., from Mr. Hammond in reference to the transformers, and the committee directed that the letter be printed and issued to the committee. After discussion the committee were unanimously of opinion that Messrs. Swinburne should be required to fulfil their contract, but as other transformers are required, owing to the extensions, the meeting unanimously agreed to recommend the purchase of five transformers from Messrs. Siemens at the prices quoted in Mr. Hammond's former report. The report was adopted, and it was also decided to purchase 28 meters from the British Thomson-Houston, Limited. The Council's committee have reported in favour of an electric tramway.

Blackpool.—At the monthly meeting of the Town Council Councillor Brodie moved the adoption of the Electric Lighting Committee's report, which provided for the acceptance of certain tenders for the purposes of electrical extension. On the matter of electrical supply to the Winter Gardens, the chairman of the committee, Councillor Brodie, stated that nothing satisfactory had been arrived at between the committee and the company, and the latter intended to put down a private plant of their own before very long. Councillor Sergeneon attacked the committee's new scheme for better supplies and more efficient working, remarking that it was presumptuous to make an application for £30,000 unless they were in a position to assure the Council that the scheme was a thoroughly practicable one. The minutes were passed. A proposal was brought forward by Councillor Brodie for the lighting of Lytham-road by arc lamps instead of gas. Councillor Pagnam seconded the amendment which was carried.

Bradford. The Gas and Electricity Committee have at last decided to light some of the open spaces and more awkward crossings in Bradford with electric arc lamps. The *Bradford Observer* says that for very large spaces where traffic is heavy it has been demonstrated that the electric arc lamp (at a suitable height and properly reflected) is cheaper, light for light, than the best form of gas burner. At the meeting of the Town Council, the Town Clerk (Mr. W. T. McGowen) said that a communication had been received from the Local Government Board intimating that one of their inspectors would come down to Bradford on the 21st inst. to hold an enquiry into the application of the Corporation to borrow £40,000 for the purposes of electrical works. The minutes of the Gas and Electricity Supply Committee, which included resolutions accepting tenders for supplying and fixing machinery and plant at the new electricity works, Valley-road, amounting to £7,543. 10s., and tenders for the erecting of the buildings required, amounting to £11,448. 6s., were adopted.

Hampstead.—Harold W. Woodall has been appointed assistant electrical engineer to the Vestry in the place of W. Bathurst, resigned. The Vestry have accepted the resignation of C. O. Bastian as an assistant electrical engineer, and have authorised the Lighting Committee to appoint his successor. Pipes have been laid down in the High-road, Kilburn with the idea of drawing electric light cables through them when the Vestry decide to light the thoroughfare by electricity. At the last meeting of the Vestry, the Clerk, in reply to a question on the subject of the report on the electric lighting undertaking up to the end of 1895, said that in going through the stock-book at the central-station an error was discovered, owing to which it appeared that there was more of some kinds of material in stock now than had ever been bought. That discovery had caused some delay, but he trusted that the report would be ready by the end of the week. It was resolved to lay an electric lighting main from Alexandra-road to High-road, Kilburn, for the supply of current to private consumers in Belsize-road, at an estimated cost of £462.

Dundee.—At the meeting of the Trades Council Mr. Joseph Carr referred to the allegation made at a previous meeting that the man in charge of the engines and boilers at the electric station was not a practical engineer. He had communicated with Mr. Ballingall, the convener of the Gas Committee, and that gentleman having sent his letter to the engineer in charge of the station, Mr. Walter Brownlee had replied to the effect that two engine-drivers were employed, one of whom was a locomotive driver before he entered the service of the Corporation. The other driver was a mechanic. Both were competent men, and, so far as Mr. Brownlee was aware, it was not usual to employ engineers as engine-drivers at electric light stations. Then, further, Mr. Brownlee said the committee were evidently misinformed as to the cause of the accident which some time ago occurred at the station, as upon enquiry it had been found that the mishap could be attributed to none of the employés. However, the Board of Trade report was expected to be forwarded soon; as it would doubtless be published, the committee would then be able to make up their minds on the point.

Aberdeen.—The Electric Lighting Committee have made an inspection of the electric station in Cotton-street for the purpose of considering as to the extension of the buildings. It was recently decided to add a 300-h.p. engine to the plant, and in a report by Mr. Smith, gas manager, and Mr. Blackman, electrical engineer, issued last week, it was recommended to extend the buildings in view of future increased demands for current. Plans were submitted of the addition to the existing building, the estimated cost being put at £4,590. The committee, after inspection, were convinced that it would be utterly impossible to lay down the new engine in the present floor space, and they unanimously agreed to recommend the extension of the buildings. In the plans it was shown that the two sections of the new block would each afford space for engines with an aggregate of 2,000 h.p. The committee instructed Messrs Smith and Blackman to bring up an additional report showing the exact size of the different engines for which space would be provided. It is recommended that the mains should be extended to supply part of the west end and other districts, at a cost of £10,000

Rathmines (Dublin).—Mr. W. B. Barrington. C.E, representing the Board of Works, has held an enquiry under the Tramways Acts, 1860 and 1871. with regard to the proposal of the Rathmines, Dundrum, and Blackrock Tramway Company to run a line worked by electricity from the Big Lamp, Rathmines, to Dundrum. Mr. William Deverell appeared on behalf of the promoters of the line. Mr. Drury (instructed by Messrs. D. and T. Fitzgerald) appeared for the Rathmines Commissioners and the Pembroke Commissioners. Mr. Dixon, engineer, and Mr. Fawcett, secretary to the Rathmines Commissioners, and Mr. Manly, secretary to the Pembroke Commissioners were present. Mr. Barrington said that the present enquiry was concerned merely with the engineering aspect of the undertaking. Mr. Fuller, engineer to the promoters, was examined, and explained the details of the proposed system. The system of electricity to be used would be the overhead system, and in some places it was exactly similar to that used in the Blackrock and Dalkey line. The wires, however, would not be suspended in the same way as in the case of the line mentioned, but would depend from side brackets affixed to poles. The promoters were quite prepared to lay their line to the satisfaction of the township engineers.

Norwich.—The following report was received at the annual meeting of the Governors of the Norfolk and Norwich Hospital: "The Board beg to report that for nearly two years the subject of the lighting of the hospital, which is unsatisfactory and expensive, has been under their consideration It has been in the hands of two consecutive house committees, who have gone very fully into the matter. They have experimented in one of the wards, and in other rooms, with the incandescent gaslight, and have arrived at the conclusion that, although an improvement in brilliancy upon ordinary gas, it is not suitable for use in the hospital. Finally, they have made exhaustive enquiry as to the cost of installation and of annual maintenance of the electric light, and have found that the former, for an adequate and even liberal system, would be somewhat under £800, and the latter probably less than is annually paid for gas. The Board, therefore, in view of the superior healthiness, cleanliness, and convenience of the electric light, coupled with the fact that part of the gas system is much out of repair, suggest to the governors that it be installed in the hospital, and that the system be connected with the Norwich Electricity Company, by whom they consider it would be advisable, at any rate for a time to be supplied" The report was unanimously adopted. The electric light is becoming very popular in the town.

Guildford.—At the meeting of the Town Council the Paving Committee reported that they had considered the letter of the Board of Trade asking for any observations on the description of the system to be adopted for the supply of electricity by the electric light company, and as the system appeared to be a very usual one the committee had not considered it necessary to offer any observation by way of objection. The committee had also considered the notice received of the intention of the company to proceed with the laying of the distributing mains, and the committee do not see any reason to disapprove of the manner in which this work was proposed to be done. They thought,

Digitized by Google

however, that the company should be asked to furnish, on the completion of the works now proposed to be proceeded with, a plan on a large scale showing the exact position of their mains for future reference, and it might be found desirable to obtain the sanction of the Board of Trade to make regulations prescribing the hours during which the undertakers were to have access to street boxes. Alderman Swayne, in moving the adoption of the report, said he thought the Council ought to be very careful with regard to the wires, as they would take up a good deal of the pavement. He thought the company ought to submit plans wherever they were going to take up the pavement before it was done. Mr. Miles seconded, and the report was adopted.

New Malden (Surrey).—It was reported at the last meeting of the District Council that at a meeting of the General Purposes Committee, the clerk read letters from the town clerk of Kingston and Messrs. Trollope (on behalf of of a householder in Coombe) as to the introduction of the electric lighting into Coombe, but the letters were referred to the Council. The Clerk said that was the second occasion on which the town clerk of Kingston had written on the subject, and on the former occasion they replied that the question of electric lighting for Coombe was a little premature. The Chairman said that if they allowed Kingston to introduce the electric light into Coombe it would give them a monopoly for 42 years but by making special arrangements that term might be decreased, and they must bear that in mind. A Member asked how many inhabitants had asked for the electric light. Mr. Monro thought there were several. Mr. Monro moved, "That this Council would be prepared to give permission to the Corporation of Kingston to supply electric lighting to Ward 1 of their district if terms satisfactory to the Council could be arranged." There was no prospect of that Council being in a position to supply the electric light to these people, and they would be acting in the dog-in-the-manger manner if they did not at all events take some steps in the matter. All they needed to do was to protect themselves. Further discussion ensued upon the motion, and ultimately it was altered by Mr. Monro as follows: "That this Council will be prepared to consider favourably the application of the Corporation of Kingston to supply Ward 1 of the district of the Council with the electric light if terms satisfactory to the Council can be arranged." Mr. Salt seconded, and the motion was carried.

Maidstone.—The Urban District Council cannot make up their minds yet to part with their provisional order, although they don't want to use it themselves. At the last meeting of the Council the Electric Lighting Committee reported that Mr. Thomas King had expressed his willingness to alter the terms of his agreement as as follows: (1) To refund all moneys paid by the Council (including engineer's fees and costs), in respect of their order and the transfer of same, not exceeding £750, instead of £500, as originally suggested. (2) That the Council shall be at liberty, on the conditions mentioned in the draft agreement, to purchase the undertaking at the following periods: (*a*) in seven years on paying 30 per cent. for compulsory purchase, (*b*) in 14 years on paying 20 per cent., (*c*) in 21 years on paying 10 per cent. Alderman Ellis moved that the terms of Mr. King be accepted, and, in reply to Alderman Spencer, said if they passed his resolution they would be accepting the heads of the agreement. Mr. Baker seconded the motion, which was supported by Mr. Urmston, who objected to the dog-in the-manager policy of the Council, and maintained that they should dispose of the order to Mr. King and let him carry it out. As a ratepayer he did not want the light, and he objected to pay for it for those who did want it. Alderman Spencer was of opinion that they should not move in the matter at present, and Mr. Cox strongly spoke against the motion, maintaining that the Council should retain the order, although he did not advise them to carry it out at present. He argued that electricity was not properly developed yet, and he noticed that there were orders which had been held for over 10 years by local authorities and never disturbed. Let them wait till they were forced to do something with it. Eventually, the matter was referred back to committee.

Portrush (Antrim).—At the meeting of the Town Commissioners the clerk read a letter from Mr. W. A. Traill, C.E., engineer of the Giant's Causeway and Portrush Electric Railway intimating that he purposed attending the Board's meeting to answer any enquiries in reference to their proposed alteration of their electric system for working their tramway on the overhead system. They intended to erect iron or steel posts on the insides of the pathway, with projecting brackets to carry the conducting wire. At the curve at the Methodist Chapel they would erect an ornamental post in the centre of the triangle between the roads, and place a lamp for gas thereon, allowing a clear headway where crossing the road of 18ft. Mr. Traill was then admitted to the Board room, and explained the details of the scheme He said that at the place where the roadway was crossed he had proposed to give a headway of 20ft. to permit of the passage of vehicles, such as hay-carts, etc., but the county surveyor would be quite satisfied with 18ft. He further explained that the posts would be erected for the most part on the inside of the footpaths, with projecting arms over to the centre of the tram line. The posts would be of drawn-steel tube, 4in. in diameter at the base and 3in. at the top, and the projecting arms would be 1½in. or 2in. in diameter. Suggestions were offered by various members of the Board, after which Mr. Macaulay proposed that the Commissioners approve of the alterations, subject to Mr. Traill's assurance that nothing unsightly would be placed in the streets. He remarked that the through conveyance of passengers from the railway station would be a great improvement, as it would obviate the necessity for the stops and changes which at present occurred at the tramway depôt. Mr. Hetherington seconded the motion, which was agreed to after further conversation. Mr. Traill thanked the Board and withdrew.

Bangor.—At the monthly meeting of the City Council the reports of the Electric Lighting Committee, which were as follow, were adopted: A letter was received from Colonel the Hon. W. E. Sackville West enquiring on what terms the Council would be prepared to supply Penrhyn Castle with electricity from the proposed works. It was resolved that the Council be recommended to construct an electrical main at their own cost for the supply of electricity to Penrhyn Castle, upon Lord Penrhyn giving an undertaking as mentioned in Section 21 of the draft license of the Bangor electric lighting scheme. Tenders for contract Nos. 2 and 3 were opened by the chairman and compared. It was resolved that the whole of the tenders be submitted to the engineer, and that he be asked to tabulate the same and return them as early as possible, together with his observations thereon. Dr. H. R. Hughes wrote stating that he was prepared to give up possession of the land on receiving £10 as compensation. It was resolved that the Council be recommended to accept Dr. Hughes's offer. Dr. Grey Edwards explained the result of the interview the deputation had with the Board of Trade. He stated that the Board of Trade would direct an enquiry to be held at Bangor into the matter. Subsequently a telegram had been received from agents stating that the enquiry had been fixed for the 15th inst. It having been mentioned that the opponents to the scheme intended to be represented at the enquiry by counsel, it was resolved that the question of engaging counsel to represent the Town Council be left to Dr. Grey Edwards and the town clerk with power to act. A deputation from the Water and Gas Committee waited upon this committee respecting a small portion of the land recently obtained for the erection of a gasholder. After a short discussion, it was resolved that the committee, whilst looking favourably upon the application of the Water and Gas Committee, wish to consult their engineer before giving a definite reply. Major Cardew has held the enquiry in connection with the application of the Council for electric lighting powers. The objectors, who included the mayor, were represented by Mr. Griffiths, M.P. Among the witnesses for the Corporation were the Bishop of Bangor, Principal Reichel, Mr. E A. Young (representing Lord Penrhyn), and Messrs. Medhurst and Fawcus.

Coventry.—At the meeting of the City Council, the Electric Light Committee submitted two reports by their consulting engineer, Mr. Robert Hammond. Dealing first with capital expenditure, they stated that the £20 000 sanctioned had been exceeded by a sum estimated at £3,485. The bulk was accounted for by extensions of mains where the demand, actual or prospective, appeared to justify the expenditure, and by purchases of meters, stores, etc.—these accounted for £2,647. Turning to the future, the committee reminded the Council that the original outlay upon generating machinery was reduced to a minimum, while buildings and accessories were of ample size to admit of extension, which it was foreseen must soon become necessary. The additional capital thus expended was, of course, unproductive until generating machinery of corresponding power was installed. The fact that such was already necessary proved that the undertaking was making satisfactory progress. The units of current sold since January 1 were 10,650, which at 6d. per unit amounted to £266 5s. Meter rents and testing fees brought up the receipts to £275. 5s. The expenses for the same period, exclusive of interest and sinking fund, were £303. 8s. 2d. The number of lamps connected had steadily increased, and had the full number been connected from the first the consumption would have been considerably larger. The committee asked for two 30ft. by 8ft. Lancashire boilers, one 200-kilowatt alternator and engine to drive it, one pair high-tension feeding cables from the works, additional low-tension distributing cables, where necessary, additional transformers, with necessary extensions of boiler-house, switchboard, and economiser, steam and exhaust pipes, foundations accessories, and other adjuncts. The cost was estimated at £8,900. They recommended application for sanction to a loan of £13,000 to cover the increased cost of present works and proposed extensions. Alderman Hill, in moving the adoption of the report, said the experience of the electrical engineer was that Coventry had exceeded other towns in its desire to have this light. The lamps connected now numbered 3,612, and it was estimated that during the coming winter there would be between 2,000 and 3,000 more required, making altogether 6,000 lights. As to the generating plant it was proposed to put down, the 400-h.p. engine and the necessary parts connected therewith would cost £5,400, and the gas, transformers, and working would come to £3,500, making an expenditure of £8,900. Mr. West seconded, and remarked that commencing with nine customers and 458 lamps they had on January 1, 1,824 lampe; February 1, 2,299; March 1, 2,783; and April 1, 3,092; with 51 consumers. At the present time there were eight consumers waiting to be connected with 724 lamps, making a total of 3,816 lamps. The report was adopted.

Lambeth.—At the meeting of the Vestry the report of the special committee appointed to consider the proposals contained in the letters of the several applicants for the electric lighting order came up. The committee reported that after long and careful consideration they had resolved to recommend the Vestry to transfer its provisional order to Mr. C. W. Sax on the terms which we published in our last issue. The committee submitted the heads of the proposals by other applicants. Mr. Sydney Morse, on behalf of the County of London and Brush Electric Lighting Company, wrote stating that his company would lay down the mains in the compulsory streets within two years from the grant of the order, and would start with a charge of 7d. This,

Digitized by Google

he contended, would be cheaper than the terms quoted by Mr. Sax, which he interpreted to be a request by that gentleman that the Vestry should pay him £1,000 less than they now paid for dust disposal, and give him that which he stated would be a valuable fuel for the production of steam. He (Mr. Morse) hoped that before long the demand for electricity would enable them to reduce the price to 6d., but no company within the Metropolis had commenced to supply at a lower price than 7d., although the more successful companies had, by reason of the demand for electricity within their area, been able to make a reduction. Mr. Stewart Bain, on behalf of the London Electric Supply Corporation, wrote reminding the Vestry that they already held statutory powers under the Electric Lighting Acts in a part of the parish. They were perfectly able and willing to supply whatever demand for electric energy there might be in that part of the parish. He only regretted that notwithstanding the efforts that had been made to obtain business the demand was so scanty. The result of an exhaustive canvass in that part of the parish in which they had statutory powers during the last six years of reducing the price of the current from 7½d. to 6d. per Board of Trade unit, with a sliding scale of discounts to 5d., and 4d. per unit for motive power, and laying about 3,000 yards of distributing mains, was that they had obtained 27 customers. Under these circumstances he respectfully submitted that the Vestry should not at present give assent to any application which might be made by another company to that part of the parish in which they now had powers. He also submitted that it could not be for the advantage of the ratepayers in the district that additional competition should be introduced to that area. Mr. Chalton Hubbard asked whether it would not be necessary to rescind the resolution of the Vestry of September 5 before the report of the committee could be discussed. The Clerk (Mr. H. J. Smith) replied that he had looked carefully through the resolutions passed by the Vestry, and he found that in September the Vestry practically unanimously passed a resolution directing him to write to certain companies, intimating that while not in possession of sufficient information to justify any immediate action, the Vestry had no intention of surrendering the order. He did not think it would be safe to pass an important resolution of this kind transferring the order to any firm unless it were done at a special meeting called for that purpose. He suggested that the matter should stand over in order that a special meeting might be convened. It was unanimously agreed to adopt this course. The secretary of the Lambeth Ratepayers' Association wrote asking the Vestry to receive a deputation on the electric lighting question. There were requests for permission for other deputations, and all these were deferred to the adjourned meeting. Another meeting of ratepayers has been held to protest against the order being transferred. The following resolution was adopted with two dissentients: "That this meeting protests against the proposal of the Electric Lighting Committee of the Lambeth Vestry to hand over to a private individual the provisional order for electric lighting now held by the Vestry, by which action a most valuable asset would be lost to the ratepayers, and hereby asks the Vestry to at least fully enquire into the experience of other local boards in the matter, and also to fully consider the offer of the London Electric Supply Corporation to supply the current at the low price of 2¾d. per unit direct into the Vestry's own mains, by which offer the first cost of the supply would be very largely reduced, and would also enable the monopoly to be kept in the hands of the ratepayers, and thus avoid the payment of large compensation to some company in a few years' time."

PROVISIONAL PATENTS, 1896.

April 7.

7389. Improvements in telephone transmittors. Walter Louis Wilhelm and Byron John Tillman, 45, Southampton-buildings, Chancery-lane, London.

April 8.

7475. Improvements in electrical pilot or shallow water signals for vessels. Henry Harvey Franklin, 40, Chancery-lane, London. (Complete specification.)

April 9

7484. Improvements in electric meters Evershed and Vignoles Limited, and Sydney Evershed, Woodfield Works, Harrow-road, London.

7530. A new or improved electrical alarm apparatus. George Henry Atkinson, 37, Chancery-lane, London.

7556. Improvements in electric railways. Harry Clifton Reagan, jun., 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

7557. Improvements in commutator brushes and brush-holders. Robert Hirsch, Maria Rosamunde Hirsch, and James Franklin Trottman, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

April 10.

7588. Electric ram lift. Thomas Meacock, 18, Burlington chambers, New-street, Birmingham.

7621. Improvements in electric switches or apparatus for connecting electric circuits. Joseph Devonport Finney Andrews, 45, Fulham Park-gardens, London.

7622. Improvements in insulating materials and their application to electric wires. Joseph Devonport Finney Andrews, 45, Fulham Park-gardens, London.

April 11.

7649. Improvements in or connected with electric cables or conductors. Henry Edmunds, 47, Lincoln's-inn-fields, London.

7650. Improvements in wire ropes and armourings or coverings for electric cables. Henry Edmunds, 47, Lincoln's-inn-fields, London.

7668. Improvements appertaining to road vehicles propelled by steam, oil, electric, or like motor mechanism. Frank Lister, 56, Low-street, Keighley.

7694. Improvements in or connected with electric traction. Frederick Carleton Esmond, Norfolk House, Norfolk-street, London. (Date applied for under Patents, etc., Act 1883, Section 103, September 11 1895, being date of application in United States.)

7699. Improvements in lamp-posts or holders for electric street lamps and other large lamps. Josef Jakoubek, 433, Strand, London. (Complete specification.)

7716. An improved connection for electric light cables. Robert James Hatton and W. T. Henley's Telegraph Works Company, Limited, 53, Chancery-lane, London.

SPECIFICATIONS PUBLISHED

1895.

5451. Electric meters. Wright.

5892. Regulating electric currents. Hall and others.

NOTES.

Islington Central Station.—It may be worth noting that in the issue of April 19 of the *Elektrotechnischer Anzeiger* the first place is given to a description of the newly-erected generating station and works of the Islington Vestry.

Iron and Steel Institute.—For the forthcoming meeting of this institute to be held on May 7, a programme of 10 papers has been arranged. Members desiring to take part in the discussions can have them in advance on application to the secretary.

Liverpool Engineering Society.—The society have arranged visits to the Overhead Railway extension on May 16, and to the National Telephone Company's exchange on June 20.' There are also to be visits to Cambridge on July 3, and to Belfast on July 28.

The Electrophone.—It is stated that an electrophone has been installed in Marlborough House, and last Monday night the Princess of Wales and the Princesses Victoria and Maud were able to hear by its means part of the opera given at Drury Lane, and selections from the performances at other theatres.

Royal Institution.—The following appointments for forthcoming lectures at the Royal Institution are worth noting: Colonel Watkins, on "Chronographs," May 1; Prof. Silvanus Thompson, on "Electric Shadows," May 8; Mr. Alexander Siemens, on "The Amazon Cable," May 15; Prof. J. A. Ewing, on "Hysteresis," May 22; and Prof. J. A. Fleming, on "Electricity and Magnetism at Very Low Temperatures," on June 5.

Acetylene.—Some time ago we noted that the question of the production and use of acetylene appeared to be engaging considerable attention in the North of Italy, and we have now received the first number of *L'Acetilene*, a weekly illustrated review which is to be devoted to the subject. It is a small eight-paged paper published at Milan (Via Cairoli N. 2), and promises to contain contributions dealing with both the practical and scientific sides of the question.

Electrical Volunteers. — It is stated that Dr. Hopkinson's scheme for the establishment of a volunteer corps of electrical engineers has every chance of being carried out. The committee appointed to consider how the electrical engineers could best give their services as volunteers have sought the opinions of electrical engineers in all parts of Great Britain, and a large number of replies has been received expressing a desire to join any corps that may be formed. The committee are now awaiting the decision of the War Office, which it is understood will be favourable.

Stray Currents.—If the Chicago *Electrical Journal* is to be trusted, in St. Louis and other Western cities, people are running motors—no doubt small ones—and getting light from stray currents from the tramlines. The correct thing appears to be to make connections between water-pipes. The most curious part of the business is, however, that while the companies appear to consider themselves at liberty to corrode anybody's water-pipes by electrolysis, our contemporary seriously suggests that anyone utilising the stray current should be punished for "stealing electricity."

High-Voltage Lamps.—The "Review" in a recent issue of the *Elektrotechnische Zeitschrift* is devoted to the discussion at the Institution of Electrical Engineers on Mr. Addenbrooke's paper. The chief points are briefly summarised, and it is noticed, in conclusion, that when it is remembered that, as in a 220-volt installation, each 16-c.p. lamp will take at the most one-third of an ampere, an insulation rule based on 10,000,000 divided by the number of amperes supplied gives an insulation resistance 30 times greater than that prescribed by the safety rules of the Verband Deutscher Elektrotechniker.

Electric Fishery.—According to a note in the *Revista Tecnologico-Industrial*, a patent has been granted in Spain for the use of the electric light for fishing, and a company has been formed which will commence operations at Bilbao and other ports, either working on its own account or granting licenses for the use of its patent, and supplying the necessary apparatus to fishermen in return for a monthly payment. It is known that under certain circumstances a light will attract fishes, but beyond that it is difficult to guess in what way the electric light could be used, and unfortunately no details on the subject are given by our contemporary.

Forcing Plants by Electricity.—The professors in the department of horticulture at Cornell have just concluded important experiments in developing plants by electric light. Prof. Bailey said: "We are highly gratified with the result. We have proved that by using electric light during the daytime we can produce lilies fully two weeks before those that are grown under natural conditions. The effect is fully as marked in the case of lettuce, but we found that electricity is a positive detriment to peas. We will still continue our investigation on different plants, and will ascertain the effects on vegetation of the Röntgen rays. We shall also experiment on plants by electrifying the atmosphere in which they are grown."

The Telephone Service.—At the monthly meeting of the Cardiff Chamber of Commerce on Wednesday there was a resolution proposed by Mr. J. Andrews: "That in the opinion of this Chamber it is urgently necessary that subscribers to the telephone systems of the Post Office and the National Telephone Company in the same local area should be enabled to communicate directly with each other in the same way as can now be done between different areas, and that representations to this end be made by the Chamber to the Postmaster-General and the National Telephone Company." It was, however, decided to urge the Government to buy up the company's system altogether. In reference to the extension of the trunk lines, the Postmaster-General has informed Mr. Gordon, M.P., that he will recommend the erection of a trunk telephone circuit from Aberdeen to Elgin and Inverness.

Crystal Palace Engineering School.—In distributing the certificates to students attending the lectures and classes at the Crystal Palace Company's School of Practical Engineering last Friday, Mr. A. T. Walmisley, M.I.C.E., engineer of the Dover Harbour Board, said that very few people were acquainted with the great amount of educational work carried on at the Crystal Palace. The engineering classes began in 1872 with 15 students, and since that time there had been as many as 100 during the year under instruction. The number at present was 71. That the school had done thoroughly good work was shown by the positions which former students now occupied in various parts of the world. Mr. Rait, the chairman of the Crystal Palace Company, in thanking Mr. Walmisley on behalf of the directors for his address, said that the Crystal Palace in educational, as in other matters, had kept pace with the times.

Corporations and Tramways.—It has been generally believed that Belfast intended to go in for electric tramways, but it is, however, to be feared that the prospects of electric traction there are not nearly so favourable as many have hoped. From what we have

Digitized by Google

been able to ascertain, the conditions laid down by the Corporation are of practically an impossible nature, and the entire question is therefore likely to be shelved for the time being. It is understood that, not contented with the safeguard of the Board of Trade rules, the Corporation insist on making the tramway company responsible for all damage to gas and water pipes it is supposed to be caused by electrolysis. On the face of it this does not seem unreasonable, but the clauses would almost certainly be construed so as to cover an amount of ordinary deterioration with which electrolysis has nothing to do. After the Board of Trade has prescribed rules which, according to the best opinions obtainable on the subject, will prevent a thing happening, it is a little unreasonable for a body of non-experts to straightway assume that it is going to take place.

The Steam-Boilers Bill.—A deputation chiefly representative of "labour" interests has waited upon the Home Secretary to ask him to use his influence in pressing forward the Engines and Boilers (Persons in Charge) Bill before the House of Commons. It will be remembered that this Bill got as far as the Grand Committee stage some years ago, but the amendments necessary to make it reasonably workable were such that it had to be withdrawn. On the present occasion Mr. Fenwick stated that the deputation asked that persons in charge of engines and boilers should be forced to satisfy a board of examiners before taking charge of such machinery. The Home Secretary, in reply, said he still required to be convinced that, apart from collieries, such an examination as was suggested would afford any more adequate guarantee against accident than they at present enjoyed. Before the Bill came on in Parliament he would give it his best consideration, but he was not particularly sanguine nor convinced of the necessity for the Bill. Should the attempt to revive this Bill prove serious, it is a matter which will deserve attention on the part of central-station engineers.

The Amazon Cable.—The cable up the River Amazon has been laid and is in a completely satisfactory condition, and the s.s. "Faraday" returned last week to the Victoria Docks after a thoroughly successful expedition. A full account of the laying of the cable, of the obstacles met with, and how they were overcome, is to be given by Mr. Alexander Siemens in a lecture at the Royal Institution on May 15. We have Mr. Siemens's authority for stating that the health of the staff during the expedition was good, and although a few cases of fever occurred the excellent arrangements on the "Faraday" and the other ships employed enabled those cases to be successfully dealt with. For an expedition carried out in so unhealthy a climate in the wet season, this fact alone speaks highly for the organisation of the work. It is interesting to note that besides the cable staff room was made on the "Faraday" for two representatives of the British Museum, so that advantage might be taken of the opportunity which the expedition offered of making an interesting series of investigations into the natural history of the Amazon basin, and it is stated that these gentlemen have brought home a large collection of specimens illustrating the fauna of the primeval forests on the banks of the Amazon.

Electrical Standards.—In the House of Commons on Tuesday, Colonel Mellor, the member for Radcliffe, asked the President of the Board of Trade whether the Board could offer the same facilities for testing and checking electrical standards as are given by the German Government with so much advantage to the German manufacturers of electrical apparatus. Mr. Ritchie, in reply, said the Board of Trade had caused new denominations of standards for the measurement of electricity to be made and verified, and they now had under consideration the best method of affording facilities to manufacturers and others for comparing their instruments with those standards. In reference to this the *Times* remarks that "official tests of electrical standards have not hitherto been made in this country, with the result that British manufacturers requiring certified instruments have been compelled to procure either German goods or English goods certified in Germany. Most purchasers have adopted the former alternative as being both cheaper and less troublesome." It is added that what Colonel Mellor desires is the establishment in England, under the authority of the Board of Trade, of a department similar to that of the Physikalische Reichsanstalt of Berlin, where for a few shillings the finest tests may be applied to electrical resistance standards and all other descriptions of electrical apparatus. The new departure contemplated by the Board of Trade will go a long way in the direction indicated.

City and Guilds Examinations.—The examiners report as follows on the papers sent in last May in the subject entitled "Electric Lighting and Power": "The answers in the preliminary examination show a much higher level of attainment than last year, but candidates generally appear to be very ill-informed about arrangements of circuits. The answering in the ordinary grade is very unequal. The occurrence of batches of consecutive papers with answers of an unpractical or ill-informed kind shows that in a number of cases the classes are being conducted by teachers who are not really electrical engineers, and have no real knowledge of the subject. The sketching generally is poor. In the honours grade, Division I. (electrical instrument making), candidates generally are weak in ability to apply calculations to the problems of instrument design. In Division II. (dynamos and motors) the answers are decidedly poor. Many of the candidates have evidently no knowledge of engineering or of engineers' drawing. It ought to be understood that this branch dealing essentially with the constructive part of electric machinery, the questions will be such as require a certain amount of mechanical knowledge, and especially of engineering drawing. Candidates will be expected to be able to indicate by sketches (sections, etc.), marked with dimensions, what they know of dynamo and motor construction, etc. In Division III. (central-station work, etc.) the answers are more numerous than before, and show a sound acquaintance with the subject. Several papers were really excellent."

Chemistry and the Arc.—Prof. Dewar has been lecturing at the Royal Institution on "Recent Chemical Progress," and evidently considers that the electric arc has had its share in it, and will have a greater one in the future, more especially in the synthetic formation of compounds. Some most interesting results had been obtained, he said, from the electric furnace by the French chemist, Mr. Moissan, in the shape of carbides, stable bodies produced by the combination at high temperatures of carbon with various metals. Many of these carbides were decomposed by water, the hydrogen of the water combining with the carbon to form hydrocarbons. Thus with water, some carbides, such as that of calcium, gave acetylene; others like that of aluminium, gave marsh gas, while others, again, gave these and other gases, and, what was most wonderful, liquid petroleums. It was a curious fact that many years ago Prof. Mendeleief speculated that the only reason for the immense localisation of petroleum at Baku was that it was being generated there—he suggested by the action of water on carbides. His idea was rather smiled at then, but now it was his turn to smile. When acetylene was heated to a dull red heat, it was polymerised to benzene. Benzene was the basis of all the new modern colours, and

Digitized by Google

thus by three direct stages it was possible to reach the nucleus of all the colours hitherto manufactured from coal-tar products. First, there was the combination of lime and coke in the electric furnace; second, the decomposition of the carbide thus formed by water; and third, the transformation into benzene of the resulting acetylene by means of heat.

Motorcarts.—The proprietors of the *Engineer* have published the conditions of their 1,100 guineas motor carriage competition, and the Crystal Palace Company will give facilities at the palace for showing the carriages in work there, and for holding the subsidiary trials. The judges will be Sir Frederick Bramwell, F.R.S., M.I.C.E.; Mr. J. A. F. Aspinall, M.I.C.E., chief mechanical engineer to the Lancashire and Yorkshire Railway; and Dr. John Hopkinson, F.R.S., M.I.C.E. The competition is to be international. The vehicles will be divided into four classes, according as they are to carry four or two persons or to convey light or heavy goods, with a supplemental class for an oil-motor car. With the exception of this class any method of propulsion other than muscular power may be employed, provided it be contained in the vehicle. Preliminary runs in the grounds of the Crystal Palace will be made with each of the vehicles in succession by the competitors in the presence of the judges or of someone representing them. The practical working run will consist of a run on the public roads of not less than 100 miles out and 100 miles home, or a total of not less than 200 miles over a course to be announced three days prior to that fixed for the run. It will probably be arranged for Monday, October 12. Any vehicle which does not complete the "practical working run" at a minimum average speed of five miles an hour, to include all stoppages, will be disqualified. The British Motor Syndicate, Limited, has held its first ordinary meeting, and declared a 10 per cent. dividend. At Belfast, the Lord Mayor has presided over a meeting in support of Lord Harris's Act. The London Chamber of Commerce will discuss the subject to-day (Friday).

Institution of Civil Engineers.—In the paper read by Mr. N. G. Gedye on "Recent Developments in Lighthouse Engineering," at the Institution of Civil Engineers, it was pointed out that a marked development had of late years taken place in the direction of reducing the length of flash emitted by lighthouse apparatus to a minimum, and a consequent increase had been obtained in intensity. But in this country the Trinity House Corporation still adhered to the old-established system of long duration of flash, although two sets of apparatus are about to be established at Lundy Island, in the Bristol Channel, revolving over mercury floats, and giving flashes of very short duration. The apparatus now being erected at Cape Leeuwin, Western Australia, gave a flash of one-fifth second duration every five seconds. The apparatus was designed by Mr. W. T. Douglass, M.I.C.E., of Westminster, for the Government of Western Australia, and was an oil light. The powers of oil lights, however, were far exceeded by electric lighthouse lights, there being several of these in France up to 23,000,000 c.p., while there has recently been established at Fire Island, at the entrance to New York Harbour, an electric light of French design and construction of 123,000,000 c.p. This was the most powerful lighthouse light in the world. The old roller-revolving carriages hitherto used for lighthouse apparatus had now been superseded in the case of quick-flashing lights by the ingenious and beautiful arrangement of mercury flotation invented by Mr. Bourdelles, of the French lighthouse service. The whole revolving portion of the apparatus, weighing in the case of Cape Leeuwin nearly three tons, is floated and revolved in a bath of mercury, thus reducing the friction to a minimum. Although the powers of electric lights might be increased to an even greater extent than at present, yet, after all, no light—electric, gas, or oil—was of any use in a fog when that fog had developed into anything denser than a mist. The paper was illustrated by numerous models and diagrams.

Rontgen Radiations.—The strong point of the Americans is practical work rather than scientific theory, and therefore any very serious contribution to an explanation of the Röntgen radiations is hardly likely to come from the other side of the Atlantic. The Franklin Institute, however, has been discussing the subject, starting from a paper by Dr. Houston and Dr. Kennelly, which was mainly a *résumé* of what is known in the matter. The subject is one upon which the merely practical man, if he is wise, holds his tongue. There was, however, on this occasion a considerable number of communications from professors and others. Prof. Elihu Thomson thought the new radiations were extreme ultra-violet waves. Prof. Dolbear and Dr. J. Richards, on the other hand, considered them to be below the infra-red, and Prof. C. F. Himes and Mr. J. Wilson, on the whole, agreed with this, and so did Prof. Snyder. Mr. Outerbridge, jun., advocated the longitudinal hypothesis. If, in America, they favour the infra-red solution, in France, where the theory of light is more studied, the general drift of opinion seems to be in favour of an extreme ultra-violet wave. Mr. C. Henry has advocated this in a paper presented to the Paris Académie des Sciences. When doctors differ, who shall decide? Obviously the competent experimentalist. But until he does so the ultra-violet hypothesis stands the better chance, since there is no limit to the smallness of the wave in that direction, while the advocates of an infra-red theory have to do all their work within known bounds. Although the longitudinal hypothesis no longer occupies the place it did, it is, to say the least, curious that the objection has not been more prominently urged, that if such vibrations are possible in air they must be generated and transmitted in a great many other ways than by a Röntgen tube. When it is attempted to deal with the hypothesis quantitatively, this will bring it into even narrower limits than the preceding one. Only in this case it will be the energy carried, and not the wave length, that is limited.

The Telephone Monopoly.—Mr. J. Henniker Heaton has written to the *Times* on the subject of the bargain between the Post Office and the Telephone Company. "It will be remembered," he says, "that this contract was modestly withheld from an inquisitive House of Commons until it was sealed, signed, and delivered. Then it appeared that the companies were to have a monopoly of telephonic business in the towns for many years to come, while the Post Office was to enjoy the business on the trunk lines between town and town. In other words, to the companies was assigned the oyster and to the public (represented by the Post Office) the shell." The Post Office authorities have provided that in 1911 they should have the right to buy up the companies, but Mr. Henniker Heaton thinks when they come to do it the taxpayer will wear a ghastly smile. "I wonder," he adds, "if they have ever made a rough calculation of what the purchase-money (under the contract) will amount to. I put it at a hundred millions sterling, more or less. Possibly Chancellors of the Exchequer will be a bolder race in the next century. But it may be doubted whether one will be found hardy enough to propose the raising of such a sum (10 times more than we paid for the telegraphs) for any such purpose." Instead of being content to glean after the companies and wait while

Digitized by Google

"interests" and "unearned increments" are manufactured, Mr. Henniker Heaton urges that if the Government is really in earnest, and intends to acquire and work the telephones on behalf of the public, it is high time for them to set about the scheme in a businesslike way, without a day's hesitation. "I would therefore suggest," he concludes, "that such members as agree with the views above expressed should communicate with me for the purpose of impressing on Ministers the urgent necessity of dealing with this burning question. Several Ministers are believed to regard the situation with grave apprehension, and doubtless all would be glad to have their hands strengthened by a definite expression of public opinion."

Colour Photography. — There was a very large attendance at Mr. Gabriel Lippmann's lecture on "Colour Photography" at the Royal Institution last Friday. Among the audience were Lord Kelvin, Sir G. Stokes, Sir Frederick Abel, Sir James Crichton Browne, Sir Benjamin Baker, Prof. Dewar, and Dr. Frankland. Mr. Lippmann said of the problem of colour photography, which was as old as photography itself, three distinct solutions had been attempted. In 1840 E. Becquerel converted the surface of a daguerrotype plate into the violet subchloride of silver, and by projecting on it the image of the solar spectrum and other objects obtained coloured impressions. The image, however, was not fixed in the photographic sense of the word, but was blotted out if the plate was exposed to daylight. The second method for colour photography might be called the three-colour method. It could give a very good approximation to the truth, and probably had a great future before it. It was an indirect method, because the colours were not generated by the action of light, but were supplied subsequently by the application of aniline dyes or other pigments. The third and latest was the interference method, which he first published in 1891, and the latest results of which he was bringing forward. For obtaining coloured photographs by this method only two conditions had to be fulfilled. There was wanted, first, a transparent, grainless, photographic film of any kind capable of giving a colourless fixed image by the usual means; and, second, a metallic mirror placed in immediate contact with the film during the time of exposure. A mirror was easily formed by means of mercury. The incident and reflected undulations concurring produced stationary waves, so that it resulted that, whereas in the case of an ordinary photograph the deposit would simply be a formless cloud of metallic particles, in a colour photograph the cloud had a definite stratified form; it was divided into a number of equidistant strata parallel to the surface of the plate and $\frac{2}{10000}$th of a millimetre apart. These being at the proper distance for reflecting the incident colour rays only reflected that colour. A number of photographs taken by this method were exhibited, in which the colours of stained glass and of natural objects, such as flowers and trees, were reproduced.

Incandescent Gaslight. — The Incandescent Gaslight Company, Limited, obtained judgment in Mr. Justice Wills's court on Saturday last against the De Mare Incandescent Gaslight System, Limited, for infringement of the Welsbach patent of 1885. At the same time judgment was given in the action brought against the Sunlight Incandescent Gas Lamp Company, Limited, but in this case Mr. Justice Wills held that the Dellwik patent, which the defendant company proposed to work, was essentially different from what was claimed by the Welsbach specification. He felt that the defendants were taking a very valuable process bodily from Welsbach without any remuneration; but that was the necessary fate of a patentee who confined himself to claiming the aggregate of a whole string of processes. He therefore gave judgment for the defendants upon the issue of infringement. He, however, found for the plaintiffs as to the validity of their patent and reserved the question of costs. As it is practically certain that both decisions will be appealed against, this may be regarded as little more than the first stage of the matter. In connection with this case the *Times* makes some remarks which are equally appropriate to other patent suits: "Dr. Welsbach is not the first, and will not be the last, pioneer to find that others quietly enter into his labours. One reflection is likely to occur to any who has watched the progress of these cases. The substantial question to be determined was one of chemistry and chemical history. The principle of law to be applied was clear and simple. A cloud of scientific witnesses was in attendance, and men of great eminence, such as Sir Henry Roscoe and Prof. Dewar, were called on both sides. The objection to this course is not perhaps very serious when the litigants are wealthy companies and the patent is of great value. But it must strike any impartial mind that the length of such enquiries would be curtailed, that the expert would be more in his true place than he often now is, and that there would be fewer exhibitions of startling conflicts between the opinions of high scientific authorities, if the Court frequently did what it is not customary to do—namely, took the evidence more into its own hands, nominating one expert, or it may be two, to report for its guidance on some of the matters of controversy. An expert reporting as the delegate of the Court would sometimes express himself very differently from one paid for his evidence, and many cases would occupy as many hours as they now occupy days."

The Metric System.—As a sequel to the *Times* articles there has been further correspondence on the subject of the adoption of the metric system, including letters from Mr. G. Johnstone Stoney and Sir Frederick Bramwell. The position taken up by the latter is as follows: "I do not wish to impose English weights and measures and the employment of vulgar fractions on the community. I would make the metric decimal system legal for all purposes, but I would leave everyone at liberty to use that which he preferred." But the practical interest has been taken out of the controversy by what has passed in the House of Commons, where, on Monday, Mr. Arnold-Forster (Belfast, W.) asked the First Lord of the Treasury whether, in view of the fact that the metric system of weights and measures had recently been adopted by Turkey, Russia, and Japan, and was now in use in all the civilised countries in the world with the exception of the British Empire and the United States of America, and in view of the fact that metric measurements had already been adopted with respect to the ton and for all purposes of pharmaceutical dispensing in the United States, her Majesty's Government would take immediate steps to give effect to the practically unanimous recommendation of the Committee on the Metric System, with the object of placing this country on a level with other civilised nations in the matter of weights and measures. To which Mr. Arthur J. Balfour replied: "In answer to my hon. friend, I have to say that the recital of facts in his question is, I believe, correct; but I do not think it would be within the range of practical politics to impose by law on the inhabitants of this country so great a change in their ordinary habits as would be involved in giving effect to the recommendation of the Committee on the Metric System." Mr. Arnold-Forster, however, was not going to allow the subject to drop thus easily and proceeded to ask Mr. Balfour whether he was aware that a Bill for this purpose

Digitized by Google

had been introduced into the House of Representatives of the United States, and whether, on behalf of the Government, he would support an amendment of the Standing Orders of the House by which the use of weights and measures of the metric system might be permitted in the case of plans, specifications, etc, submitted to Private Bill Committees? The reply to this was that the American Bill was not passed yet. At present the metric system was illegal in this country, but when the restrictions imposed upon its use were removed it would follow, as a matter of course, that the Standing Orders would have to be altered also. Mr. Gibson Bowles said that contracts could now be legally made in the metric system, but Mr. Balfour thought not, but promised to make enquiry. From this it would appear that nothing more serious is likely to come at present of the committee's report than a "permissive use," in which case it will be a long time before we get a rational system of weights and measures, either decimal or other.

City and Guilds of London Institute.—The report of the council upon the work of the institute for the year 1895, adopted at Wednesday's meeting, reminds us of the loss the institute has sustained in the death of their late chairman, the Earl of Selborne, who from as far back as 1876 took a prominent part in all matters connected with technical education, and who occupied the chairmanship of the institution from its foundation in 1878 up to the time of his death. Dealing first with the report of the Central Institution, it may be noticed that at the close of last session the diploma of associate of the City Guilds Institute (A.C.G.I.) was granted by the council to 37 students who had matriculated and followed one of the three courses as prescribed in the programme of the college—12 in civil and mechanical engineering, 19 in physics and electrical engineering, and six in chemistry. Of the same number of associates who were elected in 1894 it seems that 28 have taken to practical work, and several already hold good positions where the technical training will be of great service to them. The report continues: "The twelfth complete session of the day department of the Technical College, Finsbury, ended in July last, with 210 students in attendance, as against 197 in the previous session, and it is satisfactory to note that this increase has shown itself in the mechanical and chemical departments rather than in the electrical department; for, although the electrical industries of the country have rapidly increased during the past few years, and have consequently opened out a good field of employment for well-trained youths, yet there have not been wanting signs that the market would soon become overcrowded, and that the rush of students desirous of qualifying for employment in electrical works would be checked." The reports on the technological examinations show that the total number attending classes in all subjects was 27,583, an increase of over 2,200 on the previous year. The proportion of candidates who succeed in passing the examinations of the Science and Art Department, and of thus qualifying for the full technological certificate, is still very small; and accordingly the institute has decided to accept its own preliminary examinations in certain subjects, as being better adapted to the requirements of artisans, in lieu of those of the Science and Art Department. It is hoped that this regulation will increase the number of candidates qualifying for the full certificate. One effect of the addition of the preliminary examinations has been to increase the proportion of passes in the ordinary grade of those subjects in which these examinations have been held. The whole report shows that most useful work is being done, and the council of the institute are to be congratulated on the success attending their efforts. Lord Halsbury presided at the annual meeting on Wednesday, when, besides the report mentioned above, there was a proposition from the Mercers' Company for a committee to investigate the expenditure of the funds, the idea being that not enough was done for "those on the lower steps of the ladder." As the requisite notice had not been given with respect to the resolution of the Mercers' Company it was ruled not in order, but the chairman said it could be discussed at a special meeting.

Polyphase in America. — Writing on "Central-Station Working" in the New York *Electrical World*, Mr. H. E. Raymond remarks that in the past four years there have been quite a number of power transmission plants installed in the United States. In these the current used is polyphase alternating, and the voltage employed varies from 2,200 to 3,000 volts. The length of the line varies from three to ten miles. In the installation of such systems, under these conditions, very few "line effects" were anticipated, it being thought that static capacity and possibly resonance would be experienced only on lines of considerably greater length and with the use of a much higher voltage. Practice, however, has shown these effects to be noticeable in systems in which synchronous motors constitute the main portion of the load. In one synchronous motor system, which extends over a distance of but four miles and employs a voltage of 2,500 volts, the static or capacity phenomena were so marked as to be the cause of considerable trouble. This effect was first noticeable in connection with fuse blocks of the magazine principle. These blocks consisted of two fuses in multiple, one being opened about $\frac{1}{4}$in. by means of a thumbscrew. When from any cause the first fuse blew, the current would invariably jump the gap and run on the other fuse. Though quite convenient as an automatic shifting device, it is hardly necessary to state that the life of the fuse block was prematurely short. At each end of the system there was, on each wire, a lightning arrester with a total gap to ground of $\frac{3}{8}$in. At times when the lines were being tested for grounds, a small arc would form from the line through the arrester to the ground, the current returning through the ground detector. If any grounds were in existence on the line the arc in the arrester would, of course, be much more intense. At the same time the current would jump from the ring terminals to the shaft, or from the brush-holder studs through or around the rubber washers to the frame of the machines. This discharge to the ground and frame of the machine nearly always took place at the motor end of the system. During any sultry day in summer there was a likelihood of a discharge taking place through the arresters, and as these were entirely incapable of rupturing the succeeding arc, the arrester was generally repaired by putting up a new one and burying the old. The remedy for most of these troublesome phenomena was the use of what are called "tank" arresters. These have been so arranged that they can be left in connection or cut out at any time, cleaned, and repaired. They are arranged one to each wire entering the station, and if one or two be thrown in and the switch on the other nearly closed, a spark will jump the open space of $\frac{1}{4}$in. to $\frac{3}{8}$in. and continue to do so steadily, showing the continual accumulative charge. Beside using these tanks, marble or rubber guards have been inserted between all exposed points of different potential in order to minimise the danger from current arcing from one to the other. Mr. Raymond adds that in many stations one thing which is the cause of more trouble in alternations of high potential than everything else combined is neglect of cleanliness, and it is surprising how little attention is paid to this important point.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE XXVIII.

(Specially Contributed.)

Before leaving this historic part of the subject, there is one other experiment described by Faraday in his lecture which may be referred to. He took a coil of wire (Fig. 1), connecting its two ends to the terminals of a galvanometer. He then took "a cylindrical magnet ¾in. in diameter and 8½in. in length." . . . . . "One end of this magnet was introduced into the axis of the helix, and then, the galvanometer needle being stationary, the magnet was suddenly thrust in; immediately the needle was deflected. . . . Being left in, the needle resumed its first position, and then, the magnet being withdrawn, the needle was deflected in the opposite direction"

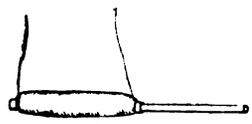

FIG. 1.

A more complete illustration of this apparatus is shown in Fig. 2. If the permanent magnet be rapidly thrust into the coil, we get a deflection of the needle. If the magnet remains in, the needle returns to its point of rest, and on withdrawing it we get a deflection in the opposite direction to that which occurred on its insertion; or if we pass the magnet right through the coil as it leaves the end opposite to that by which it entered, we get a reverse deflection.

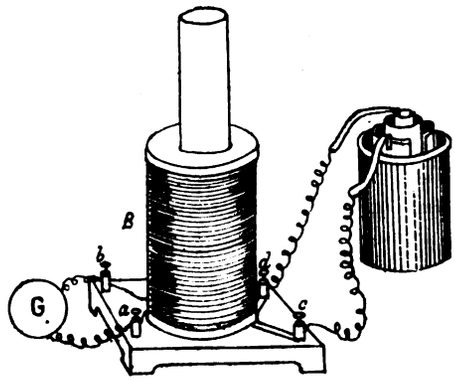

FIG. 2.

More About Lines of Force.—We have seen that all magnets or conductors carrying current exert an influence over the air-space immediately surrounding the magnet or the conductor. The air-space over which a magnet exerts this influence is called its magnetic field. The strength of the magnetic field at any one point depends, so to speak, on the quantity of this influence. Now, we can conventionally agree to measure quantity of influence in one of several ways. That which has been chosen, and is well adapted for the purpose, is the convention of lines through a given area. If we have an area of a square inch at any point, and we suppose *one* line passes through this area while *ten* lines pass through a square inch at some other point, we can compare whatever it is agreed that lines should measure at these points. At one place, whatever is to be measured is 10 times greater than at the other. Now, if a piece of soft iron be placed in a magnetic field, it passes or tends to pass from the point where the influence is weakest to the point where it is strongest—that is, there seems to be a force pulling it in a certain direction, hence we have agreed to measure the amount of magnetic influence by lines, called lines of force. The soft iron would have exerted upon it 10 times the influence when the number of lines of force were 10 to the square inch than it would when the number was but one to the square inch.

Closed Curves.—The direction of the magnetic influence, and therefore of the lines of force that represent that influence, is always to return upon itself; hence each line of force forms a closed curve. As might be expected, the magnetic influence follows the line of least resistance. If the field is in an homogeneous medium, then it may be represented by a number of lines each taking the shortest path left open to it through the medium. No two lines can take the same path. Not only do we conventionally represent the field by lines, and the density of the field at any point by the number of lines per unit area at that point, but we also agree to assume the magnetic influence, flow, or flux, or whatever we like to call it, leaves the permanent or the electro-magnet by the north pole and enters by the south pole. Let us once more examine the lines of force from a bar magnet (Fig. 3). Just at the centre of the magnet the lines do not leave the magnet, but commence to leave just past the centre, and, as shown by the filings, curve round to enter at a distance on the other side of the centre equal to

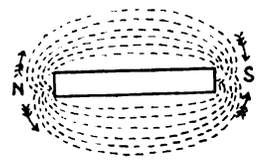

FIG. 3.

that on the side by which they escaped. The greater number of lines seem to leave the magnet near to the N pole and enter it near to the S pole. The whole of the lines pass through the centre of the magnet, hence it is of uniform dimension; the density of the lines at the centre in the magnet must be greater than at any other point—that is, the greatest magnetic strength is just where we in this way see it least. If we take any section through the field the same number of lines pass through that section as through any other section, and will be twice the number of lines through a section of the magnet at its centre. If we assume that magnetic lines of force are, in magnetism, the analogues of current in electrical circuits, we know in the latter case that the same current flows through each point of the circuit. The interior of the magnet may be looked upon as similar to the interior of the battery. The air-space occupied by the field is similar to the external circuit of the battery. The sectional area of the magnetic field differs, however, from that of a conducting wire. The latter is generally fairly uniform at all points, while the former differs considerably at every point. I refer to the sectional area of the external magnetic field—it is smallest near the poles and largest through the point midway between the poles. Roughly speaking, the field of a cylindrical bar magnet must be, when placed in the air, very much the shape of a Rugby football.

Similar quantities have to be dealt with in magnetism as are dealt with in electricity, and a law similar to Ohm's holds good in the one as in the other. We have symbolised the magnetic law thus—

$$L = \frac{P}{R};$$

where L = number of lines of force;
„ P = magneto-motive force (pressure);
„ R = resistance.

Analysis of Pixii's Machine.—The starting point of Pixii's machine for our purpose is the permanent horse-shoe magnet. We may represent this and its lines of force as in Fig. 4. Faraday had just shown that if the lines of force of a magnet were linked or looped around a conducting coil, there would be a current generated in that coil. Pixii, in the first place, provided a less resistance than the air-space for the external lines of force. No doubt he did not see the matter in the same light as we do, and only looked upon his soft-iron core as something upon which to coil his conductor, but his core did nevertheless offer an easier path to the lines of force, and with it our Fig. 4 becomes as Fig. 5, almost all the lines of force going through the soft-iron core, C C. It does not matter whether the core is shaped one way or another, as in Fig. 6, with two arms, C C, and a yoke, Y. Placing a coil upon one or both arms of the core gives us the means of linking or looping the lines of force of the magnet around

Digitized by Google

the conductor. One coil of conductor with the lines looped round it would give a certain effect on the galvanometer, two coils would double the effect, three coils treble it, and *n* coils increase it *n*-fold. If we put the same number of coils on each arm we shall find the effect of each set upon similar galvanometers is alike, and joining up the two sets so as to form one continuous set would double the effect upon one galvanometer. So long as you loop the same number of lines around similar coils you get similar results. Suppose N represents

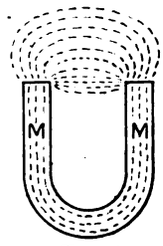

FIG. 4.

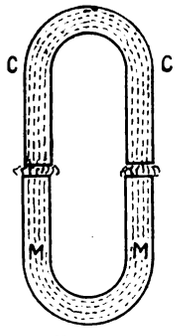

FIG. 5.

the north pole of the permanent magnet from which the lines go through the air-space to the core of the coil through the core and the other air-space to S, the south pole. If we turn the permanent magnet through half a revolution, the N pole will then be under the opposite arm of the core to which it was at first (Fig. 7)—the direction of the magnetic lines will be reversed, and the current in the coil will be reversed. Thus, you will see the current in the coil is reversed twice in each revolution of the magnet—it is alternated. Hence, we call such a machine, not only a magneto-electric machine, because the field magnet, or the magnet producing the field, is a permanent magnet, but an alternating-current machine, because of these periodic reversals of the direction of the current.

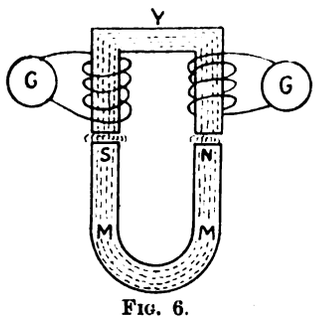

FIG. 6.

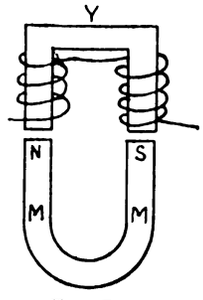

FIG. 7.

The lines of force have another similarity to a current of electricity. We have seen that if a current has the choice of two or more paths, it divides itself inversely as the resistance of the paths; so do the lines of force. Having in this apparatus a path of comparatively small resistance when the poles of the revolving magnet are opposite the poles of the coils, we shall see that this path increases in resistance as the poles are revolved to a maximum when a quarter turn has been made, then decreases again to a minimum when the half-turn is finished. Suppose the magnet to be of very small sectional area, its poles to be represented by the points, S N (Fig. 8). Similarly, the

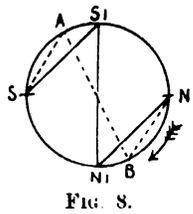

FIG. 8.

opposing core poles may be supposed to be very small, and very close to the magnet poles, so that S N (Fig. 8) may also represent their position. The magnet poles as they revolve describe a circle so that their position at any point during the revolution can be indicated upon the circle described. Suppose now (Fig. 8) the magnet rotated through a quarter of a revolution, the position of its poles may be represented by S_1 N_1 and the distance between S_1 N_1 represents the distance of the air-space between the poles.

Consider two paths only for the lines of force, though in reality there are others, the consideration of which, however, would complicate matters:

1. The direct path from N_1 to S_1.
2. The path from N_1 through air space N_1 S to the end of core just left by N through the core to the end of core at S just left by S and air-space S S_1.

The direct air-space path, N_1 S_1, is always the same, and therefore may be taken to always have the same resistance.

The second air-space path increases as the poles move from the position N S, and is at its maximum when the poles are at N_1 S_1. This path may be represented by the *sum* of the chords $S S_1 + N N_1$. There are two positions in the whole revolution where the two paths have the same length—and therefore presumably the same resistance—and hence when an equal number of lines of force go by each path. Take a pair of compasses, and with distances the radius of the circle from S cut off parts S A_1 and S A, from N cut off N B_1 N B. In the rotation, when pole N has moved to B, then pole S will be at A, and chords N B + S A = diameter = S_1 N_1. Again, when S is at B_1, N will be at A_1, and again sum of chords N B_1 + S A_1 = diameter = S_1 N_1. In these two positions, then, an equal number of lines of force should go by each path. An examination of the diagram will show you how the air-space when measured from the poles to the ends of the core of the armature varies throughout the armature. Of course the total air-space of this circuit is always the sum of two air-spaces. Now, air is a very bad conductor of lines of force; in fact, for all practical purposes, there is only one good conductor—that is, iron. Even iron varies considerably as a conductor of magnetic lines of force. The best Swedish soft iron is perhaps the best conductor of lines of force that can be obtained.

Pixii's machine, then, dealing as it did with so much air-space, was far from being an efficient machine.

Aim of Electric Generators.—The aim of the various electric generators, whether batteries, magneto machines, dynamo machines, or thermo-electric machines, is to transform some other kind of energy into electric energy. In batteries, chemical energy is so transformed; in magneto and dynamo machines, mechanical energy derived from heat energy is transformed; and in thermo-electric machines, heat energy is transformed.

DYNAMO PLANT FOR TELEGRAPHIC PURPOSES.*

The Western Union Telegraph Company has installed in the basement of the Western Union Building a remarkably flexible and complete system of dynamos for supplying current to the numerous lines radiating from its office. The plant consists of three main batteries of dynamos, 19 of which are Edison No. 2 machines of a rated capacity of 110 volts and 40 amperes; two Crocker-Wheeler generators of the same capacity are also used, being machines No. 1 in the positive and negative gangs (see Fig. 1). In addition are used 25 Crocker-Wheeler $\frac{1}{3}$-h.p. 85-volt generators, the use of which will be subsequently referred to. Three New York safety engines of 20 h.p. each furnish the motive power, and in case of accidents, Sprague motors, deriving current from the mains of the Chicago Edison Company, can be instantly substituted for steam power. Two of these motors are of 15 h.p. each, the other one being rated at 10 h.p. Fig. 1 shows the general arrangement of the plant. The positive and negative gangs each consist of eight generators and the spare gang of five machines. The positive gang may, however, be run as the negative gang and *vice versâ*, while the spare gang can be used either positively or negatively, and these interchanges are made daily.

With the positive and negative gangs in operation the first three machines on one side only are used. Taking the

* From the *Electrical Journal* (Chicago).

Digitized by Google

machines in their numerical order, No. 1, of 45 volts potential, is used to supply all pony wires within the city limits; No. 2, seven volts, is used entirely in the office for energising single-wire sounders; No. 3, 23 volts, energises the sounders of all multiplex instruments; Nos. 4, 5, 6, 7, and 8 are connected up almost on the principle of the Siemens and Halske multi-wire system, except that one side of the system is grounded (Fig. 2). These five machines, which are duplicated by the five in the spare gang, must be run in sets of two, positive and negative. Nos. 4 and 5 are used to work single and multiplex circuits for short distances. Nos. 6, 7, and 8 are used entirely for multiplex circuits, the voltage increasing with the distance and the resistance.

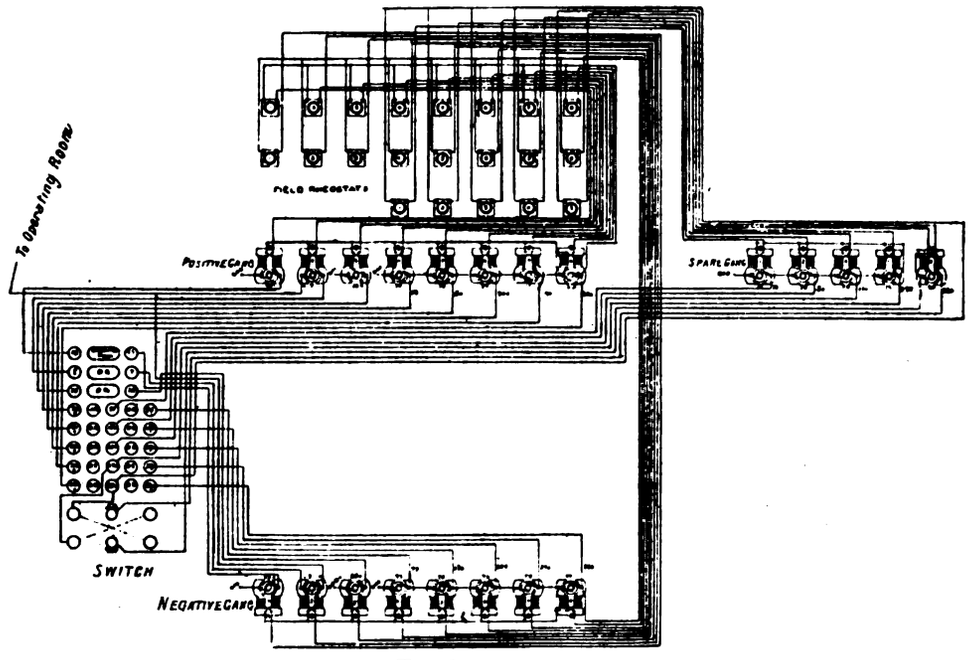

Fig. 1.

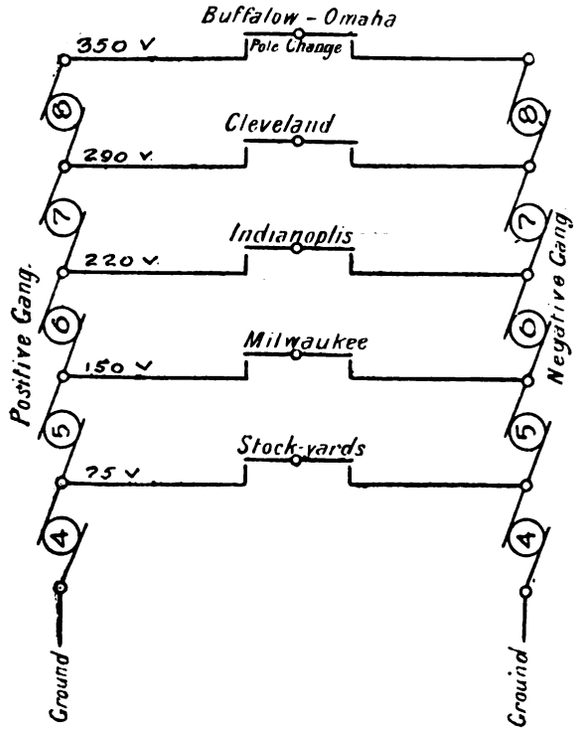

Fig. 2.

The supplementary battery of 25 small Crocker-Wheeler machines is in constant operation, any one of which may, from the switchboard in the office, be thrown into any circuit in lieu of an automatic repeater. For instance, Toledo might call up Milwaukee, and by the insertion of a plug in the switchboard one of these small generators is thrown into the circuit augmenting the voltage, doing away with the set of automatic repeaters, which otherwise would have to be used.

A peculiar feature of the entire plant is that only one generator (No. 8) in each gang is self-exciting, and part of its current excites the fields of all the other machines in the gang through suitable rheostats, and in this way the voltage of each machine is maintained at the figures as shown in Fig. 1, although all the machines are normally rated at 110 volts In addition to this, dynamo No. 4 of the positive gang then in operation energises the fields of the entire battery of 25 small Crocker-Wheeler generators, none of which are self-exciting.

The following table shows the normal load on the plant:

No. 1	45 volts	11 amperes		
,, 2	7 ,,	22 ,,		
,, 3	23 ,,	44 ,,		
,, 4	75 ,,	3 ,,	3 ,,	to line exciter.
,, 5	75 ,,	2·1 ,,		
,, 6	70 ,,	1·25 ,,		
,, 7	70 ,,	2·25 ,,		
,, 8	60 ,,	3 ,,	9 ,,	to line exciter.

The plan of doing away with self-exciting fields enables the operator to maintain the voltage within very narrow limits, and as the total load fluctuates very little a minimum of supervision is needed.

Lines from this office are worked as far east as Buffalo and Pittsburg, in the west to Sioux City, Omaha, and Kansas City, and in the south to Memphis, Tenn.—in other words, within a radius of about 500 miles. Beyond this radius automatic repeaters must be used for points outside.

This dynamo plant replaces a gravity battery equipment of about 60,000 cells, which number could scarcely be closely packed in twice the space occupied by the modern installation, to say nothing of the expense and labour involved in the maintenance of that vast number of primary batteries.

THE BRITISH ALUMINIUM WORKS AT FOYERS.

The British Aluminium Company was formed in December, 1894, with a capital of £300,000. It has a powerful board of directors under the chairmanship of Mr. R. W. Wallace, and includes Lord Kelvin amongst its scientific advisers. As will be remembered by our readers, a spirited correspondence in the public Press resulted from a letter written by the Duke of Westminster last July. We printed these letters in our issue for October 11 last. The statement of the Duke was to the effect that the aluminium works at Foyers would spoil the scenery of the district, and that poisonous fumes would be given off by

Digitized by Google

the process which would kill all the trees near the place. If this should have been so, it would be a matter of regret,

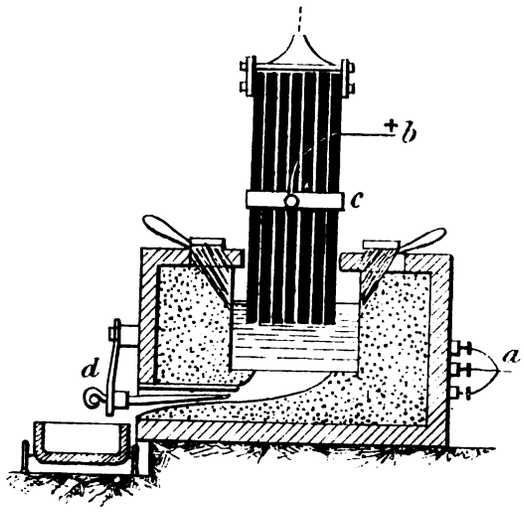

FIG. 1.—Section of the Aluminium Furnace.

although it is doubtful whether the gain in prosperity in the district would not more than compensate the inhabitants. Now the works are almost completed, one can judge as to whether the district will be permanently disfigured. From our illustrations, taken from the road crossing the pipe track, it will be seen that the shore of the loch is fringed by a belt of trees. These trees nearly hide the works from view when the observer is on a steamer on Loch Ness, so that all which can be seen at present is the pipe track. This track up the hillside had to be cleared in order that the pipes might be laid from the power-house to the penstock-chamber, but as soon as this work is completed the surface will be again covered by vegetation. The rest of the work consists of a tunnel to the river above the upper falls. The buildings can, of course, be seen when ascending the road leading to the falls, but as soon as the

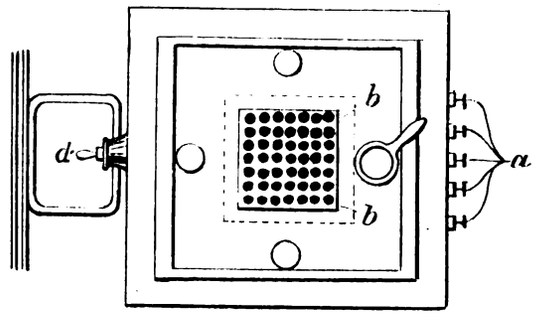

FIG. 2.—Plan of Furnace.

temporary work is replaced by stone buildings of the type shown in our illustration, there will be little in the architectural details that can be objected to by the extreme Ruskinite. As to the effect of the process on the vegetation, the surroundings of the works at Neuhausen, where a similar process has been working for some years, effectually disproves the statement that the trees will suffer.

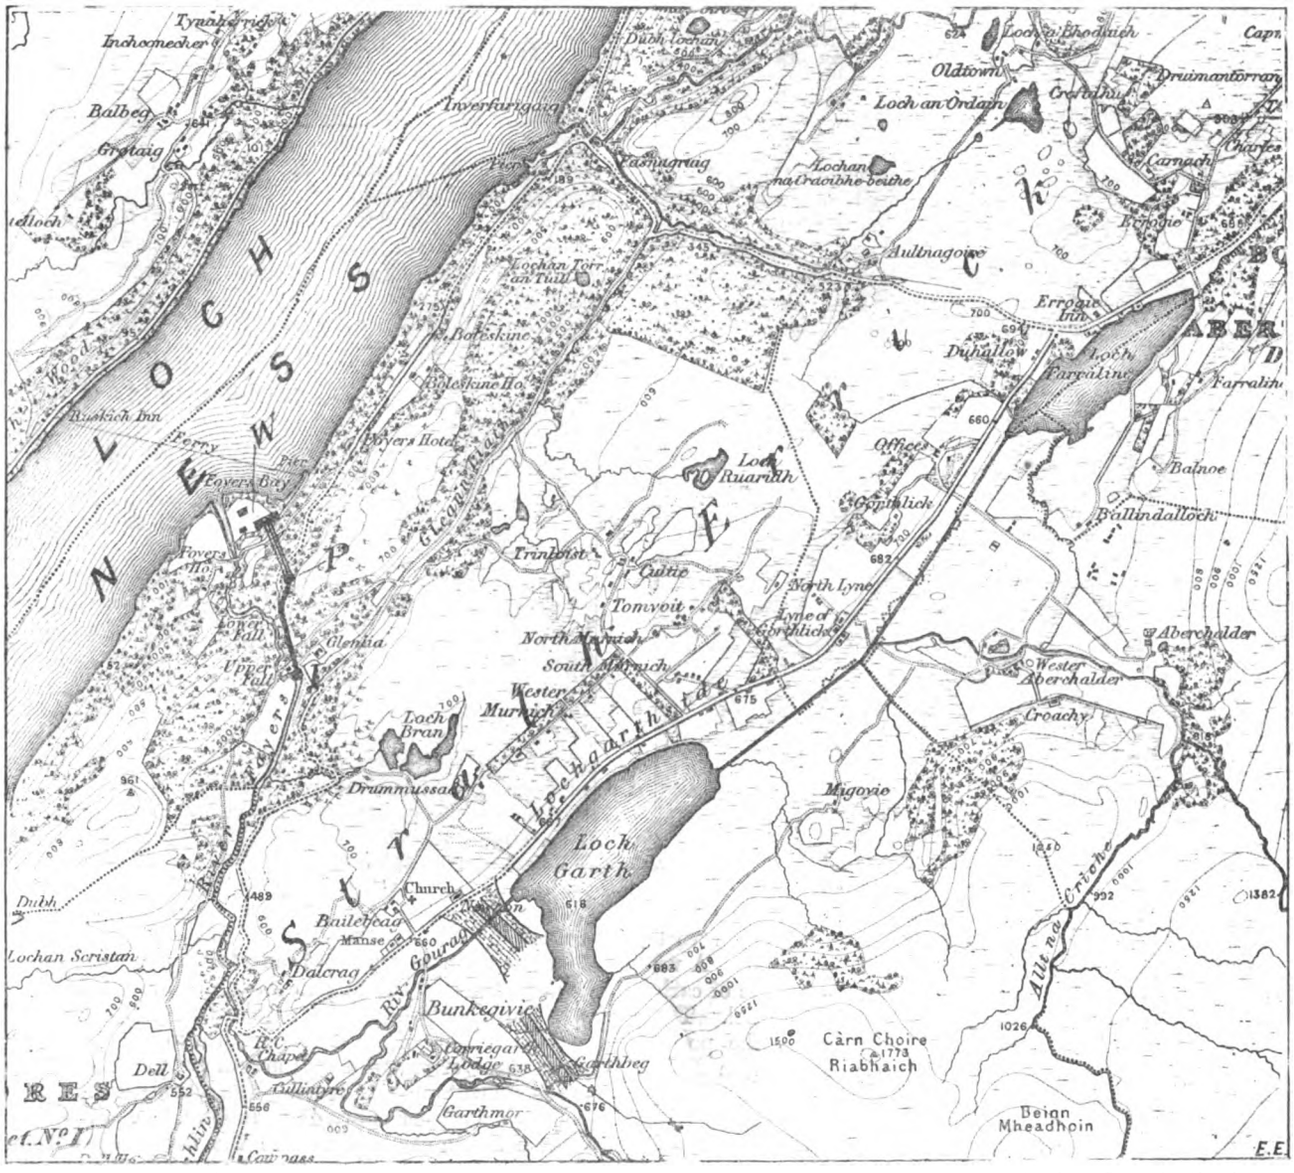

FIG. 3.—Map of the Country round the Falls of Foyers. W, British Aluminium Company's Works. P, Main Penstock Chamber. I, Intake Chamber. The Pipe Line. The Tunnel.

At Neuhausen the works are picturesquely situated amongst trees on the banks of the Rhine, and a recent photograph shows no signs of the alleged devastating fumes. The material used in the furnace is chemically treated at Larne, in Ireland, where the bauxite is found, so that only pure alumina is imported to Foyers. Hence no superfluous matter will have to be discarded at Foyers, and the heaps of *débris* expected by the enraged lovers of nature will not be formed.

The reduction of the aluminium will be effected by the Herault process, in which the purified alumina is melted and decomposed by the electric current. A carbon anode and a copper cathode are used if it is desired to produce aluminium bronze, but a copper cathode is not essential. With a carbon cathode pure aluminium can be produced. For this purpose the fusing and reduction take place in a rectangular iron vessel lined with carbon, which is connected to the negative terminal by copper leads, *a*, in Fig. 1. A wide aperture in the top of the vessel allows a bundle of carbon rods, *b* in the diagram, to descend into the vessel. These serve as the anode, and are connected to the positive terminal. The apparatus is shown in section in Fig. 1, and in plan in Fig. 2, from which the construction of the anode and its position in the cell is clearly shown. The bundle of rods forming the anode is hung from a balancing weight, so that its position can be easily adjusted. A copper frame, *c*, holds the carbons in their place, and at the same time forms the means of connecting-up with the cable conveying the current. At the commencement of the operation a very small quantity of copper is placed at the based of the carbon rods and melted by the arc. The alumina is then added, and electrolysis takes place under the influence of the current, the oxygen going to the carbon and forming carbonic oxide gas and the metal going to the bottom of the chamber. If pure aluminium is desired, as is the general rule, only alumina is added, and after the first lot is run off practically pure aluminium is obtained. The metal is run off into moulds from time to time, and fresh material supplied as is required. It is important that the alumina should be chemically pure. It is obtained from bauxite. The bauxite is heated with caustic soda, but not to a melting temperature, and the aluminate of sodium is extracted by water, the silicates, iron, etc., remaining behind. The alumina is precipitated by carbonic acid, washed, and dried.

The Works at Foyers.

The area from which the water is collected is a most extensive one, and a large part of this land has been acquired by the company. The water right also gained will allow them to construct the necessary works for storage of the water now running to waste in times of heavy rainfall. The question of the regularity of water coming to the falls is one of great importance to the company, and also to the tourists, who still may hope to enjoy a sight of the renowned Falls of Foyers. The scheme prepared by the company's engineer is briefly as follows. A fair proportion of the water in the river above the falls comes from the valley containing Loch Garth and Loch Farralin. As will be seen in the map, these lochs are some two miles apart, but there is little doubt but that originally they formed one large loch. The action of the stream has, however, scoured out a bed in the hard rock where it leaves Loch Garth, and so lowered the level of the water. The land now exposed between the two lochs consists mostly of a low-lying swamp, the difference in water-level

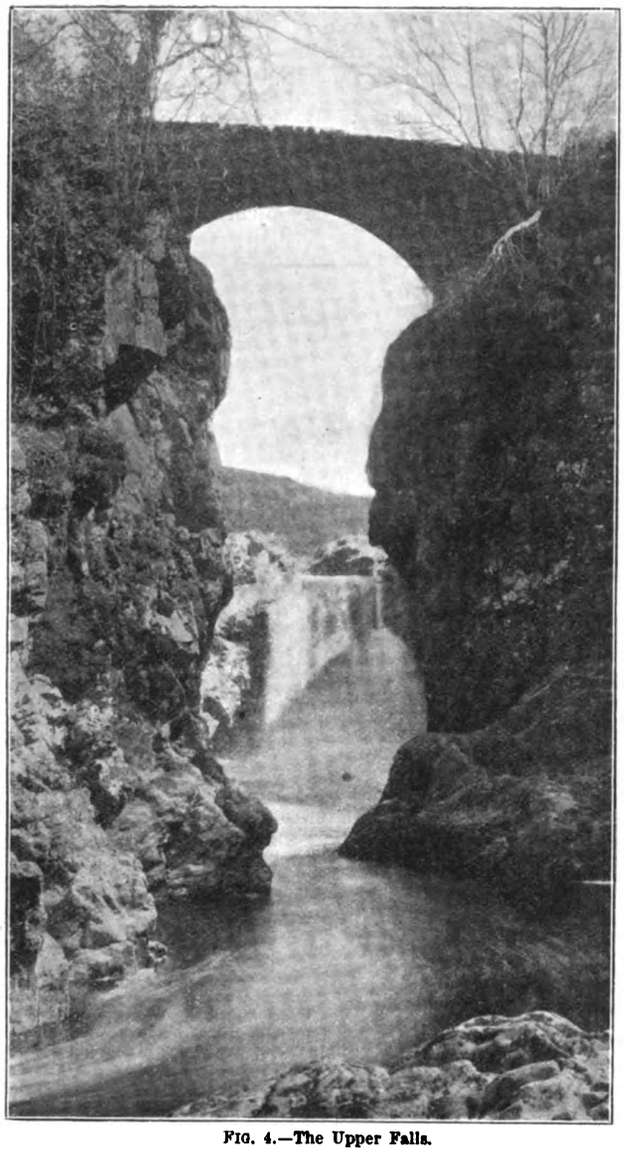

FIG. 4.—The Upper Falls.

FIG. 5.—The Lower Falls.

Digitized by Google

between the two being only about 10ft. The engineer proposes to build a weir and a dam at the lower end of Loch Garth, as indicated diagrammatically in the map (Fig. 3). The weir is placed across the small valley through which the River Gourag flows. The dam is required to fill in a slight depression in the formation in order that the new water-level may be attained. The land in the centre, between the weir and the dam, is sufficiently high to admit of the water-level rising some 20ft. This new level will submerge the whole of the land between the two lochs, and will form one large reservoir 4¾ miles long. The breadth will be also much increased, and the water-level where Loch Farralin now is will be raised by 10ft. In this large reservoir a vast quantity of water can be stored in the winter, and it will also collect the heavy spates in summer, which now swell the falls to an enormous extent for a short time. The heavy falls of rain cause the river at the point where the intake to the tunnel is placed to rise by an almost incredible amount, a rise of 7ft. in two hours being a not unfrequent occurrence. Such large volumes of water would be useless to the works, and it is expected that the reservoir will provide sufficient storage to supply both the works and the falls in times of drought. The area of the water basin draining into the falls is unfortunately outside the Scotch districts of exceptionally heavy rainfall, being situated rather too far eastward to catch the moisture brought inland from the Atlantic Ocean. The rainfall, however, averages about 40in. per annum, which is no inconsiderable amount. All the surveys have been completed for the weir and dam, but the construction of the masonry work has not yet been commenced. The normal flow of the river will suffice to work at least half the plant at present installed. The River Gourag takes the water from Loch Garth to the River Foyers, the length of this river being about two miles. The upper falls are about 1¾ miles below this junction. The intake to the tunnel is situated in a pool just above the falls. The penstock is of circular form, and is built of granite, of which there is an abundant supply on the estate. It has five gates, so that the water can be conveniently regulated. Connection will be made to this point by telephone, so that the man in charge can quickly shut off the water entering the tunnel in case of need. The tunnel between this point and the main penstock-chamber on the hillside above the power-house is about half a mile long. The tunnel is, roughly, parallel to the river gorge for the greater part of the distance, and a number of headings from the gorge are driving into the tunnel line. From these the spoil is discharged down the side of the gorge. The nature of the formation can be gathered from the views of the upper and lower falls (Figs. 4 and 5). The whole of the tunnelling had to be carried out through rock varying in nature from a mica schist to a hard limestone. The diameter of the tunnel is 8ft. throughout, and for the greater part of its length it is lined with concrete. The length next to the intake from the river is through such hard rock that no lining is deemed necessary. The majority of the headings are permanently closed, but in some cases a discharge pipe is inserted, by means of which the tunnel can be drained for inspection. The slope of the tunnel is very slight, as the section allowed is ample for the flow required, and consequently there is little loss of head between the intake and the main penstock-chamber. The construction of this tunnel has been carried out by Welsh miners working night and day since the autumn, and the hard nature of the formation has necessitated a liberal use of dynamite.

The main penstock-chamber is situated on the hillside, directly above the turbine-house, to which it is connected by a series of cast-iron pipes laid down the slope of the hill. The chamber is built on the rock, and is constructed of granite lined with concrete. It is rectangular in form, and of ample dimensions to form a settling-tank. The provision for excluding drift and rubbish at the intake is, however, likely to prevent much deposit being laid down.

FIG. 6.—View of the Works and Part of the Pipe Track at Foyers.

Provision is made in the wall facing Loch Ness for seven pipes of 30in. diameter and one smaller pipe. Two of these large pipes are now being laid, and two are completed ready for running. The diameter of the pipe is reduced by two steps to 20in. at the turbine. Sluice-valves are placed at the point at which the pipe leaves the penstock-chamber, and again at the turbine. At the upper end of the pipe line an inspection-chamber is provided in each pipe, which also gives air relief. The effective head obtained is over 350ft. A view of the pipe track showing the pipes in the trenches is given in Fig. 6, which also shows the main building, containing the generating plant and the aluminium furnaces. The land just beyond this building is flat, so that the trees on the shores of the lochs form a screen in front of the works. The photograph from which the illustration was made was taken from the public roadway.

The smaller pipe is to be used to supply two 50-h.p. turbines, which will be used for lighting and transmission of power purposes. It is proposed to light the hotel and the few other houses near, and perhaps eventually the model village to be erected for the employés will also be lighted electrically.

(To be continued.)

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

A PLEA FOR COMPOUND ARITHMETIC.

SIR,—As you have mentioned my writing, many years ago, against the French decimalism—which I still regard as barbarous and retrograde; but I have quite abandoned the system I then proposed to substitute—and my objections thereto apply equally to his duodecimals (or, indeed, rather more so), a few lines may suffice, I think, to explain the reason for compound arithmetic, which seems now quite misunderstood. Simple arithmetic consists in repeating a particular base upward and downward, and the most natural base is the number of our fingers. Hence have arisen the names hundred, thousand, myriad (now disused in English prose), million, billion, etc. The Hindoos have a far greater number of these. It is natural to extend any such system, and especially when some better base than 10 is taken. Twelve is a far better base, for the reasons Mr. Halliday explains. So is 8, which Charles XII. of Sweden wanted to introduce, but not so good as 12. But a far better than 12 is 60, which the ancient Babylonians really used, and which survives to our day in the divisions of hours of time, and of degrees of angle. This is what I ventured to revive (in the pamphlet he mentions) and to apply, as he would duodecimals, as a new simple arithmetic, to which all measures and weights would have to be adjusted. But I did not perceive, at that time, why simple arithmetic was justly modified into compound, and that compound arithmetic, except among savages, must prevail.

One line in Mr. Halliday's article (p. 430) gives the reason: "For the purposes of the engineer, it must be subdivided and multiplied by a number which admits of the highest form of sub-division." Exactly so, but powers of a number, of 10 or 12 or any other, will never admit "of the highest form of sub-division." This will be plain if we begin from 6, the lowest number that has two divisors (besides 1 and itself), and construct the series of what I would call *eumetric* numbers, each having more divisors than any number below itself.

6	has	2	divisors	1,260	has	34	divisors	55,440	has	118	divisors
12	,,	4	,,	1,680	,,	38	,,	83,160	,,	126	,,
24	,,	6	,,	2,520	,,	46	,,	110,880	,,	142	,,
36	,,	7	,,	5,040	,,	58	,,	166,320	,,	158	,,
48	,,	8	,,	7,560	,,	62	,,	221,760	,,	166	,,
60	,,	10	,,	10,080	,,	70	,,	277,200	,,	178	,,
120	,,	14	,,	15,120	,,	78	,,	332,640	,,	190	,,
180	,,	16	,,	20,160	,,	82	,,	498,960	,,	198	,,
240	,,	18	,,	25,200	,,	88	,,	554,400	,,	214	,,
360	,,	22	,,	27,720	,,	94	,,	665,280	,,	222	,,
720	,,	28	,,	45,360	,,	98	,,	720,720	,,	238	,,
840	,,	30	,,	50,400	,,	106	,,	1,081,080	,,	254	,,

The rule in school arithmetics called *Practice*, and the tables often added, called "practice tables," the "aliquot parts of a pound," or "of a ton," etc., show exactly the object for which the diverse weight-tables and measure-tables were devised. The blunder of their inventors was in making them *diverse* at all. Each trade got a fancy that certain habitual quantities, manloads or cartloads, were best for its own business, and each thus created its own table—"wool weight," "ale measure," and so on. But money being common and national, the coins were fixed nearly on the very best. The excellent "practice table" of a pound or £, arises from the number of pence in a £ being 240, one of the above eumetric figures. "Troy weight," being derived from the same Latin source as our money, has the same excellence in its numbers. But if we now turn to "avoirdupois" weight we find no 12, no 240, nor any of the figures in the above table. The 16oz. are not eumetric in themselves, though the ratio occurs between 1,260 and 20,160. Again, 2,240, the number of pounds in a ton, has but 26 divisors, or fewer than 720 has. Again, take our long measure: the mile is 380,160in., having but 142 divisors, the same as 110,880. So far are we from admitting "of the highest form of sub-division." On the other hand, in money, our largest coin (now out of use) was the five-guinea piece, of 2,520 halfpence, or 5,040 farthings, both numbers being in the eumetric table.

It may be observed there is one square eumetric, 36, and no other, and we can easily prove that no cube or higher power can ever enter the series. But I regard it as quite essential to a proper compound arithmetic, that the largest unit in each measure should be 720,720 times the smallest. Hence, it is not necessary for square or cubic measures to be numerically square or cube. The above number might result from a solid 88in. by 90 by 91; or it might, in land measure, be a surface, 840 × 858. Our present acre is not a square of any lineal measure. It is 22 yards by 220, or 44 by 110, or 55 by 88. The supreme number of every system being 720,720, this will be reached best by six steps of 7, 8, 9, 10, 11, 13. But it does not follow that they should be in this order, nor whether they should increase upward or downward. Above the largest, and under the smallest unit, we shall go decimally, and therefore it might be well to put the 10 at one end of the scale, making it, perhaps, 10, 9, 8, 7, 11, 13. But all these details I leave for discussion, the sole points now insisted on being the extent, and total figure 720,720.

In using the British foot, we must remember, it is also Russian and Swedish; and all the higher Russian units already multiply it by 7, as all the British do by 11. And it has two singular connections with 1,001, which Sir J. Herschel noted in his essay "On the Yard, etc." He had reasons for suggesting its increase by one-thousandth; but the same purposes would be served by merely multiplying by $7 \times 11 \times 13 = 1{,}001$. A remarkable natural fact, to be kept in view, is that the longest degree on earth exceeds the shortest as 100 to 99. Degrees and minutes are perhaps the very last kind of measure we may expect to change

To show that Halliday's duodecimals have no advantage, on page 432 he says, "The present second is one 86,400th part of a day, and the new second would be one 248,832nd." Well, 86,400 has 94 divisors and 248,832 has but 64. The latter has fewer than 10,080 has, the former has as many as 27,720 has. Such is the inferiority of *any* simple arithmetic to compound!—Yours, etc., E. L. GARBETT.

THE METRIC SYSTEM.

SIR,—Allow me to correct a statement made in your issue of to-day which may mislead your readers. At page 425, under the heading of "The Metric System," you say a metric ton weighs 2,204lb. approximately. This is only true when applied to distilled water at a standard temperature and pressure. The accepted weight of the cubic metre or ton for coal is 900 kilogrammes, or, say, 1,984lb., in France, and, if I remember right, 905 kilogrammes, or, say 2,000lb., in Spain. The great difficulty in correctly stating the weight in relation to bulk lies in the fact that coal of different classes runs in different sized pieces, and in other respects varies. Custom, therefore, has determined that the cubic metre or ton of coal in France should be taken as 900 kilogrammes.

The habit in French ports is to sell coal to English ships in tons of 40 cubic feet, and to French ships in 900-kilo lots of one metre cube. I can with safety venture the opinion that if the metric system were not maintained by law in France it would die a natural death.—Yours, etc.,

London, April 17, 1896. ROBERT KAYE GRAY.

THE INSTITUTION.

SIR,—Referring to the anonymous letter which we are astonished to see appearing in your issue of the 17th inst. on the above subject, we desire to state, in reference to the late presidential election, that the conclusions of your correspondent in regard to the Brush Company's officials are to our knowledge absolutely without foundation.—Yours, etc.,

R. S. ERSKINE.
ALFRED E. MAYOR.
April 20, 1896. A. A. C. SWINTON.

[We are glad to insert the above authoritative letter, but at the same time must point out that the views held by our correspondent are the views held extensively by many who have held aloof from or opposed the agitation connected with the Institution. Similar views were expressed to us before the election of president and council, and our correspondents (Messrs. Erskine, Mavor, and Swinton) ought not to be astonished at our giving effect to views so widely held. Surely it is but just that both sides should be heard.

Digitized by Google

As yet the opposition has had the talking and writing pretty much its own way, but from what we hear there is a limit to be made in what so many members have ventured to think approaches to personalities. The Institution is not a battle ground for splenetic exhibitions, nor should the lobby of the theatre be used as a canvassing ground by the friends of the agitators, as it undoubtedly has been. If Mr. Raworth was actuated solely in the interests of the Institution and had no mental reservation whatsoever in his criticisms of the balance-sheet, those criticisms could have been succinctly and clearly put in less than five minutes.—ED. *E. E.*]

SAFE v. DANGEROUS ELECTRIC LIGHT CURRENTS.

SIR,—As I have always from practical experience contended that electric light and power can be more efficiently and economically supplied to towns and urban districts within a radius of five or six miles by using continuous currents than high-pressure alternating currents, I was, to settle as far as possible the question of danger, impelled to write to the Board of Trade for information.

To my letter of enquiry they have courteously replied as follows: "In reply to your letter of the 9th inst. I am directed by the Board of Trade to state that they have been informed of nine cases of fatal accidents to employés at generating or transforming stations where high-pressure alternating currents are used, but that no instances have been reported in the case of low-pressure continuous currents."

As the information received is of great public interest I trust you will see the desirability of making this known to your numerous readers.—Yours, etc., A. L. FYFE.

[We would be glad if Mr. Fyfe will give us figures from his practical experience of supplying towns within a radius of five miles by low-pressure continuous-current plants, as we do not know where this has been done. We also point out that no deaths are reported to consumers on the high-tension systems, and that the nine deaths to employés would have been reduced more than 50 per cent. if the victims had obeyed their instructions and used the precautions provided. We might suggest to Mr. Fyfe that in his disinterested labours for the safety of the public he should take up a crusade against the use of water for drinking purposes, as owing to the number of deaths recorded from drowning, it must be a most deadly fluid.—ED. *E. E.*]

THE LOCOMOTIVE BILL.

SIR,—The Light Locomotive Bill which was recently introduced in the House of Lords is of such vital importance to the electrical industry that perhaps you will find space for the following.

Mr. Chaplin received the deputation headed by Sir David Salomons on February 12, after which I had an interview with him, and I wrote to him at length on the following day. I need not, however, trouble you with my letter of that date or Mr. Chaplin's courteous answer. When, however, on March 30 we were able to obtain a copy of the Bill I wrote to Mr. Chaplin a letter, copy of which I enclose, together with his reply. I am glad to be able to add that on Tuesday last Mr. Chaplin and Lord Harris did me the honour of receiving me at the Local Government Board. I found them most anxious to do all in their power to meet the reasonable requirements of all the industries interested in this particular Bill. They, however, are of opinion that it is essential some restriction should be placed on weight, as otherwise they fear that heavy traction engines will be run about the country and through our towns at a considerable speed. I am glad, however, to be able to add that though they were not able until after consulting with their technical advisers to determine the exact limit of weight that the Government may think necessary, yet I have no doubt when the Bill is read a second time in the House of Lords we shall find, instead of two tons, if not five, at any rate four tons will be substituted. Mr. Chaplin said that this is a matter of experiment, and that the Government, while most anxious to assist the industries connected therewith in every possible way, felt that until some experience was gained on the subject they must be very cautious. Electrical omnibus traffic can certainly be conducted with success with a weight of five tons, and I have very little doubt that even if we are restricted to four tons, we shall be able to do very well with this traffic in our London streets and in other towns.—Yours, etc., S. FLOOD PAGE.

[COPY.]

LOCOMOTIVES ON HIGHWAYS.

102, St. George's-square, S.W., April 1, 1896.

Sir,—I have the honour to remind you of the interview which you accorded me after you had received the deputation on the above subject, on February 12, together with my letter of February 13, and the answer of your secretary thereto. I am afraid that in the multitude of the business connected with your department you have overlooked your kind promise to bear in mind my representation as to the vital importance to the electrical industry of not limiting the weight of the omnibuses or carriages to be used in towns to two tons. I may state that this limit, which is unfortunately contained in the Bill, has created great consternation amongst those connected with the electrical industry. It was only the day before yesterday that we were able to obtain a copy of the Bill, and I have already received communications from several of the leading representatives of electrical work, suggesting my writing to the papers, holding meetings, etc. I have, however, such confidence in your promise as to feel assured that such public agitation will not be necessary. If this limit is maintained it will practically exclude the use of electricity for horseless omnibuses, though it is undoubtedly the safest, cleanest, and best for such carriages.

On Wednesday last I was speaking at the meeting of the Associated Chambers of Commerce as one of the council of the London Chamber, and, remembering your promise that you would bear in mind my representations on this subject, I stated that we might look forward to this Bill with complete confidence that there would be no restriction put on horseless omnibuses not found necessary with the existing omnibuses, and no unnecessary interference with the natural development of the electrical industry as applied to omnibuses, etc., in towns. Judging from the welcome this announcement received from the delegates of the Associated Chambers, I have no hesitation in saying that if it had entered into my mind that this prohibitory restriction of weight would have found place in the Bill, I should have been able to get a resolution passed unanimously asking you to withdraw your present limit, if, in fact, you thought it essential that there should be any limit whatever, or any restriction beyond that for street traffic in London at the present moment. You are aware that laden wagons of 16 tons are now legally permitted to traverse our streets, while the large three-horse omnibuses, weighing very many tons, are allowed the free use of the Paris streets.

This question is one of such absolutely vital importance to the electrical industry, which, as you are aware, has been most seriously hampered in this country by what is now recognised as erroneous legislation, that I do hope you will be able to remember your most kind promise to give effect to my representations, and that you will prevent the agitation which must immediately be excited if this most lamentable, unnecessary, and unjust restriction is maintained in the Bill.

Naturally, I will not ask you to see me with one or two other representatives of the industry during the short Easter holidays, but I shall be most glad if, before any public meeting is called, you would see me with one or two representatives of the electrical and carriage-building industries, so that if possible the necessity for this agitation may be done away with.—I have the honour to remain, Sir, your obedient servant,

(Signed) S. FLOOD PAGE.

To the Right Hon. H. Chaplin, M.P., etc.

[COPY.]

Local Government Board, Whitehall, S.W., April 2, 1896.

Dear Sir,—Mr. Chaplin desires me to reply to your letter on the subject of the Light Locomotives Bill.

The Bill has been introduced in the House of Lords in consequence of the pressure of other business in the House of Commons.

The question of the weight of the articles to which the Bill is to apply is a matter of detail, and Mr. Chaplin is perfectly ready to receive and consider suggestions on the subject, which is a new one to all concerned, and of which there has been so little practical experience.

He has forwarded your letter to Lord Harris, who has charge of the Bill in the House of Lords, and from whom your suggestions will, he is sure, receive every attention.

When the Easter holidays are over Mr. Chaplin will be very willing to see you, in company with Lord Harris, or to receive in writing any further statement on the subject which you may like to submit.—Yours faithfully,

(Signed) H. C. MUNRO.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

MUNICIPAL ELECTRICAL WORK.

It is with great pleasure that we reprint a paper and discussion from our contemporary the *Journal of Gas Lighting*. In the first place, we know that we have here in a condensed form the animus of the gas world against electrical progress. In the second place, we have concentrated into a small space all the facts, figures, and arguments which seem satisfactory and conclusive to the gas working world. We are glad to take up some of the points raised by this paper and discussion, though a detailed examination of the same would be impossible in the space at our command. The first point is rather of an abstract character, and may well lead to diversity of opinion. What class of work ought to be municipalised? We have long since come to the conclusion that in sanitary matters, in the provision of water and of light, among other things, the municipal authorities should reign supreme. The provision of light is for the common good, and, properly provided by the local authority, it can be provided initially and maintained more cheaply than by any other means. When carried out by other parties, the extra initial cost and the extra annual cost is a tax upon the community for the benefit of strangers, which the community ought not to bear. From these and other reasons we have always contended that there could be but one answer to the abstract question as to the proper authority under which to instal and distribute artificial light materials. In his paper Mr. Troughton deals with certain facts, and takes great credit to the gas company for things over which the gas company has no more control than has Paris of Troy renown. The increased demand upon a gas company is not due to the company's work, but is the result of the growth of surrounding population. When it is claimed as something good and beneficial that 10, 11, 12, and 12½ per cent. dividend is paid in respect of a gasworks, we contend it means that the gas company reaps what it has not sown, and mulcts the commonalty of that money which it has neither worked for nor deserved. If the expansion of trade depended upon the merit or the work of the company, it would be another matter. It does not. The building of houses has nothing to do with the company, nor has the agglomeration of population. In our opinion, the declaration of huge dividends and the appreciation of value of shares in this class of concern is a discredit rather than a credit, and points to the absolute necessity of getting rid of obnoxious monopolies. What crass stupidity must exist if anyone imagines the giving of money to a town in such a case is unaccompanied by a more than corresponding giving to the company. Neither small nor large towns are being rushed into electric lighting schemes. They have been quiescent too long, and are beginning to see that the incidence of rating and paying of other folk's dividends may be ameliorated by taking this work into their own hands. The discussion brings out other amusing points, not the least suggestive of which is the careful suppression of facts and the gleeful production of exceptions. The introduction of any big industrial revolution cannot be accomplished without failures. Such failures can always

Digitized by Google

easily be accounted for, and it does not redound to the credit of opponents to try to make it appear as if the failures were the rule and successes the exception. Mr. Dixon probably thought he scored a point by referring to Cowpen and its failure, but how far his conclusions are discounted by the phrase "to lay down a proper installation," he forgets to say. A boy with a bent pin does not expect to catch salmon like a well-equipped angler, nor do you expect to succeed with an "improper" as with a "proper installation." Further, does it not go without saying that people must not overlook the fact that with increased consumption electrical energy can, as well as gas, be supplied at a cheaper rate? A point raised by Mr. Barton is just as misleading when he compares the candle-power cost of a big gas lamp with the candle-power cost of a little incandescent lamp; why did he not compare his gas candle-power cost with that of an arc lamp? Electrical engineers are tarred with the same brush, and too often make misleading statements by comparing things that ought not to be compared. The last point to which we will call attention is another relating to comparisons—the comparison of cost and returns from a small electrical installation in its early days with the cost and returns of matured gasworks. These figures, to be just, should relate to works comparable in size and being in full working order. However, we should have little to fear from an unbiassed examination into the results of central-station working; but our remarks on this point must be deferred. It may be well to mention that, so far as Newmarket specially is concerned, the electrical question did not arise as between the local authority and the gas company, but a private company, strongly supported, wished to instal electricity at Newmarket, and the authority was called upon to come to a decision whether it was advisable to allow this private company to enter upon the work or to undertake it themselves. We think the decision to undertake it themselves was the best possible.

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

BY DR. ARMSTRONG, F.R.S.

(Continued from page 440.)

Probably no discovery could be made which would be of greater technical importance than the discovery of a method of burning fuel electrically—*i.e.*, so as to produce electricity instead of heat. Hydrogen may be burnt electrically in the manner discovered by Grove, apparently because it is possible by means of platinum to connect both hydrogen and oxygen in circuit with an electrolyte such as diluted sulphuric acid; but we have not yet succeeded in discovering a method of "plating" a conductor with carbonic oxide which would enable us to arrange it in a circuit with oxygen. If this could be done, probably the problem would be soon solved. In the case of solid fuel the problem presents other difficulties, especially that arising from the want of suitable electrolytes: thus, although heated lead oxide is readily reduced by carbon, it does not behave as an electrolyte when the attempt is made to burn carbon electrically by means of it, the action being purely local. In like manner we have to discover a means of converting nitrogen into either ammonia or a nitrate comparable with that which apparently enables the papilionaceous plant or associated bacteroid to assimilate nitrogen from the atmosphere.

Having broadly laid down the principle that chemical changes consist in the exchange of ions, and therefore take place exclusively between ions, the "ionists" may be presumed to accept the view that chemical and electrolytic changes generally are synonymous operations. This being the case, it is remarkable how little has been done by way of applying the hypothesis except as a means of correcting values obtained in working with solutions which behave as electrolytes. The expansion and application of Faraday's conceptions to the explanation of chemical change generally appears indeed to have been retarded rather than advanced by the assertions formulated by the advocates of ionisation as a precedent cause of chemical change; indeed, Faraday's writings appear to have received no notice from the school. No attempt has been made to differentiate electrolytes from dielectrics by explaining either the essential peculiarities of either class or the co-ordination of composition—*i.e.*, structure and function—or to explain the extreme readiness with which dielectrics are in many cases acted on, or to define the conditions under which chemical change will occur; or to explain the readiness with which a minute amount of "impurity" will often condition change.

Whatever hypothesis be adopted, the determination of the essential qualities of an electrolye—a correct answer to the question, What is an electrolyte?—is of fundamental importance. The electricians would say it is a substance which, whilst conducting, undergoes decomposition, which is a purely practical definition. The "ionists" say that it is a substance in a state of ionic dissociation; but theirs is a dissociation of a most mysterious kind—confined to a very limited number of substances—affecting members of the same group in a most arbitrary manner, as whilst some respond others do not to the call to ionise on entering into solution—in no way to be co-ordinated with their relative stability as determined by any ordinary chemical method—and conditioned by the agency of a solvent which, though by hypothesis a mere screen, yet exercises a most potent influence, at solvents generally besides this one have little if any action. I discussed the question tentatively at Aberdeen, but did not arrive at any satisfactory conclusion as regards compounds which, *per se*, act as electrolytes. Facts have since come to light which make me more hopeful. In the case of the metallic protochlorides, so many of which are electrolytes, whilst the corresponding perchlorides are not, electrolysis involves the chloride acting both as electrolyte and "chlorine depolariser," and it is conceivable that the occurrence of decomposition is dependent on and in a measure conditioned by the depolarisation—in other words, that separate molecules are conjointly influenced by the E.M.F., and that while under it the one molecule promotes the decomposition of the other. The readiness with which the silver and lead haloïds undergo electrolysis may be explained in a similar manner, if it be assumed that they are capable of exercising at least a temporary affinity for halogens. It is remarkable that the elements from which electrolysable haloïds are derived occur closely together in the periodic system, and it may be said within the section of the alkali metals. As the alkali metals form tri-iodides, and similar compounds have been obtained from silver haloïds, as well as tetra-haloïd compounds of lead, there is reason to believe that the power of attracting halogens here postulated is actually existent, especially at high temperatures, when the fundamental molecules may be supposed to be more or less free from mutual control, and more likely, therefore, to form compounds with other elements.

From this point of view the behaviour of silver haloïds and of other substances which act as simple electrolytes is strictly comparable with that of composite electrolytes, as I have termed conducting mixtures of dielectrics; and if such a view could be accepted the phenomenon of electrolysis would appear to be strictly comparable with those of chemical change; both would occur within complex molecular systems. The behaviour of aqueous solutions on electrolysis may conceivably be more analogous to that of haloïds than is commonly supposed if it should turn out, for example, that in the case of solutions of sulphuric acid in water the first products of electrolysis are, as I have tentatively argued (compare *Proceedings*, 1893, 190), hydrogen and *persulphuric acid*. As I will show later on, it would not be difficult to apply a similar hypothesis to other acids and generally to aqueous solutions, especially if water be the *significant* substance in all these changes.

In discussing this, it is necessary to consider the acids themselves, as the suggestion here made in a measure involves the conception that acids such as sulphuric acids are hydrates, not hydroxides. Without attempting to discuss this matter in detail, I may say that, in my opinion, there is no evidence which in any way obliges us to regard sulphuric acid as $SO_2(OH)_2$; on the contrary, all the arguments are equally compatible with the assumption that it is a compound such as may be represented by the formula $SO_3 \cdot OH_2$, in which the radicles SO_3 and OH_2 are still preserved. There is no reason why such a view should not be extended to all "inorganic" acids, and if it be assumed that solutions of the halhydrides contain hydrates, the behaviour of such solutions as acids is strictly comparable with that of acids generally. Organic acids are peculiar in so many ways that they may well also be peculiar in their constitution, and different from those derived from elementary oxides.

* Presidential address delivered before the Chemical Society.

If sulphuric acid be a hydrate—viz., $SO_3 \cdot OH_2$—persulphuric acid is probably $SO_3 \cdot O_2H_2$,* and the formation of the latter during electrolysis as the primary product would, in a sense, involve the oxidation of water, so that the change would be similar in form to that which I have supposed to occur when a silver haloïd is electrolysed. By thus extending the view that electrolysis is the outcome of the combined action of the E.M.F. and of some effect which the one set of molecules exerts upon the other set while both are under the influence of the E.M.F., a clearer conception is gained of the possible nature of the effect which the one set of molecules exercises on the other set. The peculiar value of water as a solvent is also in a measure explained.

As regards the differences observed between acids, I have elsewhere pointed out in a note on the formation of salts (Chem. Soc. *Proc.*, 1891, p. 118), that "it may be supposed that in all cases the acid and the base in the first instance combine, and that the salt is formed by subsequent interactions within the molecule. In like manner, acids form dissociable compounds with water, and it is by the occurrence of change within such systems under the influence of an E.M.F. that electrolysis is effected. In those cases in which the compound is highly unstable and prone to dissociate, the opportunity for change to take place within the system is but slight, and consequently the acid is a weak one, and its solution of relatively low conducting power."

The argument here used would apply equally to alkalies and salts, although it may be doubted whether dissolved salts as such promote electrolysis; it is not improbable that they are more or less hydrolysed, and that the products condition electrolysis. On this assumption the conductivities of salt solutions afford a measure of the extent to which hydrolysis has taken place in them.

Experience shows that action at once necessarily takes place so soon as a conducting circuit is established, provided that the sum of the changes be exothermic—thus, copper readily dissolves in cold dilute sulphuric acid if coupled with platinum in nitric acid, or in presence of oxygen, although the heat of dissolution of copper in sulphuric acid is negative. This principle is one of extraordinary importance, and I desire to draw attention to one illustration of its application which I believe to be of consequence. It is well known that Baeyer in 1870 pointed out that the resolution of glucose during fermentation into alcohol and carbon dioxide, and, indeed, the phenomena of fermentation generally, may be accounted for by the assumption that translocation of hydrogen and oxygen atoms is induced through the alternate separation of the elements of water and their addition in different order, changes which would involve the accumulation of oxygen atoms at certain parts of the molecule, thus constituting points of weakness where disruption of the molecule would inevitably occur. This is shown in the following formulæ, in the second of which the separating elements are indicated by dots:

I.		II.		III.
$CH_2 \cdot OH$		$CH_2 \ldots OH$		CH_2
$CH \cdot OH$		$C \cdot OH \ldots H$		$CH \cdot OH$
$CH \cdot OH$		$C \ldots OH \ldots H$		$C(OH)_2$
$CH \cdot OH$	→	$C \cdot OH \ldots H$	→	$C(OH)_2$
$CH \cdot OH$		$C \cdot OH \ldots H$		$C(OH)_2$
$CH(OH)_2$		$CH \ldots (OH)_2$		CH_2

It will be seen that in the product of rehydration (III.) the terminal groups are fully reduced, whilst there has been an accumulation of OH groups in other parts of the system. In a molecule so constituted, changes might then set in similar to those involved in the resolution of oxalic acid into carbon dioxide and formic acid.

The conception is one of remarkable beauty, and undoubtedly a sufficient explanation, as changes precisely similar to those attending fermentation may be effected by simple hydrolysis: thus glucose may be converted into lactic acid by heating it with alkali; and on boiling fructose with muriatic acid an acid is formed—*i.e.*, lævulinic acid—$CH_3 \cdot CO \cdot CH_2 \cdot CH_2 \cdot CO_2H$, the production of which clearly involve a reduction of some of the $CH_2 \cdot OH$ and $CH \cdot OH$ groups, and oxidation of others, in the manner pictured by Baeyer. The only difficulty is to account for the occurrence of such changes under the conditions prevailing during fermentation, and here Baeyer has left the problem unsolved.

I have already drawn attention to the manner in which, perhaps, enzymes promote the hydrolysis of glucosidic compounds. A slight extension of the hypothesis appears to be all that is required to afford an explanation of the changes attending fermentation. Such changes are known to occur entirely within the cell, and are, presumably, functions of the protoplasm—in other words, they probably occur within very complex molecular systems of extreme instability; perhaps under the influence of, in contact with, the very same hydrolyst (enzyme) which, when separated from the cell, is so active in promoting the hydrolysis of cane sugar; or, if not, of substances of a similar nature. On inspecting Baeyer's formulæ it will be noticed that during rehydration the elements of the water molecule become added on to non-contiguous carbon atoms, and this is not improbably frequently a special feature of such changes. Supposing that the protoplasmic hydrolyst were to condition the formation of a conducting circuit in which any two of the carbon systems ($CH_2 \cdot OH$, $CH \cdot OH$, or COH) of the glucose molecule and water molecules were included, if the total hydrolytic change which could take place in such a circuit were exothermic, even if the change affecting the one group involved an expenditure of energy, water would be electrolysed, and its hydrogen would effect the withdrawal of OH from the one group and its displacement by hydrogen, while oxygen would be added to the other group, it may be directly, or in consequence of the displacement of H by OH. The different effects produced by different organisms, on this hypothesis, would be the consequence of the hydrolysis affecting different systems. As most, if not all, fermentable compounds are asymmetric, and the enzymes are undoubtedly also asymmetric bodies, the direction of attack would depend on the character of the asymmetry of both hydrolyte and hydrolyst (for nomenclature see *Trans.*, 1890, 528), and only compatible hydrolysts—*i.e.*, those compatible with the hydrolyte—would condition hydrolysis and fermentation. I venture to think that the hypothesis here put forward not only affords a sufficient explanation of the occurrence of change in the manner suggested by Baeyer, but is also of value as indicating a process by which the "energy" which is in defect in one part of a complex molecule may be supplied from another part, a point of some importance, as E. Fischer's marvellous researches on the carbohydrates and similar compounds clearly prove that the several groups of which the carbon atoms are centres in such molecules are practically independent systems which require to be individually influenced.

Considerations such as these may obviously be applied to all cases of chemical change in which complex asymmetric compounds are concerned, and are possibly of wide application in explanation of the chemistry of vital processes, including those of disease and death.

The introduction of new elements into the circuits within which normal changes occur, even if these were to remain conducting, would necessarily condition some variation in the rate, if not in the character, of the change, and even neutral substances would interfere and affect the rate of dissociation (hydration), for it is probable that the systems under consideration are eminently unstable. The interposition of non-conductors would cause "death" within the circuit affected, and hence indirectly in others. The effects produced by alcohol are, perhaps, explicable from this point of view.

In the case of vital processes, it may be pointed out that one great distinction which apparently may be drawn between actions taking place under "vital" conditions and those effected in the laboratory arises from the circumstance that in the former case a number of changes of distinct types may more often take place, if not simultaneously, at least in rapid succession, affecting different and, it may be, distant parts of a molecule. It would seem that while included within the protoplasmic molecule, in some cases also protection is afforded to that part of the molecule which if free would be the first to suffer, as in the case of the oxidation of glucose to glucuronic acid, for example, the attack being consequently directed into unusual channels, and that in others molecules are brought into association and caused to interact, which under ordinary conditions would fail to affect each other.

Whatever the nature of "protoplasmic" molecules, they must be of extreme complexity, and, consequently, they must present very many active regions to which other groups may become attached and within which therefore circuits can be established; hence the marvellous power of protoplasm of conditioning a great variety of changes; and it is doubtless the marvellous complexity of the albuminoids which renders such diversity of type possible in both the animal and vegetable kingdoms. Protoplasmic molecules may indeed be likened to a huge modern manufactory within which a great variety of operations are being carried on—almost all, in fact, that are necessary for the production in its finished state from raw materials of the particular article manufactured; many of the operations go on independently, others consecutively and dependently; yet all are carried out under one guiding impulse, within one sphere of action.

It can scarcely be doubted that the truth of Faraday's doctrine of the unity of chemical and electrolytic change will ere long be generally recognised now that it has been shown in so many cases that interaction does not occur between *two* (pure) substances.

* Berthelot has actually obtained a persulphate from sulphuric anhydride and a peroxide.

The essential moment conditioning the occurrence of chemical change, according to the view of which I am an advocate, is the formation of a conducting system in which electrolysis can occur, and within which, as already said, change will necessarily take place so soon as the system is established, if exothermic change be possible under the conditions—as in the case of any voltaic cell. Substitutions on this hypothesis are but secondary results consequent on additions.

Much has been done of late to discover that water plays an all-important part in determining many chemical changes, but the nature of the influence which it exerts has been little considered, and I am alone, I believe, in pointing out that mere moisture should be insufficient to condition change in many cases—in the formation of water, for example, from hydrogen and oxygen, the interaction of nitric oxide and oxygen, or the action of chlorine on metals, etc., as in such cases there would not be an electrolyte present. On the other hand, it would presumably suffice to determine the interaction of ammonia and hydrogen chloride, for example, as the latter and water together form an electrolyte. I believe this to be the criterion by which the efficiency of water *per se* may be judged of: in other words, that it will *per se* condition the occurrence of an interaction between two substances only if it be capable of forming a composite electrolyte with at least one of them; in all other cases something besides water must be present which will render the water conducting by forming with it a composite electrolyte. The number of such substances is, as already pointed out, comparatively limited.

In further illustration of this argument, the rusting of iron may be referred to, notwithstanding its importance and the amount of discussion it has given rise to, the exact nature of the change is by no means determined. According to Crum Brown (*Journal*, Iron and Steel Institute, 1888, 2, 129), liquid water, oxygen, and carbon dioxide are the essential elements concerned in the formation of rust. But it may well be doubted if a solution of carbon dioxide in pure water be an electrolyte, in which case perhaps the carbon dioxide initially but serves to promote the formation of acid from a trace of some salt which happens to be present, and the primary product derived from the iron is the corresponding iron salt; this last, however, being even more amenable to attack by carbon dioxide than the salt originally present, the acid is continually regenerated. On this view it is easy to understand the protection afforded by an alkali. I have on more than one occasion urged that probably it is always necessary that liquid water systems should be formed if change is to occur, at least in the case of changes taking place under ordinary conditions—*i.e.*, at ordinary temperatures. Apparently it is only at high temperatures or under the influence of an electric discharge that this condition need not be secured, and in such cases it may be supposed that the conditions are such as to favour the momentary formation of what are practically liquid systems in the atmosphere within which the change occurs. It is not improbable that the influence which surfaces often exercise in promoting gaseous changes may at least in some part be due to the increased opportunity they afford for the formation of liquid systems to take place.

The absolute function which the (composite) electrolyte fulfils in such systems is obscure at present, as it is but stating a fact to say that the presence of a conductor is essential in order that a current may flow; it would seem not improbable that it in some way constitutes a mechanism whereby the discharge or degradation of the energy expended in the change is effected. The question is one of great interest and importance, especially when viewed in connection with the enquiry into the nature of valency and with the fact that an action impossible within an endothermic system at once takes place when an element (a depolariser) is introduced which constitutes the system one within which as a whole endothermic change can occur.

H. B. Dixon's observations on the combustion of carbonic oxide, as well as those of Victor Meyer and his co-workers on the formation of water, and also those of Pringsheim, followed by those of Victor Meyer and Bodenstein, on the formation of hydrogen chloride, all bring into prominence the fact that the occurrence of change in gases is dependent on conditions which are essentially of the same order as those obtaining in the case of liquids. Prof. J. J. Thomson's observations on the discharge of electricity through gases (*Phil. Mag.*, 1893, 36, 313) apparently prove that what is true of chemical change is equally true of the electrical discharges which can be produced in rarefied gases—that the phenomena in both cases, in fact, are electrolytic manifestations, and that discharge could not take place in a pure gas. It appears to me unnecessary to assume that such changes are dependent on the occurrence of atomic dissociation of the molecules of the interacting substances prior to the formation of the molecules of the substances which are the ultimate products; indeed, the observations referred to may almost be regarded as proof that such is not the case. No more striking evidence that the occurrence of a discharge in a gas is dependent on the presence of a something besides the gas—on the formation of a complex conducting system—could be given than is afforded by the beautiful experiment exhibited by Dewar at the Royal Institution, showing that the discharge at once ceases in one of Crookes's phosphorescent tubes on cooling with liquid oxygen. Such treatment cannot be supposed to cause the condensation of the residual air, but may well condition the deposition of the traces of vapour (? of conducting water) present in the gas, thereby destroying the systems within which conduction can alone occur.

It may be here pointed out that this argument is perhaps also at least partially applicable in explanation of the erratic behaviour of the discharge in vacuum tubes. If the discharge occur within a complex system, it may well be that certain conditions will favour the formation of a conducting system including one, and others of a system including another, of several substances present in a tube—such an explanation, for example, would account for the fact that the mercury spectrum is only sometimes seen in tubes connected with a mercury-pump. And having regard to the fact that a gas may exhibit several spectra, it may be that the spectrum of a given substance varies more or less according as it is included in one or other of several conducting systems.

If the occurrence of chemical change be dependent on the formation of liquid or quasi-liquid systems, the reduction of temperature sufficiently to produce solidification should prevent change. This is probably the explanation of observations such as have been made by Dewar and Pictet. There is probably no more effective method of drying, if drying be defined as the removal of liquid water, than that afforded by cooling to the very low temperatures obtained with the aid of liquid oxygen. In like manner, I am inclined to doubt whether any photographic action be possible at very low temperatures and would attribute the slight effect observed by Dewar to the action of the phosphorescent light emitted by the plate itself on the sensitive film after the temperature has risen sufficiently for the water within the film again to become liquid. I have long been convinced that photographic phenomena and procedure can and should be treated from the electrolytic point of view (*Camera Club Journal*, 1892, 61, 124; 1893, 48, 71).

We are but beginning to recognise that what is true of ordinary interchanges—*i.e.*, that the change takes place within a complex conducting system—must be equally true of changes of the converse order, so-called decompositions, including dissociation phenomena generally. Among the chief experimental contributions to our knowledge of this subject, we may reckon first and foremost the classical work of Grove on the decomposition of water at high temperatures, and the observations of Deville, as well as those of Victor Meyer and Langer, showing that the decomposition of carbon dioxide takes place in porcelain at a temperature several hundred degrees below that at which it occurs in platinum vessels. Perhaps Frederick Siemens, more than anyone, has dwelt on the influence of conditions other than those of mere temperature on the stability of substances at high temperatures.

It must always appear paradoxical that water should undergo decomposition at a temperature which necessarily must be below that which can be developed in its formation by combustion from hydrogen and oxygen; or, assuming that the effect is primarily of an electrical character, that it should be decomposed by an E.M.F. lower than that which can be developed by the interaction of the elements into which it is resolved.

The problem is akin to that involved in the electrolysis of water, which can be effected by E.M.F.'s much smaller than about 1·4 volts, the value calculated from the known heat of formation of water.

Two explanations are possible—one involving the assumption of dissociation, the other of an available external source of energy; it is needless to say that the former has long been the popular view. Reference has already been made to current views on the dissociation of water, and the question raised whether we are justified in concluding that water under ordinary conditions is dissociated, even to a very slight extent. But, whatever the ultimate conclusion, even if pure water be undissociated and an absolute dielectric, it may well be that in the case of a conducting mixture we are dealing with systems which, although free from any elements of dissociation, may yet be prone to undergo internal changes much after the manner of those pictured by Williamson in his celebrated essay on etherification (*J. Chem. Soc.*, 1851, 4, 110), changes which, as Fitzgerald has pointed out, would in effect be of the same order as those postulated by the modern school of dissociationists. On the other hand, it is not impossible that our conclusions are all based on observations made either with polarised electrodes or with media which have been to some extent impure.

In the experiment devised by Helmholtz and described in his Faraday lecture, the attempt was made, by means of an additional electrode of palladium which could be charged with hydrogen, to remove all traces of dissolved oxygen, and this object is supposed to have been effected; but I venture to doubt the possibility of securing complete depolarisation in such a manner.

With regard to its behaviour at high temperatures, if pure water be to some slight extent dissociated, even under ordinary

Digitized by Google

conditions, as is suggested, it may fairly be expected that it would undergo further dissociation, to a greater extent and more readily than appears to be the case, as the temperature is raised; the important experiments made by V. Meyer and Langer on the behaviour of various gases at very high temperatures apparently also lend no support to this view.

GAS v. ELECTRICITY AS AN INVESTMENT FOR TOWNS.*

The fifteenth general meeting of the Eastern Counties Gas Managers' Association was held on the 15th inst. at East Dereham, when Mr. Troughton read the following paper:

It recently occurred to me, after I had received several disappointing letters from our members declining to read a paper or get up a discussion, that I might give you a few figures relating to the growth of the Newmarket Gas Company, and its relation to the town as an investment, with the view of raising a discussion. Briefly, I may say that we are threatened with the electric light—first, by a private company who gave notice to the Board of Trade last October of their intention to apply for a provisional order; and, secondly, by the local authority, who have decided to oppose the company, because in years gone by the authority missed acquiring the gasworks and waterworks, which have turned out such good investments. Consequently, they made up their minds to apply for a provisional order, so as not to miss any more good things; and they will do so, I presume, next autumn. This opposition has, of course, stopped the company.

In passing, I may say that our town surveyor estimates that an electric installation costing £10,000 can be put down in Newmarket and worked at a profit of £600 a year. That 6 per cent. will be very nice when they have made it; but we hear of so many electric concerns that earn nothing at all, and so few that earn 6 per cent., that we may be excused for being somewhat dubious. I know several large towns which are supplying electricity at a loss.

The point I want to bring before you is that a gas company in a small or medium-sized town, with a growing business, is a better investment to the consumers of gas, who are the ratepayers, than is an installation of electric light, whether it be supplied by a company or by the local authority. We make and sell four times the quantity of gas that we did 20 years ago; and we are selling it at 2s. per 1,000 cubic feet less than we were then. I will give you a short statement of the growth: In 1875-6 we made 11½ millions, and sold it at 5s. 10d. per 1,000ft.; in 1879-80 we made 17¾ millions, and sold it at 5s. per 1,000ft.; in 1883-4 we made 22¾ millions, and sold it at 4s. 6d. per 1,000ft.; in 1889-90 we made 36½ millions, and sold it at 4s. 2d. per 1,000ft.; in 1894-5 we made 46½ millions, and sold it at 3s. 10d. per 1,000ft. This reduction in price is entirely due to the expansion of the company's business. The difference between 5s. 10d. and 3s. 10d. means that on our last year's sale of gas over £4,200 per annum was given back to the consumer by way of a reduced gas bill, and this sum will go on increasing with the company's business. Besides this, we have paid dividends for several years of 10, 11, and 12 per cent., and the last dividend was at the rate of 12½ per cent. upon all our capital.

Last year we obtained a special Act of Parliament, with the sliding scale and auction clauses inserted, which provides that all new capital shall be sold by auction or tender, and we expect to raise the £15,000 of new capital authorised at about 4 per cent., and the £15,000 of loan capital authorised at 3¼ per cent. We are at present offering £5,000 of debenture stock at 3¼ per cent., and this money will be expended on extensions as the demand arises. You will thus notice that we have power to raise £30,000, which we expect to get at from 3½ to 3¾ per cent., instead of alloting it among existing shareholders at par as formerly, and paying the usual 10 or 11 per cent. dividend upon it. There is a great saving here, and it affects the consumers of gas very considerably. If this capital is properly laid out on extensions, it should (and I think it will) earn 12 or 13 per cent. After paying the interest on it 9 per cent. will remain, which on the whole of the new capital will amount to £2,700. That will be apportioned under the sliding scale as follows: 73 per cent., or £1,964, of this sum will go annually into the gas consumers' pockets instead of into those of the shareholders as formerly, and only the remaining 27 per cent., or £736, will go to the original proprietors. I think this gives the consumers of gas a large interest in future extensions and developments of the gas company, which to a very great extent is carried on for their benefit, so far as future business is concerned; and the consumers are the general public, for, with the aid of the slot meter, we shall soon have everyone using gas.

I think a town that had quadrupled its make of gas in 20 years, and reduced the price 2s., may reasonably be expected to double again in 15 years, and at our present rate of growth we estimate that we shall do so. Assuming that we do, and are selling in round numbers 100 million cubic feet (which I do not think is an extravagant estimate), we ought, owing to the growth of the business, the benefit we shall have from cheaper capital, and the economies in production that follow growth, to be selling gas at 2s. 6d. per 1,000 cubic feet. This on a sale of 100 million cubic feet would mean the enormous sum of £6,666 being returned annually to the consumers of gas in the shape of reduced bills. That is, of course, looking ahead some 15 years; but I will come nearer home. That large sum of money will be given back to the consumers by degrees; they will not have to wait 15 years. Supposing we are enabled next year to reduce our selling price by 4d. on a sale of 46 millions, the consumers would get £800 in reduced gas bills. So you see the public have the prospect of getting almost immediately a further reduction of £800 per annum, or more than our surveyor estimates he can earn from the electric light.

But supposing the electric light comes in and prevents us extending our business as we are doing at present, it may have the effect of keeping the price of gas at its present figure; and instead of the gas company giving to the town a reduction equal to £800 per annum, the town itself will be the cause of the loss. But it might go beyond simply keeping the price of gas at its present figure. It might have the effect of causing it to be increased; for a company selling gas under the sliding scale may increase their price. Substantial reductions can be made in the price of gas only where there is a growing and

* From the *Journal of Gas Lighting*.

Digitized by Google

increasing business. I do not, however, wish you to infer that there should be no electric light in our towns, because I think there is plenty of room for both illuminants in many. But in our small towns—in the Eastern Counties, for instance—I think figures such as those I have given should be laid before the public before they are "rushed" into a heavy expenditure to supply the electric light. We can all work out these facts as they apply to our own towns; and they should be forced home to the consumers and ratepayers when they are tempted with a glowing electric lighting scheme, for it can generally be proved that they have already a far better source of income in the gasworks than can be offered by electricity. Besides, the electric light may not pay even in the hands of the local authority, but, on the contrary, money be lost, which would have to be made up out of the rates; and the poor ratepayer would have to pay his quota to maintain a light which at present can only be termed a luxury for the well-to-do. Thus the many may have to help to keep the electric light going for the few. I know several of our members have questions relating to this subject before them at the present time, and if they will discuss them and give us their experience I shall be glad that I brought the matter before you to-day.

In conclusion, I think that with such a large interest in the local gasworks as the public undoubtedly have in nearly every town they should be slow to embark on a new enterprise which, as we all know, so seldom pays its way, and which, on the other hand, may prevent the gas company from conferring such large benefits on the town as I hope I have shown can be, and generally are, conferred by a growing gas concern, whether it be in the hands of a corporation or a company.

Discussion.

Mr. J. Dixon (North Walsham) remarked that in the town which he represented they were threatened with the electric light. The question had been discussed by the District Council, but in that body they had not one practical member who understood anything about the subject. It was curious to notice how, as soon as this question of electric lighting came before local authorities, the members at once seemed to know all about it One member on their Council who was a crockery dealer stood up and said that, in his opinion the electric light was cheaper than gas, but he gave no statistics in support of his statement. Another member - a draper—dilated upon the beauties of the light, and, indeed, from all that was said, it seemed that at North Walsham they were going to have electricity for nothing. Being a member of the District Council, and the secretary and manager of the gas company, he made certain enquiries, and, on mentioning the matter to a friend, he told him of Cowpen, where the electric light had been adopted and had proved a failure. He (Mr. Dixon) wrote to the chairman of the Blyth and Cowpen Gas Company for some information on the subject; and he replied in this way: "I must first explain to you that our town is composed of two townships—namely, Blyth and Cowpen—each having a separate district council. The Blyth Council have never used anything but gas in their district. The Cowpen Council and gas company could not come to terms. Hence the adoption of electricity, which was used for six years, and has now been abandoned, the Council having agreed to burn gas on the same terms as Blyth. The reason why electricity has been given up was brought about on account of the great expense of Cowpen lighting in comparison with Blyth, and also because while the back streets of Blyth had lamps, the back streets of Cowpen were in darkness. The public dissatisfaction showed itself by the election of new members on the Council who went in for gas. If you want information from what would be considered a neutral party, you might apply to the clerk to the Cowpen Urban Council." Acting upon this suggestion, he addressed the clerk of the District Council, who answered as follows: "The lighting area within the district of the Council was, for a period of six or seven years prior to May 15 last, lighted by electricity, but it was an utter failure. The system of lighting was by overhead wires the lamps being fixed in such a position in the main thoroughfares as was thought would light up the various back streets in the district. This it did not do, and during the whole time the electric lighting was in existence one-half of the district was not lighted at all. The Council have now returned to gas, and for a small district like this the system of lighting by gas is much cheaper. Prior to returning to gas the Council invited tenders for the lighting of the district by electricity, and they found that it would cost from £6,000 to £8,000 to lay down a proper installation. This was found to be so expensive that they eventually decided to return to gas. Taking the whole matter into consideration, I have no hesitation in stating that for a small town gas is the cheaper mode of public lighting." The publication of these letters in the papers circulating in North Walsham gave, said Mr. Dixon, much annoyance to the advocates of electric lighting. When he became secretary of the gas company, some 10 or 12 years ago, the price of gas was 5s. 5d., and it had been reduced to 4s. 2d. The system the company had followed had been to reduce the price as soon as they possibly could after raising the dividend, and they had met the consumers (of whom they had now 150) in every way. For the public lighting they received £140 from the town, including lighting, extinguishing, and cleaning. The argument for the electric light was that if it was taken up this £140 would pay for everything. Now, in small towns like North Walsham there was not room for two lighting companies—the one would spoil the other; and people seemed to overlook the fact that if the consumption of gas increased the gas company could, without any additional labour, supply at a cheaper rate. The price of 4s. 2d. at North Walsham, he thought, would compare with other places of an equal size. He did not know what the charge was at Dereham.

The **President**: We have two prices—3s. for cooking and 4s. 6d. for lighting.

Mr. Dixon proceeded to refer to other information he had collected during his investigations, and stated that he could not (with the exception of Thetford) find any place like North Walsham that was supplied with electricity at a cheaper rate than gas.

Mr. E. G. Smithard (King's Lynn), speaking of the "high" dividends electric lighting companies were supposed to be going to make said he saw in the *Journal of Gas Lighting* that the Belfast Corporation had made a profit of £385 during the past year, not allowing anything for interest or sinking fund, and that the gasworks had provided all that was necessary in that respect. As most of the members were aware, he was formerly at Chelmsford, where they had a little electric lighting. As Mr Troughton had put it, there was not room in a small town like that (where the gas company's make was between 30 and 40 millions) for both electricity and gas. At Chelmsford it affected their consumption something like 8 millions. They made at one time a maximum of 40 million cubic feet, and now it was 32 millions, the consequence being that the dividends were also affected. They would find it was so in all little places where they were running the two lights together—they would both be affected. He did not think there were any electric lighting works outside London that were paying dividends. As to the comparative prices of gas and electricity, of course everything turned on the cost of the electricity. In the paper read by Mr. Tew at the Belfast meeting of the Gas Institute in 1893 he stated that electricity could not be manufactured for less than 5d. per unit. This figure, light for light, would compare with gas at 4s. 2d per 1,000 cubic feet—taking a unit as being equal to 100 cubic feet.

Mr. Dixon remarked that he enquired of the Incandescent Gaslight Company as to how to calculate the difference between the cost of gas and electricity, and they put it this way: take the price of 4s. 2d. at which they were selling gas at North Walsham, the supply of five cubic feet per hour for 1 000 hours would come to £1, whereas electricity, at 6d per unit, would work out (roughly speaking) to 30s.

Mr. Smithard added, as to the cost of public lighting at Chelmsford, that the gas company's tender (which was not accepted) was, he believed, for £650, while last year something like £1,000 was paid for lighting by electricity. He was not prepared to say that there was not more lighting, but there was not sufficient to account for the difference. He understood that the tender accepted for electric lighting was for about £850.

Mr J. Barton (Peterborough) asked to be allowed to make a few remarks as to street incandescent gas lighting. At the last meeting, he said, they had a little discussion on that subject, and since then he had been making some experiments with the light in clusters of three. As he stated at the previous meeting, up to that time the lights he had tried had been a failure. He had, however, altered the lamps; and he was pleased to state that he had obtained much better results - he thought he might say they were pretty well perfect. The illumination from the incandescent lamps in the streets was certainly quite as brilliant as the incandescent lighting in the shop windows. This had been accomplished in this way: he had altered the 60-c.p. lamps by taking out the glass (or solid) bottom and substituting a perforated zinc plate, and this seemed to get over the difficulty. The incandescent light in clusters of three (a single one was the same) required a greater supply of air than an ordinary gas flame. The 60-c.p. lamp consumed say, 15 cubic feet of gas in the ordinary way, while the 180-c.p. incandescent gas lamp consumed practically 12 cubic feet of gas; but this 12 cubic feet required more air than the 15ft. As to the cost of electricity compared with gas he found that an electric lamp giving 10 c.p., compared with gas at 3s. 4d. per 1,000 cubic feet, cost ½d. per hour; but an incandescent gas lamp costing the same gave them 80 candles, or eight times as much light. That was the difference between the cost of electricity as given by electricians and the cost of incandescent street-lighting.

Mr. R. J. Sharman (Wisbech) said that at the last meeting he rather ridiculed incandescent gas lamps for street-lighting, but since then he had been induced to try the light again. He had had a lamp introduced to his notice that was particularly adapted for the incandescent light; and he had tried one, as the cluster light had proved a failure in the old lamp. He placed it in one of the worst possible positions he could find, where it would catch the wind from all quarters. It was put up in November; but after a fortnight, some misfortune occurred to the mantle, and it went to pieces. A new mantle was fixed, and from the end of November to the previous Sunday night the lamp had never, to his knowledge, been out or touched. It was blown out on Sunday night, and he himself went to relight it. It struck him that the lamp was not particularly dirty, though, of course, a cleaning would improve it. He believed the Corporation were now advocating incandescent gas lighting, and the company were prepared to fix the lights for them if they desired it. But the great point was whether they could adapt the present lamps or would go in for a special lamp. The lamp he had tried had certainly so far proved a success. As to the electric light, he did not think they, as gas managers, ought particularly to set up their backs against it, seeing that the introduction of the electric light gave them an impetus to improve gas lighting in order to compete with it. He thought there would be room for both systems of lighting. If towns liked to spend their money in electric

Digitized by Google

lighting, let them do so; they would gain experience by paying for it. There was no doubt, when electric lighting was introduced, it woke gas companies up, and put them on their mettle, and had led to a considerable reduction in the price of gas The first duty of a gas manager was undoubtedly to the shareholders; but, at the same time, he ought to study the consumer, and produce gas at the least possible cost.

Mr. R. G. Shadbelt (Grantham) drew attention to the fact that the discussion had departed from the topic introduced by Mr. Troughton, which was something to this effect: Is electric lighting an equally good investment to gas? So far as he could see, he did not think it was. But gas managers were interested parties, and people did not take much notice of what they had to say on this subject. The only time at which they could object at all was when the local authority proposed to spend an amount of money as they would think wastefully, and then they could protest as large ratepayers. With this exception, he thought the best thing for them to do was to give electricity a fair field and no favour, and to meet it with truthful statements. He, as a gas engineer, could not help complaining of the untruthful statements electricians disseminated—it might be from over-enthusiasm, or indiscretion, or it might be that they did not understand the subject thoroughly. He thought the attention of electricians and that of the public ought to be drawn to this He knew of cases where the public were actually gulled, simply because they did not understand the subject. As to the adaptability of incandescent gas lights for street purposes, he might say that they had been experimenting with them at Grantham during the past winter. They had been guilty of not altogether adhering to the Welsbach lights, and they had tried a variety of kinds—whether rightly or wrongly remained to be seen. They put up about 30 burners, in groups of four, three, one double, and the remainder single, and in each case they took the lamp heads as they found them. His experience differed somewhat from that of Mr. Barton. Instead of increasing the air supply they had to reduce it Some of the bottoms of the lamp-heads were completely open, and the tops too. They found it advisable to check the air inlet at the bottom to prevent any flickering or sudden gusts of wind entering the lamp. The greatest importance, however, attached to the top of the lamp-head, as they found the down draught did more damage than the up draught. They checked this by putting in a little cone of perforated copper, or by surrounding the ordinary ventilator by copper or other equivalent according to the shape or size of the lamp. Out of the whole of the 30 burners they had not had a single failure. They had been able to adapt the whole of the lamp-heads, and the experiment had been an unqualified success.

Mr C. Ellis, referring to the electric lighting undertaking at Yarmouth, said the gas company had found it a rival; but, still, they had been making headway against it—last year something considerably more than the year previous. As far as the street-lighting was concerned, he did not know whether or not the Corporation had had sufficient of it; but since they had started the electric works the gas company had come to terms with them to light by incandescent lamps for three years the principal streets not illuminated by means of electricity. The arrangement was based on the consumption of ordinary street lamps—five cubic feet per hour; and they had something like 120 of the incandescent lamps in use These had been running for about 12 months, and he did not think the Corporation would be in a hurry to extend their arc lighting. The incandescent lamps were working very well indeed. They found it necessary to check the upward current of air, and by means of an ordinary leather collar over the copper tube they prevented the wholesale destruction of the mantles, which now averaged per lamp about four per annum.

Mr. Troughton, in the course of his reply, said he was pleased to hear Mr. Dixon give such an interesting account of Cowpen, as he happened to know that this place had been held up by parties advocating electric lighting as an example of prosperity. With regard to cheaper gas, that was one of the facts he wanted to press home in the short paper he had read. He thought it was of great importance to show the consumers and the ratepayers generally that by sticking to gas they would be helping to bring down the price. They could not go about preaching continually. But, as one speaker had mentioned, gas companies were large ratepayers, and when they were threatened with the electric light by the local authorities then was the time to educate the ratepayers. The reports made by the electricians were too glowing—at any rate, when looked at from the gas manager's point of view, and the public required enlightening as to the advantages that were to be derived from gas in order that they might make a fair, unbiassed comparison between the two systems. With reference to the statement made by Mr. Dixon as to Thetford, the electric lighting plant there, he believed, was originally put down for lighting the works of Messrs. Burl; and the installation was found to be of sufficient capacity for a few outside customers. It was not therefore fair to take Thetford as a town that was lighted by electricity.

Mr C Snelling (Thetford) intervened with the remark that one of the largest customers had returned to gas and was now using the incandescent light. He also mentioned that the gas company had lost the lighting of the Great Eastern Railway Station, and that the price of gas was 5s. per 1,000 cubic feet for lighting and 4s. 6d. for cooking purposes.

Mr. Troughton (resuming) referred to Mr. Smithard's remarks as to the electric lighting of Chelmsford. He pointed out that the light was supplied by a large local firm of electrical engineers (Messrs. Crompton), and said if they could supply it cheaply anywhere they would do so at home for an advertisement. Still, as Mr Smithard had shown, the townspeople were foolish enough to pay considerably more for the light than they would have to do for gas.

Mr Ellis: Recently the accounts of the Yarmouth Corporation electricity department showed a balance of £790 on the wrong side.

Mr. Smithard, replying to an enquiry as to the financial results of electric lighting at Chelmsford, said there was an admitted loss, but its extent was not publicly known.

Mr. Troughton (continuing) pointed to the results of the working of the Worcester electricity department as already recorded in the *Journal*, and also alluded to the fact that there were dividend-paying electric lighting companies, but they all occupied specially favoured districts, with numerous consumers on a short line of cable. But if a company started in a small town such as East Dereham, where the residents were far apart, it would cost a considerable sum of money to lay down the cables, and there would be a large proportion of leakage. He believed the leakage at Worcester last year was 25 per cent of the electricity generated. He was glad Mr. Barton had given them a few useful figures relating to the incandescent light, because that at the present time was a strong competitor of the electric light. Mr. Sharman had expressed the opinion that there was room for both gas and the electric light. Seeing, however, that, if there was a loss on the latter, the ratepayers had to "pay the piper," his (Mr. Troughton's) view was that, if they could prevent the light coming into the small towns they represented in the Eastern Counties, they would be doing the ratepayers a great kindness.

INSTITUTION OF ELECTRICAL ENGINEERS, April 16.

SIR HENRY MANCE in the chair.

In the discussion on Mr. Dane Sinclair's paper on "The Working of a Telephone Exchange,"

Mr. Addenbrooke followed Mr. Preece, remarking that his experience in connection with the Telephone Company covered the period of 1883 to 1886, when the company were getting things into shape, and when many of the problems that were now being discussed first began to make their appearance. Mr. Addenbrooke then went on to compare the time necessary to send a message and get a reply by post, by telegraph, and by telephone, with the view of enforcing the conclusion that an extremely rapid service was a much less important matter than thoroughly good speaking. Owing to the kindness of Mr. Preece, he had had the opportunity of trying both the Dublin and Paris lines, and he found that the speaking over them was better than over the majority of the company's lines not more than two miles long. There had been a great improvement in this respect in London from the double wire, but it was in the country, not in London, that the telephone had its greatest value, and there the difficulties did not meet them with which they had to battle in London, though perhaps they might be approaching them in such places as Manchester and Liverpool. There was thus a population of 30 millions which could be served with apparatus which had been all worked out. In a manufacturing district, for instance the works might be two miles distant from the nearest town, yet the population was dense, and the trunks would be only a few miles long. Under such conditions, with a good service, it ought to be almost like speaking to the next room. If that could be assured, it would not be necessary to be always able to get through in half a minute. If a subscriber could get through in five minutes it was all that was wanted, provided that the speaking was perfect and he could always get the answer he wanted.

Mr. Hawes did not see how certain troubles could be got over with a flat board. The system had now to work constantly, and when any repairs where required they had to be done while the switchboard was at work. Then as to the size of the board. For 6,000 subscribers it would be more than a yard square, and it would be impossible for the operator to reach across while sitting, and it certainly did not expedite the service for the operator to keep jumping up and down. Then, again, in pulling out one cord there was a danger of pulling out another with it. As to up and down trunk wires, when there were a certain number of junction wires between exchanges it was really better to use one-half for messages one way and one-half for the other way. It might not be quite so economical, but the work was done much quicker. He could not agree with Mr. Addenbrooke on the subject of the time taken to get through. Even in London he would be extremely annoyed if he had to wait five minutes for every call—and, of course, he had not to do so. Perfect working might be the result of a small number of subscribers, and an absence of junction wires made the service very rapid. As to what had been said about Berlin and the advisability of making the subscriber do as much as possible of the work, it was certain that in such a case the service seemed more rapid than it was, for when a man had something to do he did not notice that the time was going; on the other hand, the disadvantage was that if the connection was not made, the subscriber might go on ringing for ever and nothing would happen.

Mr. Somerville said with an upright board the operator was expected to stretch 3ft. 3in. on each side without interrupting her neighbours. She might be able to do it with plenty of elbow room, but with four operators the space allowed her was only 19½in. With a flat board it was much worse. To make some connections it was necessary to insert a jack at a distance of 4ft. Now, with eight operators at work this was impossible, and as a matter of fact the operator asked and received assistance for

Digitized by Google

25 per cent. of the connections. Moreover, in the system described by Mr. Sinclair the subscriber's conversation was liable to be overhead by the operator and the subscriber annoyed by the question, "Have you finished?" It was pleasing to hear Mr. Sinclair advocate the use of flat boards and the call-wire system, although results seemed to indicate that his advocacy, until quite recently, must have been of a very mild type. Doubtless, however, he would by-and-by advocate their use even in London, his present objection being without foundation, as there was no reason for the King's Cross operator desiring to communicate with Lime-street doing either of the things he thought inevitable—viz, cutting herself off from the call wire, or joining her call wire with its 50 subscribers to the call wire to the City.

Mr. Dane Sinclair said that the speeches had occupied so long that he would hardly have time to reply to all the points raised. Mr. Kingsbury had condemned the call-wire system. If he had taken his experience of it from the Law system, that would not be surprising. It had been necessary to clear it out and replace it with the Mann system. With the Law system every subscriber had the power of breaking into the circuit and cutting off all who were beyond him. That and the make and break in the switch was too much for the system But when it was altered to the other way so that 20 might tap on, but the last could not cut the others off but had to wait his turn, the state of things was different. The question of the distance that could be reached was gone into experimentally, and it was found that the difference between the upright and the flat board in that respect was so small that there was absolutely nothing in it. Any board had its own difficulties, and the question was only one of choice between them. Increasing the number of jacks while operating was going on was not necessary. A few hours' work in the evening would be enough to put the jacks into place, and it was a more simple matter to lift out a row on the flat than on the upright board. The point referred to by Mr. Preece as to doing work among the wires underneath the flat board, the alleged difficulty came to this: that it would have to be part of the training of an engineer to behave himself when in close proximity to one of the opposite sex. They had carried it out in practice, and he (Mr. Sinclair) had not heard of any detrimental results. He considered that great credit was due to Mr. Preece in that he had been an early and earnest champion of the metallic circuit. There was, however, the commercial side of the question to be considered. The company were at that moment metallic circuiting Manchester, because the Corporation there had invited them to go underground. In describing what was done at Berlin, Mr. Preece had quoted the very reason why he (Mr. Sinclair) liked the call-wire system. It threw the responsibility of the working into the hands of the subscriber, but with the difference that if the subscriber at the other end did not answer, the caller was told so With the battery system of the Post Office the mechanical working was no doubt perfect; but when the signal was given at the exchange what happened after that was at the command of the operator. With the call wire the caller had got her and she was bound to give him some reply, while with any ringing system he would have to wait until she chose to be ready. In the one case the subscriber commanded the situation; in the other he did not.

The usual vote of thanks was passed to the reader of the paper, and the **Chairman**, in closing the proceedings, remarked that the most satisfactory point brought out was the rapid increase of the double-wire circuit. That involved a matter of great interest to electrical engineers who might have to do in any way with electrical tramways, and he hoped that Mr. Gavey in his paper next session would be able to tell them what was expected and to give them some rule in that respect by which an electric contractor could work.

The next meeting is on April 30, when Mr. Langdon's paper on railway telegraphs will be taken.

LEGAL INTELLIGENCE.

THE ST. PANCRAS EXPLOSIONS.

In the Queen's Bench Division, on the 17th inst., the case of Houldsworth *v.* the Vestry of St. Pancras came on before Mr. Justice Cave and a common jury.

The plaintiff's claim was for injuries caused in February, 1895, by an explosion in a culvert under Gee street, in possession and under the control of the defendants, and in which a quantity of coal-gas had been allowed to accumulate It was plaintiff's case that a spark from the defendants' mains ignited the coal-gas, and there was an explosion, in consequence of which the plaintiff suffered shock to the system and acute inflammation of the optic nerve of the right eye. The defendants denied that the explosion was caused in the way alleged and that the injuries the plaintiff suffered were caused by the explosion. The defendants also alleged that the culvert was constructed with reasonable care and as required by law.

Mr. Witt, Q.C., and Mr. John Raymond appeared for the plaintiff; and Mr. Lawson Walton, Q.C., and Mr. Albert Gray for the defendants.

The **Plaintiff** was called, and gave evidence that as she was walking along she heard an explosion, felt a numbness in her feet, and was very frightened. A fortnight afterwards she had bad pains in her head, and her right eye became bad.

Dr. Ernest Clarke, ophthalmic surgeon, gave evidence as to the condition of the plaintiff's eye on March 12. In cross-examination he said neuritis, from which plaintiff was suffering, was common in both eyes, but more uncommon in one. In one eye the more obvious cause was a blow.

Mr. Tasker, an electrician, gave it as his opinion that the ventilation was imperfect, as there was no outlet for the gas. He also considered the insulator was imperfect, being only 1in. in vertical length instead of 4in. or 5in The bearers were faulty, being of wood. Wood was always liable to absorb moisture, and an alkaline incrustration would then be liable to be formed. In cross examination the witness said the system used in St. Pancras Vestry had been approved by the Board of Trade.

For the defence **Mr. Marcus Gunn**, ophthalmic surgeon, said in his opinion the fact that the neuritis was only in one eye tended to show it was not caused by the explosion.

Mr. Lawson Walton, Q.C., for the defendants, contended that the inflammation of the optic nerve was not the result of the explosion. Further, that as the Vestry had been empowered to lay down wires charged with electricity, if they carried out the work with reasonable care, they were not liable. Modes of ventilation which were thought admirable some time ago were not now thought to be good Wood bearers were net, at the time these were put down, thought to be insufficient. No negligence on the defendants' part had been shown.

Mr. Witt, Q.C., contended that the defendants were liable as creating a nuisance on the highway. He cited Shelfer *v.* City of London Electric Lighting Company (1895, 1 Ch, 287).

The jury found for the plaintiff, damages £105 and judgment was given accordingly, but a stay of execution was granted.

CLAIM FOR ELECTRICAL APPLIANCES.

At the Westminster County Court on Monday, before his Honour Judge Lumley Smith, Q.C., the case Swinbourne *v.* Andrews was tried.

The plaintiffs, a firm of electrical engineers, sought to recover payment of an account in respect of a dynamo and a number of arc lamps supplied to the defendants, Messrs. Andrews and Co., who are also electrical engineers. The plantiffs' case was that the arc lamps, which were made to order, were of a very peculiar character and involved a good deal of extra expenditure in their manufacture. They were made to defendants' own drawings, and it was not until payment was pressed for that any complaint was made either as to their price or the working.

The defence was that both the dynamo and the lamps were very faulty in construction, and that the prices charged were much in excess of those agreed upon.

His **Honour**, having heard the evidence of several witnesses, expressed the opinion that it was a case which might very well have been settled between the parties, but inasmuch as it had come before him he must decide it. He should cut the plaintiffs' claim down to £45, for which amount they would have judgment with costs.

COMPANIES' MEETINGS AND REPORTS.

NORWICH ELECTRICITY COMPANY.

The annual meeting of this Company was held last week at Norwich, Mr. F. W. Harmer presiding.

The directors' report stated that the success realised during the first 15 months of the Company's working had been fully maintained during the past year. The demand for current, both for lighting and motive power, had continued to increase in a most satisfactory manner, the number of customers being now considerably in excess of that of 1894. A large number of private houses had been wired, and the directors thought that at length the public were beginning to appreciate the enormous advantages of electricity as compared with any other method of lighting. During the year upwards of two miles of new mains had been laid, making the total length about seven miles. The revenue account for the year showed a credit balance of £2,847. 3s. 1d., to which must be added £112 5s. 8d., brought forward from last year, making a total of £2,959. 8s. 9d. From this was to be deducted £749. 3s 5d. for interest on debentures, etc., leaving a balance of £2,210. 5s. 4d. With this the directors propose to declare a dividend of 3½ per cent., free of income tax, amounting to £991. 12s 10d., to place £1,100 to depreciation account, and to carry forward the balance to next year.

The **Chairman**, in moving the adoption of the report, said if the shareholders compared this year's report with that issued 12 months ago they would find it to be most satisfactory. The income had increased £2,000—that was to say, from £3,786 in 1894 to £5,845 in 1895, and this at a much smaller expense, for while coal cost £994 in the former year it was only £1,300 in the latter, and in salaries the increase had been in the same proportion. Of course, the expense to which they were put was not for coal, but for interest on capital. That increased fast, and he was afraid it was likely to do so. But there was this to be said, that the directors had not only learned how to make electricity, but how to do so at a profit, which was still more important.

Mr. H. S. Patteson seconded, and the report and accounts were then adopted.

The retiring directors and auditors having been re-elected, the **Chairman**, in reply to a vote of thanks, said that it had been to him a labour of love to do all he could for the Company, for it was congenial to his tastes, and he was glad the thing had been successful.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY.

The second ordinary general meeting of the Company was held on Wednesday at the Cannon-street Hotel, Mr. Wm. Addison in the chair.

The **Chairman,** in moving the adoption of the report and statement of accounts, which were taken as read, and which were published in our issue of last week, congratulated the shareholders on the satisfactory progress of the Company, and especially on the realisation of what had been for years the hope of the directors in being able to recommend out of the net profits of the year a dividend at the rate of 5 per cent. With reference to the loss of their exchange in Colombo, the directors had been in continuous negotiation throughout the year with the Government of Ceylon, which had already given them notice that it would not renew their license about to expire at the end of December, 1895. With all due respect to the Government, he thought they had been treated in this matter in a way that was very discouraging to private enterprise and unfair to a company which had invested a considerable sum in the colony, and was ready to invest still more freely if it could have obtained continued security from the Government. Nor had the directors received that measure of support from the Colonial Office which, under the circumstances, they felt they were entitled to ask. In the end, the Board had to accept a sum which represented only a small part of the value of the exchange, upon which they had spent in cash £4,856 odd, to which must be added goodwill and compensation for forcible dispossession. The suspense account in the balance-sheet in regard to the Colombo exchange amounted to £2 481 odd. This sum could easily be liquidated by the profit on their consols if they were to be sold, together with the amount now proposed to be carried forward, after paying the dividends recommended. As, however, the matter had only been finally closed in the current year, they had thought it best to carry the amount to a suspense account, leaving its ultimate adjustment for future consideration.

The motion was seconded and adopted.

Mr. B. St. John Ackers and Mr. G. B. Frost were re elected directors. The auditors were also re-elected, and the meeting terminated with the usual votes of thanks.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY, LIMITED.

The report of this Company for the half-year ending December 31 states that the gross receipts, including Government subsidies, amounted to £311,582, against £261,322 for the corresponding period of 1894. This large increase is mainly due to the exceptionally heavy traffic transmitted to and from Western Australia in connection with the gold-mining industry that has recently sprung up in that colony. The working and other expenses, including £20,713 for cost of repairs to cables and expenses of ships, absorbed £84,044, against £89,740, leaving a balance of £227,538. From this is deducted £4 318 for income tax, £20,000 transferred to the fire insurance fund, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving as the net profit £171,325, which, with £70,504 brought forward, shows an available balance of £241,829. One quarterly interim dividend of 1¼ per cent. has been paid, and it is now proposed to distribute another of like amount, making, with the interim dividends paid for the June six months, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent.; making a total distribution of 7 per cent. for the whole of 1895. The balance of £129,329 has been carried to the general reserve fund, which now stands at £561,546. The system has been strengthened by the renewal of 340 knots of the New Zealand (original) cable and 109 knots of the Tasmanian (original) cable. The cost of these renewals, amounting to £38,733, has been debited to the general reserve fund, together with £186,044, the balance of cost of the alternative Singapore-Hongkong cable. Further extensive renewal work will have to be carried out during the current year. In accordance with the provisions of the trust deed, dated May 10, 1879, 409 of the 5 per cent. Australian Government subsidy debentures, amounting to £40,900, were drawn by lot on April 1 for payment at par on July 1 next. With a view to placing the tariffs on a more uniform and satisfactory basis, the directors have decided to reduce the local rates as and from July 1 next. The immediate effect will certainly be a considerable falling off of revenue, but it is hoped that the lower rates will lead to such an increase of business as may eventually recoup the initial loss.

The general meeting of the Company takes place on April 29 at two o'clock at Winchester House, E.C.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY, LIMITED.

The report of this Company states that the accounts are sub mitted in conjunction with those of the "Metall" Company, and show that an important reduction has been made in the capital—the whole of the £25,980 second debenture stock has been redeemed, and 10,337 ordinary shares have been handed by the holders for cancellation as a donation to the Company in order to improve its position. The benefit to both preference and ordinary shareholders by this reduction is apparent, as it has enabled the directors to write off the deficit standing to the debit of the Company, and to reduce the value of amount standing to patent account by £1,441. The amount due to this Company from the "Metall" Company is now £19,008. The two mortgages which are held as security are now in the hands of Lord Farrer of Abinger and Mr. J. R. Holland, as trustees for the debenture holders. The directors have agreed to waive one-half of their fees for the past year. With regard to the "Metall" Company's accounts, it will be seen that the capital has been reduced to 600,000 marks (or £30,000) in order that the loss standing to the debit of profit and loss should be written off: also that £2,512 has been spent in new plant. This includes, amongst other things, two new draw benches, which were started at the beginning of this year. With regard to the trading account, the sales are more than double those of 1894, and a comparison with the trading account for that year will show that notwithstanding this and the fact that the stock-in-hand has increased by £2,200, the manufacturing purchases (excluding copper), wages, etc., have increased only in a very small proportion. The transfer of a loss in 1894 of £9 to a profit of £3,654 is satisfactory. The directors regret that a loss of £1,575 is shown upon the year's working, but they desire to point out that this has been brought about by the large sum of £2,554 written off as depreciation on the various assets. An arrangement has, however, been made whereby in the future only such sum as actually represents fair wear and tear shall be written off. With regard to the work generally the experience gained at the factory shows that to produce the highest quality copper, it was advisable to work at a lower rate of deposit than was at first adopted; therefore the plant erected does not produce the amount that was anticipated, and it is of importance that the number of tanks be increased. This can be done at a comparatively small cost, and it is proposed to put down 16 additional large tanks at an early date. It is necessary to issue a further amount of debenture stock to pay for the new plant, the additional copper required, and to pay off the overdraft at the German bankers, which is guaranteed by two of the directors and two shareholders. The directors consider that the business warrants the expenditure, and they are assured by the works manager that more than sufficient orders will be offered to keep the new plant at full work.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Oberjesingen (Wurtemburg).—Tenders are invited by April 27 for a church lightning conductor. Particulars from the Konigl. Evangel, Pfarramt.

Ixworth (Suffolk).—Tenders for lighting Ixworth streets must be addressed to Mr. S. M. Randall, clerk to Parish Council, Ixworth, and reach him by May 15.

Prague (Austria).—Tenders are wanted by June 1 for an electric lighting central station for the city of Prague. Application should be made to the Stadrath, Prague.

Bruges.—Tenders are wanted by May 13 for the supply and erection of an electric water-level indicator for the River Lys. Particulars from Le Gouvernement Provincial, Bruges, Belgium.

Stralsund (Germany).—Tenders are invited for installing the electric light on a steamer. Particulars for 1·50 marks (1s. 6d.) from the Werftbureau, Konigl. Wasser-Bauinspection, Stralsund.

Chapelle-lez-Herlaimont.—Tenders are wanted by May 15 for erecting three lightning conductors on the Hôtel Communal. Address, M. le Bourgmestre, Chappelle-lez-Herlaimont, Belgium.

Sunderland.—Tenders are invited by April 29 for an evaporative tubular surface condenser. Particulars can be obtained from the borough electrical engineer, at the supply station, Dunning-street, Sunderland, on deposit of one guinea.

London, E.C.—The Great Indian Peninsular Railway Company are prepared to receive tenders for the supply, among other stores, of sulphate of copper and miscellaneous wire by April 30. Particulars may be obtained at the company's offices, 48, Copthall-avenue.

Hampstead (London).—The Vestry of St. John's want tenders for a 300-kilowatt steam alternator, feed-water heater, tank, switchboard, etc. Particulars can be obtained from the vestry clerk, at the Vestry Hall, Hampstead, and tenders must be ready by April 27.

Leipzig.—Prices are wanted by May 2 for about eight tons of sal-ammoniac, four tons of sulphate of copper, about seven tons of zinc, and a quantity of copper wire and telegraphic apparatus and stores for exportation during 1896. Application should be made as speedily as possible to Hachmeister und Thal, Leipzig, Georgenstrasse 5.

Lisbon.—Tenders are wanted by the Royal Portuguese Railway Company for the supply of articles and material necessary for the upkeep of their electric lighting. Tenders must be sent to the chief engineer, at the company's stores at Santa Apolonia Station, Lisbon, by May 6, and particulars can be obtained there, or at the company's Paris offices, Rue de Châteaudun 28.

Eston.—The Eston Urban District Council invite schemes for lighting the district by electricity. Such schemes to embrace (*a*) plan and estimated cost, (*b*) annual working cost and maintenance. Plan of the district may be seen and particulars obtained of Mr. T. W. Stainthorpe, A.M.I.C.E., district surveyor, Grange town, Yorkshire, to whom the plans, etc., must be sent by May 1.

Lima (Peru).—Tenders for the electric lighting of the city of Lima will be received up to June 1 next at the Peruvian Legation, 13, Comeragh-road, West Kensington, W., where applicants can obtain a memorandum explaining the local conditions. The

Digitized by Google

tenders will be opened and considered by the Municipality of Lima, which reserves to itself the right of selecting that which is most approved or rejecting all if it thinks fit.

Hull.—Tenders are required for the supply of coal from May 1 to December 31, 1896, for the Electric Light Committee in accordance with the conditions set forth in the forms of tender, which may be obtained at the electric light station, Dagger-lane. The contractor will have to enter into the usual form of contract required by the Corporation. Tenders, endorsed "Steam Hards for Electric Light Station," should be sent under seal to the Chairman of the Electric Light Committee, Town Hall, Hull, by noon on 30th inst.

Oldham.—The Technical Education Committee of the Oldham Corporation are prepared to receive tenders for the wiring of the Technical School, Ascroft-street. The installation will consist of 34 arc lamps. Specifications and plans can be obtained from Mr. S. Wilmott Newington, borough electrical engineer, Gas-street, Oldham, on payment of £1. 1s., which will be refunded on return of the specification, accompanied by a bona fide tender. Tenders, endorsed "Tender for Wiring," must be sent to the office of Mr. A Nicholson, town clerk, Town Hall, Oldham on or before noon, May 1, 1896.

St. Helier (Jersey).—Persons wishing to establish a lighting station in the locality for the purpose of supplying electric, gas, or other forms of light, for both public and private use, are requested to communicate with Mr. P. Baudains, constable, Town Hall, St. Helier, Jersey. All such preliminary communications are to state (1) form of light—*i.e.*, whether electric, gas, etc.; (2) in the case of electric light, what methods of generation and distribution would be adopted; (3) proportionate price for public purposes and private lighting; (4) general conditions under which tenders would be made. All necessary information will be supplied on application.
